in the New York *Herald*, to show that Greater New York spent fifty millions of dollars every year on charities, and that, according to a conservative estimate, fully fifty per cent. of the donors' money was diverted from the purpose for which it was intended and was practically filched from the poor, to whom it rightfully belonged. Again, according to one author, Dr. J. B. Huber, one might find in large numbers at dispensaries such people as actors, gamblers, bartenders, policemen, farmers, prosperous businessmen and those owning houses, lawyers, and perhaps even a stray railway president. According to another author, fully fifty per cent. of the applicants in the reception, room of a well-known institution, which he dubs "the Diamond Dispensary," were well dressed: ten per cent. were finely dressed; more than half of the men bore no evidence of poverty: and among the women there was an attractive display of fine millinery—yet all obtained the free treatment supposed to be given only to poor persons. A reporter on one of the daily papers, in describing what he saw at a well-known "clinic," stated that not more than one in fifty was at all shabbily dressed, a large majority were fairly well dressed, one-third of them were quite presentably dressed, and perhaps one-fifth were positively well dressed. The reader of the paper said that he knew of a man who paid an enormous rent in a fashionable apartment house near Central Park, and who spent many thousand dollars a year on living expenses, yet he went to what has been so aptly termed "the Diamond Dispensary," on the plea that his expenses were so heavy that he could not afford to pay a fee to a doctor. "Certainly," the author continues, these instances "show the spirit in which charity is asked for and accepted; it is largely a desire to save money, without apparently thinking that self-respect is lost in the effort or that a wrong is done to the really poor and to the physician, who is certainly as much entitled to his hire as are the clergymen or other members of the community, as he too has social obligations to fulfil." More than this, as Dr. Schweck had well said in the Philadelphia *Press:* "People of means who go to charity dispensaries and receive treatment free of charge, representing themselves to be too poor to pay for medical services, commit a criminal act, for they obtain what they are not entitled to and do it under false pretences."

Another and important aspect of this subject had been revealed in a communication from Dr. G. M. Roe, medical superintendent of the Boston City Hospital, to the Boston *Herald*. He says: "It is a generally accepted fact among people who have had large experience in doing charitable work that the first thing that a man or woman will accept as charity is medical attendance. They will accept free service from the doctor when you could not prevail upon them to accept rent or fuel or anything of the kind as a gift. The acceptance of gratuitous medical attendance is the first step toward pauperism. There is already a tendency toward what is generally known as 'nationalism'—a belief among the common people that the city and the State owe them a living, and that medical attendance, among other things, should be furnished them by common taxation, regardless of their financial standing as individuals." Again, as Dr. J. J. Stevenson had expressed it in the *Mail and Express:* "If recovery from disease be secured at the expense of self-denial, the memory of the cost will lead in ordinary cases to care that a recurrence of disease and attendant expenses may be prevented. But if the careless feel that treatment, medicine, and even diet can be had simply for the asking, there can be no reason for resisting the natural tendency to neglect the laws of health. . . . It is not surprising that the reckless poor see in such careless giving an acknowledgment of the unequal distribution of wealth, and believe that it is founded on injustice; nor is it strange that the anarchist's cry is not for opportunity to earn by labor, but for such distribution of wealth as may enable all to enjoy the luxury of idleness."

The following are the conclusions arrived at by Dr. Wiggin after a critical review of the subject: (1) That medical charity, as at present administered, is an unqualified evil and is seriously menacing our existing social conditions; (2) that the application for free treatment of those able to pay the physician a moderate fee for his services robs the really poor; (3) that all medical charitable institutions should be under the direction and control of State and local boards of charities, which should have the power to enforce their rules; (4) that all applicants for medical charity should be investigated by local charity boards, and the unworthy excluded; (5) that no medical charitable institution should be allowed to charge nominal sums for medicines or appliances; (6) that all physicians connected with charitable institutions should be paid for the service which they render; (7) that it should be made a misdemeanor, punishable by fine, for any person to receive free medical treatment by reason of false representations as to financial condition; and (8) that State or city aid should not be granted to private medical charities.

Dr. Wickes Washburn, of New York, opened the discussion. He referred to the investigations made, from January 1, 1897, to the present time, by the Charity Organization Society, of cases sent to it by several dispensaries and out-patient departments in this city. Out of a total of four hundred and forty-three cases investigated in this way, one hundred and eighty-nine, or a trifle over fifty-five per cent., were reported to be unable to pay a moderate fee. The decision as to the financial condition was based on the following data: (1) the total income of the family; (2) the number in the family; (3) the ages of the children—whether old enough to work or not; (4) who, if any, in the family were out of work, and how long; (5) if working, the wages paid; and (6) the general impressions of the visitor. After reviewing the work connected with the presentation of "the dispensary bill" to the legislature last winter, the speaker suggested that section six, empowering the State board of charities to enforce the regulations contained in the act and to punish those who wilfully violated its provisions, might be made less objectionable by requiring "the approval of the judge of the supreme court sitting in the county where such failure to comply with the rules had occurred."

John Harsen Rhoades, Esq., continued the discussion. He said that at the outset he felt compelled to criticise the medical profession sharply, but in a kindly spirit, for it was in large measure to blame for the existing abuse of medical charity. One cause was to be found in the great multiplication of hospitals and dispensaries—not always from the most worthy motives. This multiplication was too often brought about through the ambition of young medical men to attach themselves to those institutions or to found new ones, that they might gain not only experience, but reputation and a livelihood. Another cause of the present state of affairs was to be found in the natural repugnance of physicians and others to prying into the private affairs of those who may quite possibly be worthy objects of charity. Another reason was the secret willingness of many young practitioners to conceal the facts for purposes of private gain. Still another and a very important cause was to be found in the absence of a "clearing-bureau," where all cases and applications for charitable relief of all kinds, medical and otherwise, could be investigated for the benefit of all charitable institutions of all classes and sects. Without such a bureau the work must necessarily be dupli-

cated many times and at great expense and disadvantage. Each institution should share the expenses of the bureau in proportion to the number of patients recorded against each. If the law compelled each institution to send weekly lists of all applicants to such a central bureau, it was more than probable that the result would be the disclosure of an appalling amount of fraud and a reduction of fifty per cent. in the number of those applying for charity. He had long been an advocate of a paid staff at such institutions, provided that the physicians from a certain grade down were permitted to remain only a specified time. If the existing system of medical charity were allowed to continue, we would soon build up a nation of paupers.

Dr. J. E. Janvrin, of New York, dwelt upon the circumstances leading up to the presentation of the dispensary bill, particularly upon the interview which a committee of which he was a member had had with Governor Black. The executive had objected to the bill ostensibly on the ground that it gave too much power to one association—the State board of charities. Incidentally he had expressed the belief that any one who was wealthy had a perfect right to establish a medical or other charity, and educate young men, rich or poor, without any fees whatever, and if necessary even to assist them afterward in obtaining business. When asked if he would have approved of such a state of affairs when he was a young lawyer, he replied: "As a lawyer I should have objected to it." The speaker said that he had long felt that dispensaries and hospitals should be conducted more on business principles, and that the medical officers should be properly remunerated. He thought the proposed amendment of section six of the dispensary bill would, if enacted, give rise to many contentions and much annoyance.

Dr. F. D. Ferguson, of Troy, said he thought that from the lawyer's standpoint legal objections to the bill might arise, particularly in regard to those institutions that had been incorporated prior to the establishment of the State board of charities.

Dr. Leroy J. Brooks, of Chenango County, thought that an important factor in causing the enormous increase of applications for medical charity in the period since 1870 was the enormous increase in the number, clinical facilities, and influence of the medical schools. From information recently received from Albany, he had been led to believe that the medical schools were exerting a persistent though perhaps silent opposition to this dispensary bill.

Dr. Eden V. Delphy, of New York, suggested that a remedy might be found in an ethical restriction, making it contrary to the dignity of the profession for a member to act as a physician in a dispensary which permitted abuse of medical charity. The attitude of those managing the medical schools would suggest the necessity for some retaliatory measure on the part of the rank and file of the profession, such as avoiding these men in consultations.

Dr. Manley had no faith in legislation as a remedy for the abuse; the evil was not with the dispensary managers, but with the medical profession. More than this, he did not feel that its members could be depended on to enforce penalties against brethren in the profession who transgressed in these matters.

Dr. J. R. Macgregor, of New York, said that the question was one of fraud on the part of individuals of the community who imposed upon the profession. We must have the authority of law if we expected to do away with such imposition. He thought if the dispensary bill had been passed earlier in the last session of the legislature, it might have been passed even over the governor's veto. Probably the real reason the executive refused to affix his signature was the pressure brought to bear upon him by the medical colleges.

The Status of Medicine.—Dr. Nelson L. Worth, of Kings County, presented this paper. He said that if half the care were bestowed upon the passage of proper laws regulating marriage (and hence indirectly the procreation of the species) that was given by the ordinary farmer to stock raising, an enormous gain to the race would be easily apparent in the lifetime of a single individual. The reader of the paper then propounded the following suggestive questions: How much of the cause of disease did we yet know? Was it the germ or the toxin of the germ? Could the germ be destroyed without injury to the individual? Could we positively cure the disease by controlling the toxin? Was consumption curable now? Was it any more so than before the discovery of the bacillus of tuberculosis? Did as many subjects of phthisis get well now as before Koch's great discovery? Was not the practice of medicine in relation to phthisis more unsettled and ineffective now than before the discovery of the tubercle bacillus? Was not the neglect of hygienic and climatic and medicinal methods doing more harm than the direct germ treatment was doing good? In conclusion, he expressed the belief that the medicine and surgery of the closing years of this century were largely unstable and experimental.

The Growth of Commercialism in Medicine.—Dr. John Shrady, of New York, read a philosophical essay on this subject. He thought that the older practitioners saw more of gratitude and tender remembrances than those practising at the present time. He then gave a humorous description of the various subterfuges resorted to by the *fin-de-siècle* physician in order to secure for himself a proper amount of advertising without apparently committing any breach of the code of medical ethics.

The President's Address, "The Causes of the Decline in the Average Income of General Practitioners of Medicine."—Dr. Charles Phelps, of New York, presented his address, taking for his theme the above topic. He said that the earnest effort made before the last legislature to obtain relief from certain abuses of medical charity was proof of the general diminution in the incomes of physicians, particularly in this city. But this was only one cause; there were others, and it should be remembered that medical practice, like other things, was largely regulated by the well-known principle of supply and demand. It was also easily demonstrable that the amount of sickness in our community had notably diminished. This increased healthfulness, even the public was now willing to admit, was largely due to the advances made in the bacteriological and pathological laboratories, and to a better control over disease by the proper sanitary authorities. Thus, epidemic dysentery had become unknown here, and variola was practically unknown. The maintenance of a reasonable standard of purity for milk and proper supervision of plumbing had done much to diminish gastro-intestinal disorders. The effect of the improved cleanliness of the streets on the public health was, in his opinion, problematical. Among other causes mentioned were the general business depression, the want of a proper adjustment of the fees to the incomes of the patients, the business methods in vogue at the present time, the more complicated mechanism for the treatment of disease, and the increasing custom of sending patients to sanitaria and hospitals. The speaker concluded by expressing the belief that the remedy would not be found in legislation except by an inordinately rigid and distasteful surveillance, which would be unbecoming an honorable profession.

A Study of Alcohol, Tobacco, Tea, and Coffee as Causative Factors in the Production of Nervous Disorders.—Dr. Charles E. Lockwood, of New York, read this paper. He said that in the United

States in 1895, the total amount of distilled spirits consumed was 78,823,561 gallons; of wines, 19,644,000; of malt liquors, 143,232,106 gallons. Statistics were also quoted to show that the consumption of tea and coffee has decreased, while the use of malt liquors has greatly increased. In brief, it might be said that alcohol is a stimulant in moderate, and a narcotic in toxic doses: tobacco is a stimulant and sedative in moderation, but relaxing and paralzying in toxic doses; while coffee and tea are nervous stimulants in moderate doses, and depressing but not narcotic in toxic doses. Recent experiment seemed to prove that small quantities of alcohol do not interfere with gastric digestion, and at times even assist it. Wines retard pancreatic and salivary digestion, and malt liquors retard salivary digestion. Alcohol first attacks the cerebrum, then the cerebellum, cord, and automatic centres in the medulla, in the order named. Alcohol acts on the nerve cells directly as a functional poison, and hence the subsequent depression. According to Gowers, epilepsy is occasionally an effect of alcoholic excess. It has not yet been determined beyond dispute that amblyopia and optic-nerve atrophy may result from alcoholism. A very common result of alcoholism is peripheral neuritis. The effects of tobacco are largely influenced by the personal equation, and are often shown by various functional disorders. Coffee in excess produces insomnia, disorders of special sense, frequent irregular heart action, and muscular tremor. The effects of tea are those produced, in a general way, by overstimulation.

Resolution Concerning the Dispensary Abuse.—Dr. E. D. Ferguson offered the following resolution, which was unanimously adopted:

"*Resolved*, That this association is heartily in sympathy with the efforts being made to correct the hospital and dispensary abuses in the State, and that a committee of five be appointed by the president to represent the association in efforts to be made to correct the said abuses."

Second Day—Wednesday, October 13th.

Stricture of the Rectum.—Dr. W. S. McLaren, of Litchfield, Conn., read this paper. He said that it had been customary to divide rectal strictures into two large classes, viz.: (1) congenital, (2) acquired. We did not see congenital strictures, although in rare instances one observed imperfect development of the anus, but not a true stricture. A stricture in its very nature was acquired. The author divided rectal strictures into malignant and non-malignant strictures. The former were subdivided into (1) traumatic, (2) dysenteric, (3) tuberculous, (4) simple ulcerative, and (5) venereal. Under the head of the causes of traumatic stricture were to be mentioned kicks and blows, operative procedures, and the use of irritating fluids. It must be extremely rarely, if at all, that stricture of the rectum was caused by kicks or blows. In the many cases of dysentery occurring in the army during the late war, not one had a stricture of the rectum; dysentery usually affects the upper part of the bowel. Simple ulceration, if extensive enough to involve the deep layers of the rectum, might cause stricture. Superficial ulcerations were frequently observed to heal without causing any contraction whatever. The venereal division naturally included the great majority of rectal strictures.

Symptomatology: The chief if not the only symptom was obstruction. The "ribbon stool" could not be looked upon as of the slightest diagnostic value, for although commonly found in connection with rectal stricture, it was also an accompaniment of other conditions. One could hardly lay too much stress on the importance of making a digital examination in suspected cases, for the records showed all too frequently that physicians were prone to neglect this very necessary preliminary step to intelligent treatment. In some cases it would be noted that the patient would have a free evacuation at first: then there would be an interval of a few minutes, and another stool. This might be again repeated after another short interval.

Treatment: Bougies should be chosen which easily pass the stricture, and these should be introduced daily and allowed to remain for ten or fifteen minutes. The bowel should be unloaded by mild laxatives and enemata. In performing the radical cure the stricture should be divulsed and a gauze plug inserted in the centre. This prevented hemorrhage and secured good drainage.

Dr. E. D. Ferguson said that the successful treatment of these difficult cases depended very largely upon the thoroughness with which the mucous and muscular coats and the connective tissue around the gut itself were divided. Unless the incision was carried down to normal connective tissue, the cure would not be permanent. The treatment by bougies might possibly effect an occasional cure, but the treatment was protracted and was not entirely devoid of danger.

Pyothorax in Children.—Dr. Douglas Ayres, of Montgomery County, read a paper with this title. He said that statistics showed that pyothorax occurred most frequently during the first five or six years of life, and that the tendency to it diminished rapidly with advancing age. According to a conservative estimate, one-third of all the cases of effusion into the pleural cavity in young children were purulent in character. Among the diseases predisposing to this condition were pneumonia, scarlatina, acute desquamative nephritis, tuberculosis, diphtheria, and whooping-cough. General effusion was the rule, and cystic effusion the exception in infants in whom there was no previous inflammatory action. The speaker directed attention to the very great importance of making frequent and thorough examinations of the chest in children suffering from acute diseases. This was more necessary in infancy than at any other period of life. Owing to the yielding nature of the chest walls in young children, the examiner might often detect fluctuation. The constitutional symptoms varied so greatly in children as to make it unsafe to place much reliance upon them. If fluid were found and it had accumulated very rapidly, especially if there were at the same time an elevation of temperature, it was probable that the fluid was purulent. The degree of temperature, however, was not a sure indication of the character of the effusion. The point could be easily and definitely determined by the use of the aspirating needle. It should be borne in mind that children did not bear delay in operating as well as adults; hence the need in these cases for an early evacuation of the fluid. While statistics seemed to prove that early and repeated aspiration effected many cures, his own experience had been that even after such treatment it had been usually necessary ultimately to make a free incision into the chest. Late operating was more difficult and dangerous, and the chance of effecting a complete and permanent cure was not so good. The incision was preferably made in the sixth intercostal space, under antiseptic precautions. A large single tube would answer in infants under three years of age, but for older children a double tube was better. The tube should be carefully secured by a shield and safety pins. If the pus was not offensive and the temperature not high, irrigation was not indicated and might prove harmful. If the pus was offensive or there were present clots of considerable size, irrigation with boric acid or Labarraque's solution should be employed. This irrigation should be repeated daily

as long as fetor continued or until the discharge became serous.

The author's conclusions were as follows: (1) The time for operation is when the symptoms, verified by exploratory puncture, reveal the presence of pus; (2) the operation of incision and drainage is followed by the best results and early and perfect recovery; (3) aspiration does not remove the pus fully, the treatment is necessarily slow, and it is likely to prove a source of inflammation, necessitating the secondary operation by incision; and (4) incision is followed by a large percentage of recoveries, the drainage is rapid, and leaves no nucleus for future trouble.

Dr. Ferguson said that it had seemed to him that the key to the frequency of empyema in early childhood was to be found in the susceptibility of that period of life to broncho-pneumonitis. We had only to conceive of the involvement of a lobule near the surface of the lung to understand how the inflammatory process might extend to the surface, how the pleural surface might be altered mechanically, and how, as a result, the germs might readily find their way into the pleural cavity.

Report of Some Unusual Cases of Appendicitis.—Dr. Joseph D. Bryant, of New York, read this paper. The first cases cited were examples of a class of chronic appendicitis characterized by an abundant fibrinous exudation. His conclusions regarding this series were: (1) That enormous deposits of lymph may be the only product of disease; (2) though even repeated attacks occur, suppuration is not a common sequel; (3) free incision of the mass and gauze packing were followed by rapid absorption and ultimate cure; (4) suppuration may occur—hence the apendix should be removed; (5) fibrous induration due to chronic appendicitis may be mistaken for sarcoma of the cæcum; and (6) the influence of malaria may stimulate this manifestation of chronic appendicitis. Several miscellaneous cases were then reported. In one, notwithstanding the assertion of the patient that his appendix had already been removed by operation, Dr. Bryant was able to find and remove a complete vermiform appendix, three inches in length. In another case there was an unusually long appendix, extending upward along the outer aspect of the ascending colon; and the unusual extent of the gangrene at the time of the operation showed conclusively that the gangrenous process had existed at the time that he had first seen the case—in other words, when the symptoms and signs had been so mild as to make the surgeon feel justified in postponing operative interference. Another case was cited in illustration of the fact that there might be an early and excessive febrile reaction, without a proportionately severe lesion.

Absence of the Vermiform Appendix.—The last case was that of a young, nervous, and robust woman, who experienced pain on deep pressure over the appendix, but operation was declined. The following year a return of the symptoms made the patient consent to operation. There were at this time a well-marked point of tenderness and a small tumor, revealed by deep pressure. At the operation the most careful scrutiny failed to disclose the least inflammation or the presence of an appendix. According to one observer the appendix was absent only once in two hundred cases. A small tumor was found on the posterior wall of the cæcum, at the usual location of the appendix.

The Surgery of Tuberculosis of the Peritoneum.—Dr. Parkes Weber, of New York, presented a communication on this subject. He said that in a large proportion of cases of tuberculous peritonitis a simple laparotomy would effect a permanent cure. This phenomenon was without an analogue in surgery. The following theories had been advanced to explain it: (1) That it was due to the chemical disinfectants used; (2) that it was to be attributed to drainage; (3) that it was due to the exposure of the abdominal cavity to light and air; (4) that it depended upon the removal of the ascitic fluid; (5) that it resulted from the accidental introduction of bacteria and the production of a toxalbumin which was fatal to the tubercle bacillus; (6) that the operation and attendant handling of the peritoneum constituted a traumatism, and resulted in a fibrinous peritonitis and encapsulation of the bacillus; (7) that the cure was due to the advent of leucocytes and the resulting phagocytic action; and (8) that the mere opening of the abdominal cavity brought about a physiological change in the peritoneum, and consequently rendered the peritoneum an unsuitable soil for the growth of the tubercle bacilli. In a long series of cases in which antiseptics were employed, the percentage of recoveries was slightly higher than in those cases in which no such agents had been used. Again, the patients recovered better without drainage than with it. The last of the theories mentioned was perhaps the most plausible, but even this was but little better than begging the question. Dr. Syms said that in 1890 he had presented a paper in which he expressed the following views, and these he still held: (1) That the danger of the operation was very slight—the mortality being about three per cent.; (2) that sepsis was not so likely to occur in these cases, owing to the pathological changes in the peritoneum; (3) that tuberculous infection of the wound did not occur; (4) that disinfectants were useless and drainage should not be used; (5) that in successful cases the operation did no harm; (6) that established but not advanced pulmonary tuberculosis was an indication for and not against this operation, for it enabled the patient better to withstand the phthisis; and (7) that laparotomy was the proper treatment for these cases. From a pathological standpoint there were three varieties of peritoneal tuberculosis, viz.: (1) the ascitic, (2) the fibrino-plastic, and (3) the caseous or suppurative form. As a matter of fact these represented stages rather than varieties of the disease, and they were frequently associated in the same case. Clinically there were two varieties, viz., those with and those without ascites. The incision should be large enough to allow satisfactory exploration of the abdominal cavity. The ascitic fluid should be evacuated. If there were much granulation tissue with adhesions, the latter should be separated, if this could be done by gentle manipulation. He advised against irrigation or attempted medication of the abdominal cavity. Drainage delayed healing, and this was serious in such cases. Of course, careful attention should be given to the general condition of the patient. Statistics seemed to show that at present the mortality was a little over two per cent., that marked improvement was noted in about eighty per cent., and that permanent cure was effected in about thirty per cent. of all cases operated upon.

Dr. Swan, of Saratoga, said that while at the Johns Hopkins Hospital he had seen about ten cases of tuberculous peritonitis in Dr. Osler's wards, and their course had seemed to confirm the claim made by Dr. Osler that a large number of these cases would go on to recovery without operation: he had also seen in the same hospital twelve cases operated upon by Dr. Howard Kelly, by simple laparotomy and closure of the abdomen without drainage. These patients were all improved before leaving the hospital, but Dr. Kelly claimed that only about fifty per cent. of the patients were "cured"—*i.e.*, remained free from all relapse for a period of five or six years. The speaker then reported a case of tuberculosis confined to the pelvic peritoneum—a very rare condition. At the time of operation several loops of intestine were found

to be adherent by "cystic" peritonitis, and three of these loops were studded with miliary tubercles. The woman promptly recovered from this operation, and he had then opened the main cyst through the vagina, and evacuated about one quart of caseous material.

Dr. H. D. Didama, of Syracuse, asked if Dr. Syms would advise laparotomy in a case in which the diagnosis of tuberculous peritonitis was reasonably clear, even if there was no fluid to be drawn off.

Dr. Syms replied in the affirmative.

Dr. Ely Van de Warker, of Syracuse, said that he believed he had had the honor of introducing this subject into English literature, in a paper read before the American Medical Association in 1883, on "The Cure of Tuberculosis of the Peritoneum by Laparotomy." These cases, he said, bore drainage very badly. Occasionally, when there was pus accumulations beneath the pelvic fascia, drainage through the vaginal roof would be required. The good results from the surgical treatment of tuberculosis of the peritoneum he believed were largely attributable to the free flushing of the cavity.

Dr. Syms closed the discussion. He said that in using the word "cure" in connection with these cases he had adopted Koenig's standard, viz.: that cases going for two years after the operation without a relapse might fairly be looked upon as "cures." According to this criterion, Koenig's cases showed about twenty-four per cent. of cures. In the successful cases the improvement was so rapid and so remarkable that it could not reasonably be explained, as some would have us believe, on the theory of coincidence. In estimating the curability of tuberculosis of the peritoneum without operation, one should give due weight to the fact that in a very large majority of cases it was an utter impossibility to make a positive diagnosis without opening the abdomen.

Tetanus.—Dr. Frederic S. Dennis, of New York, presented a paper on this subject, in which he dwelt particularly on the treatment of tetanus by the antitoxin. He said that it had been proved beyond doubt that tetanus is an infectious disease, caused by the presence of a germ that had been discovered by Nicolaier in 1884. A case had been reported in which this bacillus had gained entrance without an abrasion of any kind. Such an origin might be possible, but certainly the usual mode of entrance was through an abrasion or trifling wound of the skin. The spores of the tetanus bacillus resist death for a long time; they have after eleven years been found alive on a piece of wood taken from the body of a boy who died of tetanus. The toxin of tetanus could be obtained in much the same manner as that of diphtheria. There was, however, an important clinical difference, since the toxin of tetanus was capable of producing all the phenomena of the disease without the pathogenic presence of the tetanus bacilli. The toxin of tetanus is a most virulent poison; it had been estimated that one-three-hundredth grain would kill a human being. It produced its lethal effect very rapidly. The fact that the lesions were located in the nervous system explained the good effects that had been obtained from the administration of chloral and similar drugs. In discussing the treatment, a sharp distinction must be made between acute and chronic tetanus. A study of the effects of the antitoxin enabled him to fix upon the fourteenth day as a point of differentiation between the two varieties of the disease. As a result of his thorough, exhaustive, and scientific study of the subject he felt impelled to state that the facts did not at present warrant the conclusion that in the tetanus antitoxin a remedy existed which would invariably cure tetanus, yet they did show that it was a remedy of the greatest value, particularly in connection with immunization and prevention. The antitoxin of tetanus was obtained from the serum of horses that had been immunized against tetanus by hypodermatic injections of the toxins of the bacillus of tetanus. No animal had ever died from tetanus which had been rendered immune by the tetanus antitoxin before inoculation with the disease. According to Welch, the results were better in proportion to the length of the inoculation period, and that this remedy was of little or no value if this period was less than ten days, or if convulsions had already set in. The prophylactic treatment of tetanus was limited to those cases in which the wound had been inflicted in such a manner as to allow garden earth, or the plaster from walls, or a rusty nail to come in contact with it.

As regards other methods of treatment, statistics proved that chloroform was a very valuable adjuvant, having reduced the death rate ten per cent. in one series of cases. Chloral, given in doses of one hundred to two hundred grains daily, was also very useful, having decreased the mortality six per cent. Indeed, it was because of the evident value of these agents in tetanus that it had been so difficult to judge of the part played by the tetanus antitoxin in those reported cases in which both had been used.

Regarding the prognosis, the speaker said that the mortality was eight times greater in chronic tetanus in those over twenty-five years of age than in those younger than this. The period of incubation was also an important element in the prognosis. He had collected twenty-four cases of tetanus, in twelve of which the duration of the period of incubation was above fourteen days, and in twelve below fourteen days. In the former series there were two deaths, or a mortality of sixteen per cent.; in the latter, there were eleven deaths, or a mortality of ninety-one per cent. Experience had shown that large doses of antitoxin (twenty cubic centimetres or more, three times a day for adults) were necessary, and also that it must be continued for some time. Success was greatly enhanced by proper treatment of the wound. Carbolic acid and bichloride had little influence on the spores unless a little hydrochloric acid was added. A half-per-cent. solution of iodine trichloride was especially potent. As the toxins of tetanus were eliminated chiefly by the kidneys, free diuresis should be established.

In conclusion, Dr. Dennis said that he thought it had been fairly well demonstrated that the mortality in cases of tetanus, treated without the antitoxin, was sixty per cent., as against a death rate of thirty per cent. under the antitoxin treatment.

Dr. B. Cohen, of Buffalo, described the difficulties encountered with the older methods of treatment, and expressed the hope that the serum would soon be accessible to all practitioners.

Dr. Hanan, of Rensselaer County, asked if this antitoxin proved efficacious in tetanus of the newborn.

Dr. Ferguson called attention to the fact that in certain regions the tetanus bacillus was known to be generated more freely in connection with the soil than in others. The prevalence of trismus nascentium in the West Indies was explained by the uncleanly habits of the negro midwives, and the fact that they were brought a good deal in contact with the soil. Where special precautions were taken to avoid infection of the umbilical cord, the number of cases of tetanus had been lessened.

Dr. Dennis, in closing, said that within a few days five cases had been reported in which the antitoxin in small doses had been used in trismus nascentium, with complete success in all of the cases.

Salol and Starch, two parts of the former to one of the latter, are found to be an efficient dressing in specific ulcers.—Schwimmer.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 7, 1897.

EDWARD G. JANEWAY, M.D., PRESIDENT.

Treatment of Puerperal Septic Diseases.—This was the general topic selected for the discussion, which was under the charge of the section on obstetrics and gynæcology.

Medical Treatment; Prophylaxis.—DR. CHARLES JEWETT, of Brooklyn, discussed the medical treatment. He said that for the occurrence of sepsis in childbirth the attending physician must usually hold himself to blame; puerperal sepsis was a preventable disease. Immunity depended chiefly upon the cleanly conduct of the lying-in, but prophylaxis must begin many weeks before labor. Debility, anæmia, syphilis, rheumatism, paludal poisoning, and toxæmias of various forms were all predisposing causes. Retained excrementitious products constituted a very important predisposing factor; hence particular attention should be given to the condition of the kidneys. The origin of puerperal fever was to be found sometimes in the condition of the vagina. The presence of leucorrhœal discharges which were fetid, or which excoriated the skin, should not be overlooked if proper attention were given to recording the history, even without making a direct examination. The streptococcus was frequently associated with gonorrhœal infection. The presence of a pathological secretion called for douching with 1 to 5,000 bichloride solution, followed by a washing out with plain water. Dusting the vaginal surface every two or three days with the subnitrate of bismuth was sometimes beneficial. In the presence of active gonorrhœa, the usual specific treatment for this disease should be carried out. Obstetricians of special training had practically no death rate in private practice, and in time the wealthy lying-in woman might pass through her confinement as safely as her pauper sister in a lying-in institution. Vaginal douching during and after labor in conditions of health was not only unnecessary but injurious. At no time was the liability to infection greater than in the first few hours after the expulsion of the child, for the tissues were in a condition favorable to such a process, and the vitality of the patient was at a low ebb. Manipulations in the passages were especially dangerous at the close of labor, and hence the introduction of the hand into the uterus after labor should not be undertaken lightly.

Curative Local Treatment.—A pelvic exploration should be made as soon as there was reason to suspect infection. This should include a speculum examination of the vagina. Septic vaginal wounds should be cleansed once or twice daily, and touched with carbolic acid or chloride-of-zinc solution. A strip of iodoform gauze should then be left in the vagina to keep the walls apart. Vaginal douching was useful in the presence of foul discharges. An antiseptic was more efficacious than a plain injection, and to a mild, non-toxic antiseptic there could be no objection. Such an agent was to be found in peroxide of hydrogen, or a one-to-ten Labarraque's solution. Douches should be given only by the physician, and with the greatest care. No active interference within the uterus should be undertaken until the physician was assured that it was involved in the septic process. A gaping cervix and a foul discharge were presumptive evidence of such a condition.

Curettage.—To the trained hand the dull curette was almost as satisfactory as the finger for examination of the interior of the uterus, and was decidedly safer, and with it small shreds of secundines could be removed without injury to the endometrium. A few drops of the lochia might also be obtained for bacteriological examination. If the membranes were retained, curetting should be done at once. It had been objected that a sharp curette laid open sinuses and dislodged thrombi, but as the same result followed the use of the dull curette, and the latter was not so efficient an instrument, the writer preferred the sharp instrument. The uterus should next be washed out with a proper antiseptic. The empirical and routine use of the curette had done harm. The extension of the infection to the parametrium did not, in his opinion, preclude the use of the curette—it rather emphasized the need for its immediate employment. The endometrium might be painted with the tincture of iodine, or with a fifty-per-cent. carbolic-acid solution, the uterus having first been washed out with salt solution. Finally, a loose packing of iodoform gauze should be left in the cavity. He suspected that the chief benefit from the iodoform gauze was due to the iodoform, and not to the gauze, and acting upon this idea he had repeatedly used with satisfaction iodoform pencils instead of the gauze. Intra-uterine irrigation was chiefly of value to wash away dead animal matter lying free in the uterine cavity, and as its action was chiefly mechanical many obstetricians preferred sterilized water to active antiseptic solutions. Tarnier advised iodine water. Frequent douching was decidedly injurious.

Systemic Treatment.—The speaker said that general measures were indicated to combat the constitutional effects of the poison as well as to control the local process. Alcoholic stimulants, tonics, eliminants, and proper alimentation must be our main reliance. Alcohol should be given to the point of intoxication, the maximum daily dose being a quart of brandy or its equivalent. Frequently, however, this dosage must be reduced, owing to the intolerance of the stomach. Strychnine and quinine were useful as tonics, especially the former, given in doses of one-thirtieth of a grain, three or six times a day. Quinine was of value in doses of three or four grains every six or eight hours; in larger doses it was injurious by hindering oxidation. The diet should consist only of liquid food, given at short intervals. All measures tending to promote elimination should be employed. To this end it was important that the patient should be made to drink large quantities of pure water, or of alkaline waters. The judicious employment of saline purgatives also had a rational therapeutic basis as eliminants. To limit the diffusion of the poison from the primary focus, it had been suggested by some to use ergot. As the coal-tar products were not only cardiac depressants but hindered elimination, they should be very sparingly used; on the other hand, cold bathing increased oxidation and favored elimination.

Serum Treatment Unsatisfactory.—The statistics of the serum treatment of puerperal sepsis were thus far unsatisfactory. His own experience had been limited to six cases; in only one was any improvement noted, and this was temporary, and possibly not due to the serum. In but few instances had injurious effects been observed, but there was still some reason for believing that this treatment was not entirely free from danger. The dose varied from ten to one hundred and twenty cubic centimetres daily, the serum being injected subcutaneously under aseptic precautions. Certain inoculation experiments would seem to show that the serum had no protective power whatever, and hence it was not probable that it possessed any curative power. Nuclein had been recently employed in puerperal sepsis, and some observers had expressed the opinion that it was better than the antistreptococcus serum. He had personally used it in only three cases, and no definite results had been obtained in

these. He used doses of thirty minims, given subcutaneously at intervals of four hours.

The Surgical Treatment.—Dr. Egbert H. Grandin discussed this phase of the subject. He said that the general adoption of the view that puerperal infection was simply wound infection had greatly simplified the study of the subject, and had led to the adoption of well-known general surgical principles for treatment. To-day it was believed that puerperal infection was dependent either upon toxins or a pathogenic infection. When the condition was due to non-pathogenic germs, it was called "sapræmia;" when due to pathogenic microbes, "septicæmia." In the former the elements of putrefaction tended to remain localized at the site of their origin, and for this reason sapræmia, treated early and properly, could usually be controlled. Septicæmia, on the other hand, depended upon the rapid multiplication of pathogenic germs, so that the surgeon must deal not only with local but with systemic infection. A sapræmia by improper or delayed local treatment might pass into puerperal septicæmia.

Indications for Curettage.—The commonest form was sapræmia, and the surgical measure in vogue for its control was curettage. He was satisfied that this procedure was resorted to unneccessarily, and often to the detriment of the patient. He had himself been a culprit in this matter, and so could speak with the positiveness born of personal experience. In sapræmic endometritis the curette was a valuable instrument, but in the case of endometritis due to the presence of pathogenic microbes resort to the curette caused a dissemination of these microbes throughout the body. The careful researches of German investigators showed that underlying the putrescent mass in the uterus was a granulation bed of leucocytes, which opposed a barrier to the microbes endeavoring to gain entrance to the system. If this barrier were broken down by the curette, the local infection would be made a general one. The object of treatment of puerperal septic conditions should be to favor local conditions, and when operation was demanded it should be done before the occurrence of systemic infection. There were two varieties of puerperal endometritis—the putrid and the septic. In the former, a granulation barrier formed; in the latter, if the barrier were present at all, it was extremely thin. Putrid endometritis at the present time usually became septic only when there was some fault in the technique at the time of delivery or during the puerperium. It was, therefore, possible in the majority of cases to differentiate the form of endometritis present. This differentiation was accomplished by exploring the uterine cavity with the fingers, under an anæsthetic, prior to a resort to the curette. If secundines or débris were found to be retained, the curette should be used; if these were not found, then the curette was contraindicated. The curette should remove only the putrid mass, and the instrument should work down only to the granulation layer. The uterine cavity was next to be irrigated freely, and filled with sterile gauze, not with the idea of drainage but rather with the object of keeping the cavity open for further inspection or treatment, should this be required. He favored the removal of the gauze in most cases after thirty-six hours.

Iodoform Gauze Packing Dangerous and Misleading.—Dr. Grandin rejected iodoform gauze for the reason that not infrequently it caused iodoform toxæmia, which aggravated the symptoms already present, and often misled the physician into believing that the disease was passing into the graver or septic form. In the septic variety of endometritis the examination of the interior of the uterus under anæsthesia and perfect asepsis would not reveal retained membranes. As a rule, in the septic form the less the physician resorted to active measures the better; his aim should be to kill the germs, if possible, while active only in the uterus. He preferred to give one intra-uterine irrigation, and then pack with gauze wetted with absolute alcohol. The surgical treatment applicable after the uterus, tubes, ovaries, and peritoneum had become involved, consisted in their removal. The technique of the operation was the same in diseases of the appendages when the seat of puerperal sepsis as when this factor did not appear. There was, however, a vast difference in the symptomatology and prognosis following the operation. This difference might be best described as due to a "puerperal" influence. When there were local peritonitis, salpingitis, etc., and the symptomatology became more grave, it was probable that the plastic peritonitis or cellulitis was becoming purulent, and if expectant treatment were continued general infection might ensue, or the process might extend and end fatally in a general septic peritonitis. The patient should be anæsthetized, the location of the purulent foci determined, and then these should be evacuated and drained. In reality, this suppurative process at the beginning was extraperitoneal. When local peritonitis was associated with, or merged into a metritis, early recognition and very radical surgery were necessary to save life. The speaker said that although he had read many reports of apparently desperate cases that had terminated in recovery under treatment by hysterectomy, he had never been convinced of the wisdom of this method. The difficulty in deciding was owing to the fact that the clinical picture which would seem to demand hysterectomy had over and over again proved fallacious. For this reason he favored the surgical treatment of each complicating factor as it arose, in the hope that the patient could be tided over the acute stage, and the case would progress to a symptomatic cure, or that conclusive evidence of the necessity for hysterectomy would be forthcoming.

General Septic Puerperal Peritonitis.—General septic peritonitis, he said, might well be termed the *bête noir* of the surgeon, and particularly when it complicated the puerperal state. He did not believe that a well-authenticated instance of the successful use of the streptococcus serum in general septic puerperal peritonitis had been reported. As a rule, general septic peritonitis was consecutive to puerperal metritis, or a perforation of septic pus into the cavity. In these cases systemic infection was very rapid, and the best that surgery could offer was multiple incision, free irrigation, and, if found effective, the removal of the uterus, tubes, and ovaries. The exudative or plastic type of peritonitis was more frequently met with at the present time, and this was the variety of peritonitis which formerly was successfully treated with enormous doses of opium—that drug which to-day had an important place in the treatment of the same condition. When the exudative type went on to the formation of pockets of pus, the best the surgeon could do was to open them and drain, remembering that whenever possible he should drain in nature's way—*i.e.*, downward.

Serum Treatment Inefficient and Not without Danger.—Dr. C. P. Noble, of Philadelphia, opened the general discussion. He said that the serum treatment of puerperal sepsis had not been very satisfactory in Philadelphia. In that city an evening had been devoted to a consideration of the subject, and twelve cases had been reported. Of the twelve patients, six recovered. It was believed that in six the treatment did no good, that in two it was distinctly harmful, and that in four it proved useful. Inquiry seemed to show that since that time like results had been obtained. Undoubtedly the very high mortality in these cases was to be explained by the fact that the serum treatment had been used in exceptionally severe cases.

Personally he would not feel inclined to use this treatment unless the bacteriological examination showed distinctly that the sepsis was due to the presence of streptococci; under other circumstances such treatment seemed to him irrational.

Vaginal Lesions a Common Source of Infection.—He agreed most heartily with Dr. Grandin regarding the great importance of making an accurate differential diagnosis at the outset. He would not only make the examination under an anæsthetic, but he would look very carefully into the condition of the vagina as well as the uterus. It was not at all uncommon for the infection to be due to lesions in the vagina, and under such circumstances if the vaginal lesions were touched with pure carbolic acid it was improbable that the septic process would extend. In cases seen at a later stage, this examination and treatment might be of service as a means of differentiation.

A Plea for Conservative Surgery.—His experience had been that in puerperal infection the patient was much more likely to recover with intact pelvic organs than when the infection was non-puerperal. For this reason we should be slow to do radical operations in puerperal cases. He had had a number of cases in which there had been extensive pelvic exudates, and yet by ordinary surgical measures recovery had been effected, and the woman had subsequently become pregnant. He cited one case in which there had been very extensive agglutination of the tissues, and yet some time afterward, having occasion to operate for a hernia, he had had an opportunity of inspecting the abdomen and pelvis. He had been greatly surprised at that time to note that only one small pelvic adhesion remained. The speaker advocated drainage operations in puerperal cases, resorting if need be subsequently to a more radical procedure, such as the removal of a tube. If the radical operation were done in the first instance, the surgeon would often feel called upon to remove organs which later on, owing to changed conditions, he would not feel justified in extirpating. Regarding irrigations, he said that if they did not limit and control the puerperal sepsis in one or two days, they should not be persisted in for a longer time. His experience with intravenous injections of salt solution had been particularly favorable.

Good Results from the Serum.—Dr. Paul F. Mundé said that he had been exceedingly gratified at the conservative position taken by the readers of the papers regarding surgical measures. His practice had been to trust largely to stimulants and good feeding to bring about the recovery of cases of puerperal septicæmia in which no retained septic matter was found in the vagina or uterus. He had had two very successful cases in which the streptococcic serum had been used, yet he would not say that the patients had recovered because of the use of the serum. In such a desperate condition one would clutch at almost anything, and for the present at least he would be willing to employ it. The speaker said that in 1883 he had read a paper on the use of antipyrin in puerperal septicæmia. At that time it had seemed to be the one useful agent, as it effectively reduced the temperature and to this extent prevented exhaustion. Phenactin had taken its place in his practice, but it was a very poor substitute.

Use of the Curette.—He had changed his views regarding curettage. When there was no septic product to be removed from the uterus, and there was simply a septic endometritis, no matter how thick the mucous membrane might be, the curette should not be used, for under these circumstances it would serve only to promote general septic infection. The treatment of the results of puerperal septicæmia should be carried out on the old surgical principle of evacuating pus wherever found. By the time the uterus had become so infected as to make it seem necessary to extirpate it, he was of the opinion that no known measure—hysterectomy or any other—would save that patient's life. When there was a purulent peritonitis, whether puerperal or not, he believed the abdomen should be opened freely, and, if necessary, drainage established from below. The results were not good, but occasionally a patient recovered under such treatment; whereas without such surgical interference all the patients died.

Dr. Henry C. Coe recalled one case in which he had curetted a sloughing uterus, and within two hours the patient had died of pulmonary embolism. He was in accord with the view held by the late Dr. Lusk, that we should not curette or stir up a sloughing uterus. It was not possible, he thought, to make the differential diagnosis in these cases of puerperal sepsis without giving an anæsthetic and examining the interior of the uterus very carefully with the finger or curette; even then it was difficult.

Anteflexion a Common Cause of Imperfect Drainage.—He believed that imperfect drainage of the uterus, due to anteflexion, was a more common cause of puerperal sepsis than was generally conceded. He was inclined to favor in these cases the use of irrigations with peroxide of hydrogen, as he had never seen any harm from its use and had observed a great deal of good from it.

Oxygen and Saline Injections Useful.—He had found the intravenous use of saline solution beneficial in some desperate cases of puerperal sepsis. In some cases he had used oxygen inhalations for weeks at a time, and with exceedingly gratifying results. So far as he had tried Dr. Ill's method of packing the uterus with gauze and keeping it moist for several days with forty-per-cent. alcohol, he had been favorably impressed with it. He had been looking for a suitable case for hysterectomy, but so far had not met with one in which this procedure seemed to him justifiable. The operation for general septic peritonitis was an almost hopeless one.

Dr. C. A. Von Ramdohr said that his views, based on personal experience, could be briefly summarized as follows: (1) Never use bichloride, for it had been proved again and again that under certain circumstances, when used in the genital puerperal canal, even in dilute solution (1 to 5,000 or 10,000), it would give rise to nephritis. (2) Wherever there was a sapræmia, as indicated by fever, foul lochia, open os, the presence of retained membranes, etc., remove the cause and give one thorough intra-uterine douche. Gauze drainage was optional. (3) Whenever there was a pus collection, it should be treated like any other abscess. (4) If extensive peri-uterine abscesses were present and the uterus proved an obstacle to drainage, this organ should be removed, because it would eventually prove a nidus for disease, and the organ would never again be able to fulfil its special mission. (5) Whenever there was septicæmia present, indicated only by the temperature and pulse, and without local signs or symptoms, we should combat the multiplication of the cocci, the high temperature, and the resulting heart weakness. For this purpose, alcohol in large doses and hydrotherapeutics seemed to have given the best results. (6) The use of the coal-tar products as antipyretics constituted a step backward. (7) Local treatment, when systemic infection had taken place, was worse than useless.

Puerperal Sepsis Successfully Controlled by Hysterectomy.—Dr. H. N. Vineberg referred to a recent case of puerperal sepsis in which he had operated. The patient, Mrs. F——, eighteen years of age, was delivered of her first child on May 31st. Her physician had informed him that the labor had been easy and normal, and that the placenta had come away entire. A chill and fever occurred on the sixth day.

and when first seen by him, two days later, the temperature was 103° F., the pulse was 120, soft and compressible, and she was slightly delirious. Examination showed the perineum intact, the labia majora quite œdematous, no vaginal discharge or fetor, the cervix but slightly lacerated, and the canal well closed. The uterus was large and not specially sensitive to pressure, and the adnexa were free from exudate. A diagnosis of septic endometritis was made, and curettage and repeated irrigations were advised. With a sharp curette he had removed considerable grayish-white tissue, and had then irrigated the uterus with bichloride, 1 to 3,000, followed by salt water. Three days later, June 11th, he was again sent for, and learned that owing to the miserable surroundings of the patient his directions had not been carried out. There had been only temporary improvement after the curettage. Her condition at this time was very bad, and she was removed to St. Mark's Hospital in the evening. She was given an intra-uterine douche, but nothing came away. By the evening of June 12th her condition had become so bad that he had performed total abdominal hysterectomy. The broad ligaments were quite œdematous, but the adnexa were apparently normal. At the close of the operation her pulse was fully as good as it had been at the beginning. For the next three or four days the temperature continued to be high, owing to the suppuration in the portions of the broad ligament remaining behind. Drainage was then established through the vagina. The patient eventually made a good recovery. On opening the uterus after its removal, a large portion of retained placenta was found, which had become organized. It filled the left horn and occupied most of the anterior wall of the uterus. It was particularly fetid, and although the uterus had been irrigated a short time before the interior was covered with mucus. He was inclined to think that if the cervical canal had been dilated and the uterus subjected to constant irrigation, the patient might have recovered without such a radical operation.

Use of Ergot an Important Safeguard.—Dr. Robert A. Murray said he thought septic cases were often met with because the old rule about the use of ergot had been neglected. In a very large outdoor obstetric experience, at one time amid the most miserable surroundings, he had not had a single septic case, and he attributed this to the use of carbolic acid and glycerin as the lubricant for the examining finger, and to the administration of ergot to insure good uterine contraction after delivery. This prevented the formation and retention of blood clots in the uterus. If there were the slightest rise of temperature, the interior of the uterus should be systematically and minutely explored with the finger. If on the withdrawal of the finger the physician perceived a foul odor, he should take this as an indication that the uterus demanded local treatment. The best local treatment in his opinion was by the curette, followed by a swabbing out with tincture of iodine, alcohol, or carbolic acid. He knew of no drug so efficacious in the control of the fever as veratrum viride, given in small doses at short intervals until the pulse became slow. If it proved too depressing, alcohol would always be found an excellent antidote. He had yet to see at autopsy a case of diffuse peritonitis that had led him to think that anything could have been done surgically to save the patient's life. He agreed with Dr. Grandin as to the advisability of draining in the extremely localized cases, and postponing more radical measures.

Dr. J. Riddle Goffe said that he preferred to explore the interior of the uterus in these cases with the curette rather than with the finger, as there seemed to him less danger of sepsis from such a mode of examination. He had kept careful records during the past six years of the cause of sepsis in the cases that he had seen in consultation, and in every instance the hand had been carried into the uterus.

Unfavorable Experience with the Antistreptococcic Serum.—Dr. S. Marx said that Dr. Grandin had clearly stated the limitations of the curette, but had neglected to say how the operator was to know when he had reached that "granulation barrier." The serum treatment had been found successful in ordinary surgical cases, but not in puerperal ones. This was probably due partly to the modifying influence of the puerperium, and partly to the occurrence of mixed infection and the difficulty of removing the source of the infection. In a large number of cases reported as cured by the serum, the condition had been a sapræmia, and not a true septicæmia. He had had five cases in which the serum had been used. In the first case a bacteriological examination showed the streptococcus and the colon bacillus. In that case there was an antepartum infection, and although the serum was used early the patient died very quickly. In the second case nothing but the streptococcus was found by the bacteriologist. Fresh Marmorek's serum was used, notwithstanding the apparently fair condition of the patient, yet she died within five hours, and apparently as a result of the injection of the serum. In the third case the woman developed an acute endocarditis, an embolism of the lung, and diffuse emboli of the skin. She died quite suddenly at the end of the second week from pulmonary embolism. In the fourth case a bacteriological examination showed streptococci, and the patient died at the end of a week. In the fifth case no bacteriological examination had been made. Instead of the usual fall of temperature after the use of the serum, in this case the temperature rose.

Dr. J. Milton Mabbott called attention to the important aid to diagnosis sometimes afforded by quinine or by an examination of the blood for the malarial plasmodium. In this way some fevers might be explained which otherwise the attending physician might be led to attribute to sepsis.

The Method of Intra-Uterine Irrigation.—Dr. W. Evelyn Porter said that but little had been said about the method of employing the intra-uterine irrigation treatment. Undoubtedly the frequent introduction of the Chamberlin tube would give rise to much discomfort and exhaustion, but if a flexible sterilized catheter were introduced well up to the fundus and left in place, a rubber drainage tube being attached to it and brought out of the vulva, frequent irrigation could be employed with most excellent results. When a retained portion of placenta could be located with the finger, the placental forceps would be found very much better than either the blunt or the sharp curette.

Dr. A. M. Lesser cited a case in which the malarial origin of the fever had been clearly proved by the results of treatment with quinine. In his experience it had not been necessary to use such large doses of alcohol as had been recommended this evening. During the period of high fever his patients were given water and but little food: when the temperature was lower more nourishing food was administered. He favored the use of gauze in the uterus, kept moist with alcohol.

Dr. Jewett said that he did not think the distinction between sapræmia and sepsis was so sharp or so important as many were inclined to believe. He would use the curette in every case in which the uterus contained decomposing clots, necrotic shreds of membrane, or fragments of placenta. He had been struck with the frequency with which malarial poisoning was combined with sepsis.

Dr. Grandin, in closing the discussion, took exception to the statement made by one speaker that the curette was preferable to the finger in exploring the uter-

ine cavity. When the retained portion of secundines had been removed by the curette, it would be found that the instrument had reached down to the "granulation layer."

Clinical Department.

SOME PRACTICAL POINTS GATHERED FROM SOURCES WISE AND OTHERWISE.[1]

By WILL B. DAVIS, M.D.,

PUEBLO, COLO.

Once upon a time a Texas cowboy gave me a remedy for that disease of as many names as the many dermatologists who have tried to investigate it have seen proper to call it—most commonly known as prairie or winter itch. The remedy was a saturated solution of bichloride of mercury in alcohol, about one hundred and sixty grains to the ounce. I use it in the strength of from thirty to sixty grains to the ounce. My method of applying it is lightly to sponge a surface of about three inches square at a time, selecting a different site for each successive sponging, repeating the procedure morning and evening; and if prompt relief is not obtained, sponging over a larger and larger extent, until a surface of six inches square is attained. Usually in three or four days a complete and permanent cure is effected—long before one-tenth of the body surface has been gone over.

In selecting the sites for making the appplications, those most affected are to be preferred, if for no other reason than that the itching immediately where the remedy is applied is instantly relieved, which indeed is a great temptation to the sufferer to push the treatment too far. It does not blister or cause any inconvenience, and in the many cases in which I have thus used the treatment there was no constitutional disturbance.

The fact that the disease was permanently cured when a comparatively small surface of the body had been sponged, satisfied my mind that its action was not altogether local; yet in giving the bichloride internally in as large doses as I dared it seemed to have no effect upon the itch. Perhaps the dermatologist can explain this. I only know that the remedy as given is a quick and certain specific. To be sure, it must be given with caution, and its dangers fully explained if it is committed to the hands of a patient. The fault in any untoward result would not be with the remedy, but in its careless or reckless use; for at a modest estimate I have used it in at least one hundred cases, and know from personal observation the entire correctness of the foregoing statements.

Some sixteen years ago a barber gave me a remedy for ringworm. It was a saturated solution of salicylic acid in alcohol—about two and one-half drachms to the ounce. It can be applied with a hair pencil, or sponged over the surface before retiring at night. The alcohol soon evaporates, leaving a deposit of salicylic acid in the form of a white film or powder, which can be readily washed off when desired. One application will suffice. In a few days the epithelium over the affected surface peels off, and in a week or ten days the parts return to their normal appearance. Nothing could be more elegant or satisfactory.

We all know that salicylic acid is held in high esteem by our dermatologists now, especially in skin diseases accompanied with pruritus, but had I waited for my cue from these sources I would have been several years later in adopting it. All I could learn of the barber's information who gave it to me was that he learned it from another barber.

[1] Read before the Colorado State Medical Society, at Denver, June 16, 1897.

Scarcely a year or six months have passed since I joined the ranks of the profession but the files of the medical journals have indicated some remedy for obstinate hiccough. But somewhere in the early eighties I read in the Medical Record a common-sense remedy—one which I found to succeed in one case of nearly seventy-two hours' duration, after all customary medicinal remedies had failed, and I have successfully tried it in several cases since. It was to make pressure against the diaphragm. Pressure upon an affected muscle will readily relieve local spasm anywhere, for a time at least, as in blepharospasm, itself sometimes annoying, which pressure upon the orbicularis palpebrarum will check.

The causes of local spasms are sometimes very remote, and when ascertainable may or may not be readily relieved; but hiccough is sometimes so distressing and persistent that it is a satisfaction to be able to relieve it even temporarily, or until from some imprudence or a fit of coughing the spasms are renewed, when again the same remedy may be used with effect. The technical application consists in the operator sitting on a firm table, placing one knee on the spine of the patient, and, with both hands reaching around either side, pressing his fingers well up under the ribs to the right and left of the epigastric region, the patient at the same time inclining forward, thus relaxing the abdominal muscles and facilitating the effort to make pressure upon the diaphragm. When the hiccough is checked, which is usually at once, and the operator tires of maintaining his position, the pressure should be so gradually relaxed that the patient would scarcely know when the hands were removed.

The patient could also be taught how to make pressure himself on his diaphragm, in the event hiccough should return, by pressing his fingers up under the ribs as did the operator, and assuming a position to relax completely the abdominal muscles which would be self-suggestive, whether lying, sitting, or standing.

For chronic constipation, from which so many of the human family suffer, I wish most heartily to indorse and recommend thorough divulsion of the rectum. So universal has been the relief from chronic constipation following all my rectal operations in which divulsion was required that I have recommended divulsion in many such cases and have succeeded in inducing some to submit to the treatment, with complete cures in all that did. Just how the cure comes about it is not the purpose of this paper to discuss. I simply commend divulsion as the best and only permanent cure known to me. In the train of chronic constipation there may be many other incidental troubles which also are thereby relieved, and this fact alone accounts for many of the so-called wonderful cures by the orificial surgeon.

I believe that advocacy of this treatment and its adoption by the profession would do more than any one thing to bankrupt the patent-medicine traffic in this country. The main difficulty in its application is to induce the patient to undergo anæsthesia and remain in bed a few days—say five or six. The dangers of the procedure pertain only to the use of an anæsthetic, which all can estimate for themselves. For my own part, I will say that having been a lifelong sufferer from chronic constipation and later from piles, and having submitted to the treatment myself and having since enjoyed such luxurious relief from constipation and its attendant ills, I count the possible dangers from anæsthesia as nothing compared to the immensity of the gain to be obtained.

In doing the operation, to secure full and permanent benefit it should be done thoroughly and well. That is to say, the divulsion should be thorough, from muco-cutaneous fold to rectal ampulla. Every resisting fibre should be completely paralyzed, according to

the methods described in the books. This will require general anæsthesia, for local anæsthetics will not avail.

On the subject of appendicitis I beg to refer to one point only—that is, to the license which some surgeons take, on the strength of the good advice of McBurney, Morris, and others, not to search too persistently for the appendix, as well as not to run too great a risk of breaking through the peritoneal barricade to remove it radically when found. That such advice was not intended to warrant the opening of an appendical abscess and packing with gauze as a routine course is clear enough. Such men neither do that kind of work nor advise it.

I am led to speak of this on account of the large proportion of cases, in the few operations I have done, which had been thus dealt with formerly. I could not but feel that had reasonable intelligence been exercised at the first operations, such patients would not have been subjected to further attacks or operations. I have been strongly impressed more than once that neither valor nor its better part, discretion, had had a fair show.

HERNIA IN AN INFANT TEN WEEKS OF AGE.

By S. H. CHAMPLIN, M.D.,

CHICAGO, ILL.

In the MEDICAL RECORD of June 12th there is an extract from an article by Dowd,[1] on "Strangulated Hernia in an Infant Four Months Old." On June 27th and previous to reading the above, I was called to see an infant, ten weeks old, which was said by the mother to be suffering from suppression of urine. The mother said the child had a severe paroxysm of coughing at four o'clock that morning, and had cried continuously up to the time of my visit, at 2 P.M., and had not passed urine during the interval.

On examination a small tumor on the right side, about as large as the end of a man's thumb, was found extending through the external abdominal ring into the upper part of the scrotum, the testicles were in their normal position. Previous to that morning the child had shown no evidence of rupture.

Suggesting the possibility of operation to the parents, I told them that taxis would first be attempted. For thirty minutes very careful manipulations were tried, with the child in different positions, without success.

Finally I placed the baby's head and shoulders on my right knee and the buttocks on my left knee at a somewhat higher level than the right, and instructed the mother to hold down the feet, thus putting the abdominal wall on the stretch. After about one minute of delicate manipulation in this position, the bowel was reduced with an audible gurgle; and immediately following the reduction the baby passed about two ounces of clear straw-colored urine. Five minutes later the child was sound asleep.

July 7th I saw the baby again; there had been no return of the hernia, and the little one seemed none the worse for its rather severe experience.

I do not wish to appear as an advocate of prolonged taxis, especially in children; but the parents in this case strenuously objected to an operation, and I had no choice in the matter. However, I advised operation in case there was a reappearance of the hernia.

1,002 MADISON STREET.

Incise and disinfect at once, instead of waiting for suppuration to occur in infected wounds.—*International Journal of Surgery.*

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE MEDICAL COUNCIL ELECTION—A NEWSPAPER ON ABUSE OF MEDICAL CHARITIES—"OUIDA" ON CRUELTY—MEDICAL RETICENCE—CYCLE ACCIDENT TO A DOCTOR—HEALTH OF MR. E. HART—SIR S. WILKS—EPIDEMIC OF TYPHOID—DEATHS OF DRS. FLETCHER AND RYE—DIPHTHERIA.

LONDON, September 24, 1897.

The election of a direct representative to the Medical Council, which I announced as imminent last week, presents curious perplexities. Dr. Rentoul's resignation necessitated the election. On Monday it was announced that he had withdrawn his resignation in a letter to the president dated the 18th. This letter was referred to the legal advisers of the council, who pronounce the resignation inoperative. So the election proceeds. Another candidate has come forward in the person of James Arthur Rigby, M.D., of the London University, etc. In a long address he gives some account of his thirty-three years' experience and the views he advances. He is a strong advocate of the claims of the general practitioners, and takes almost a trades-union view of their rights. He laments that "the old-fashioned consulting physician is rapidly becoming a thing of the past and is being superseded by the modern specialist." To the latter he scarcely accords justice, but this may perhaps be excused in an election address. If we are to have specialists at all, he would have them attain their position through examinations and diplomas for the dignity, such as have been inaugurated in the public-health service. Few people, however, whom I have met consider the public-health diplomas a blessing save to the corporations and individuals that finger the fees. This item in his programme is far less taking than his denunciation of medical-aid societies, prescribing chemists, advertising quacks, and the newspapers which sell their columns to the worst impostors. In a summary he announces first of all, that he will "try and suppress all mischievous, lying, and filthy advertisements which disfigure what should be a respectable press." If sending Dr. Rigby to the council would be likely to accomplish this one of his proposed reforms, he might reckon on his return by an overwhelming majority.

Dr. Dolan, of Halifax, is another candidate, as he was at the last election. He stands as a general practitioner, and says he is willing to give way to any such who may be more widely supported, but not to a consultant like Mr. Horsley. This cry that representation was given to the general practitioners as such is inaccurate. They are not recognized as a distinct class in the act. It is registered practitioners who have a vote, and of course consultants of all kinds are registered. It is true the generals are in an overwhelming majority and can carry any election, but it is quite possible a consultant may be a model representative of their interests, and Mr. Horsley's work on the Defence Union has produced the widespread impression that he is such a one. He addressed an influential meeting of the profession at Manchester on Tuesday, and was assured of the almost unanimous support of those present.

The rumor that Sir W. Foster might come forward is confirmed, I regret to say. He had his day in the council, and, though it is the cue of the wire-pullers in the British Medical Association to extol him and his own cue to talk of "our great association," it is difficult to see what he achieved. He could have kept the seat when he had it, but having left it should be content to see it occupied by some one else. The council will be all the better for new blood.

The *Globe* came out last Monday with an editorial note on the abuse of dispensaries and hospitals, which is gratifying to medical reformers. It is refreshing to find one of our best-conducted newspapers denouncing "the exceedingly mean people who, without the excuse of poverty, victimize" medical charities, and urging subscribers "to exercise all possible care in complying with requests for letters of recommendation."

Here the *Globe* hits the nail on the head, for it is undoubtedly a fact that very few subscribers consider it a duty to make any inquiry about an applicant for a letter. Many, indeed, look upon their subscription as purchasing so many letters to distribute among their dependants as a cheap charity.

"Ouida" has been denouncing in vigorous terms the slaughter of birds which goes on in Italy and to some extent in England too. Quite recently some rare birds were shot as soon as they appeared here. Every one will agree with "Ouida" so far, but she unfortunately joins to her denunciation equal condemnation of dog muzzles and Pasteurism, and declares that if the public does not close the laboratories "the whole human race will be blood poisoned." She adds: "The danger is clearly enough recognized by those who are not the dupes of scientists. I think the domination of these empirics is the greatest calamity that has ever befallen mankind." "Ouida" in her tantrums is less amusing than at other times, and the scientists will survive her anger.

The responsibilities of practitioners as to the observance of reticence about patients seem to increase, and juries are taking a severe view of remarks affecting the friends or guardians of the sick. A case of libel was tried on Saturday against a parish doctor, who, in defending himself against a charge of neglecting a child with diphtheria, wrote to the board of guardians that the neglect was on the parents' side in not calling in a doctor earlier. He added that the child's life was insured, and that when the mother came for the certificate of death she was intoxicated. His letter was read to the board and an action was brought. The jury found for the parents and assessed the damages at £200, but notice of appeal was given on the ground that the amount was excessive. The judge advised the parents to accept much less, said half would have been sufficient, and the case was adjourned. Unless substantial reduction is made, the judge promised to grant a new trial.

Mr. R. J. Stephens, M.R.C.S., met his death from a bicycle accident on the 11th inst. He was riding down a hill with his feet on the rest, in company with professional friends, when the cycle suddenly swerved and he fell on his head. He died the same night, without having recovered consciousness, from cerebral hemorrhage of considerable extent. He was only thirty-four years old.

Mr. Ernest Hart, whose indifferent health was well known in certain circles, has had to undergo a serious operation, amputation of the leg, for necrosis of bone in the foot supervening on ulceration, probably connected with the glycosuria of which he was the subject. The operation was well borne, and I hear to-day that he is convalescent from it.

The old pupils and friends of Sir S. Wilks propose to entertain him at a dinner.

A serious outbreak of typhoid has occurred at Maidstone, Kent. More than three hundred cases have been notified.

Dr. Adam Fletcher, of Bury, where he had practised for nearly half a century, died on the 28th ult. He was a justice of the peace and greatly respected.

Mr. Brisley Rye died on the 1st inst. He had for some years retired. He was born in 1812, and took his M.R.C.S. in 1836.

The deaths registered last week from diphtheria numbered thirty-five, being ten in excess of the preceding week, but six below the corrected decennial average. In reference to this disease, Dr. F. J. Allan, the able medical officer of health of the Strand district, remarks in his report that in the first nine weeks of the quarter the number of cases notified in London had been two hundred and fifty-nine per week, the number for the corresponding week of last year having been two hundred and sixty-four. So far the cases notified were under the number of the same period of 1896. He thinks the reason why considerable alarm has been expressed is that the asylums board has not in its hospitals sufficient accommodation for the increasing class of patients who are ready to resort to them. Within the next two months the disease reaches its usual maximum, and from present appearances Dr. Allan does not consider it probable that there will be so many cases as last year.

THE PREVENTION OF UTERINE DISPLACEMENTS.

[illegible]

SIR: Permit me to correct a remark attributed to me in your report of the discussion on Dr. Savidge's paper on "Retrodeviations of the Uterus," in last week's MEDICAL RECORD. I did not say that I had for many years recommended "that every parturient woman should have a pessary introduced before she was allowed to get out of bed" "as a prevention of subinvolution." That would be an unnecessary and very useless practice, and decidedly "meddlesome gynæcology." What I did say was that I had for many years advised the introduction of a pessary as a cure for an old retrodisplacement of the uterus before a parturient woman so afflicted was allowed to leave her bed, at the time when all her pelvic organs were undergoing involution. That is quite a different thing from inserting a pessary into every puerpera as a prevention of a possible subsequent displacement or the occurrence of subinvolution.

PAUL F. MUNDÉ, M.D.

[illegible]

New Instruments.

A NEW SEPTUM KNIFE.

BY JOSEPH E. [illegible], M.D.,

[illegible]

[illegible]

THE accompanying illustration represents a new instrument which I have devised and used with great satisfaction in removing cartilaginous obstructions in the nasal passages. It consists of a thin-bladed knife, about two and one-half inches long, narrowing toward a blunted point; the cutting edge is patterned somewhat similarly to that of the modern household knife, but the knife differs from the latter in being sharpened on both sides, and this I consider a great advantage, as it thus keeps its edge better and it can be used for either side of the nose. It may safely be said that the majority of surgeons who operate on the nose have been confronted with the same obstacles which lead me to present this instrument to the profession. Among the more important of these I would mention:

1. The difficulty of catching hold of soft cartilage with a saw, owing to its elasticity and free mobility. This difficulty is overcome by my instrument, which combines the action of both saw and knife.

2. The astonishingly small amount removed at the first attempt; especially is this the case in operating on deviated septa; we begin to saw at the base, and

when we have fairly gotten hold with the saw we find our instrument at the tip of the projection. Consequently but a small portion of cartilage over the point is removed, and for the removal of the remaining cartilage a second or third operation is necessary.

3. The slowness of the operation, which generally taxes the patience of both the physician and the patient. This is a consideration of great moment in

the case of children, in whom rapidity of operation is of first importance.

A single trial of this new septum knife will convince the operator of its usefulness and advantages over the saw in removing ecchondromata and deviated septa.

My ideas were carefully carried out by W. F. Ford & Co., of New York, by whom the instrument is manufactured.

165 East Eighty-Second Street.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 9, 1897:

	Cases.	Deaths.
Tuberculosis	211	112
Typhoid fever	42	7
Scarlet fever	11	3
Cerebro-spinal meningitis	0	3
Measles	14	2
Diphtheria	154	24
Laryngeal diphtheria (croup)	8	4
Chicken-pox	1	0

Ptomain Poisoning.—Some deaths which have recently occurred in Lichfield, England, from ptomain poisoning after the eating of frozen mutton, have caused quite a flutter in the breasts of importers and purveyors of frozen meat. The *Australian Trading World*, commenting on the matter, suggests a somewhat novel theory as to the cause of ptomain poisoning—a theory which is not without a suspicion of having been suggested by self-interest. The editor holds that in ancient cities, like Lichfield, where many of the houses are from one hundred and fifty to two hundred years old, although these places may be outwardly clean, nevertheless the condition under the surface is deplorable, and that in most instances to this hidden unsanitary state must be attributed the food poisoning rather than to the meat itself.

The Temperature of Newborn Children.—As the result of a clinical study, Mühlmann (*Archiv für Kinderheilkunde*, B. xxiii., H. iv., v., p. 291) has found that the average temperature of all children does not differ from that of adults. Occasionally temperatures as low as 34.5° C. (94.1° F.) are found, but like conditions may be observed exceptionally in very old persons. The average temperature of twenty-one newborn children, however, taken in the rectum with an exposure of ten minutes, was found to be 36.3° C. (97.3° F.). No appreciable difference was noted between the temperature of boys and that of girls; the differences between the two sexes was not greater than that between newborn children of the same sex. With regard to temperature variations, there was in the twenty-one cases studied no correspondence in the daily course. A correspondence existed among a certain group of children when the temperature was taken upon the same day and in the same room. The regularity of the temperature course observed in some children did not correspond with that found in adults, maxima appearing at times during the night, and minima during the day. The maxima could not be attributed to digestive or muscular activity, as food was so given and the observations were so timed as to avoid these influences. Special muscular activity appeared without influence upon the temperature, although bathing was attended by the greatest activity and was the cause of the greatest variation in temperature. The usual influences believed to be responsible for the daily maxima in adults—*e.g.*, daylight, activity, nervous excitement, etc.—appeared without influence upon children, the temperature actually declining at a time when all of these were in operation. The belief is expressed that the most important factor in causing the variations in the temperature of the newborn is to be found in the surrounding atmosphere.

A Feat of Memory.—The purely intellectual attribute we call memory, which "is not a function, but only a resultant due to the concurrence of the various elementary functions of the mind," is capable of almost illimitable development, as Max Müller's accounts of the recitations of the Brahmins or Sir William Hamilton's references to the feats of the humanists of the Renaissance sufficiently demonstrate. Both the philologist and the metaphysician, however, are at one in thinking that the habits of the present time—above all the desultory, particularly the ephemeral, reading now well-nigh universal—are not favorable to such feats. Indeed, Max Müller says that the daily perusal of the *Times* for ten years would have sufficed to impair the strongest memory ever Brahmin possessed. That the feats, however, of a Scaliger or a Lipsius are, even at the close of the nineteenth century, quite possible, was demonstrated the other day at Sondrio (capital of the Valtellina), where the advocate Signor Edoë, professor in the Istituto di San Lorenzo, repeated, for a wager, in twenty hours consecutively—from 6 P.M. till 2 P.M. of the next day—without prompting or aid of any sort, the entire "Divina Commedia" of Dante. The achievement came off in presence of a committee of brother professors and literary men, who afterward entertained the performer at a banquet, not unwelcome, one would imagine, to either party after such an effort of brain tension and vocal articulation on the one hand, and sustained surveillance *ad apertura libri* on the other. The "Divina Commedia," I need hardly remind the reader, consists of nearly a hundred cantos, and of all poetical compositions is the least diffuse—characterized, that is to say, by the closest condensation of thought and expression. The late Duke of Sermoneta (Sir Walter Scott's *fidus Achates* on his memorable visit to Rome in 1832) could also repeat the "Divina Commedia" from first to last, but that was the result of lifelong study, not, as in Signor Edoë's case, the outcome of comparatively short preparation, begun and ended for the purpose of winning a wager.—*Rome Correspondent of The Lancet.*

Sunlight and Bacteria.—In view of the destructive effect of sunlight, especially of the blue to the ultra-violet rays, upon bacteria in water, Prof. H. Marshall Ward would explain the comparative freedom of river waters under the blazing hot summer sun from bacteria, as against the more abundant infection of the same waters in winter. Pasteur and Miguel found that the germs floating in the air are, for the most part, dead—killed, the author holds, by the sun. Yeasts which normally vegetate on the exterior of ripening

grapes are destroyed, according to Martinaud, if the heat be very intense; and Guinti has observed that the ingress of sunlight hinders acetic fermentation. When the typhoid bacillus falls into turbid dirty water in summer, it finds a congenial propagating place. The dirt furnishes it food, absorbs heat to increase the warmth, and keeps off the hostile blue and violet rays. —*Popular Science Monthly*.

A Surgeon's Culinary Skill.—According to the London *Evening News*, Mr. Lawson Tait is a wonderful cook and concocter of new dishes. He frequently invites his confrères to strange meals all the items of which have been either prepared or invented by himself.

Somatic Therapeutics.—Gain in body weight and improvement in neurasthenic conditions usually go together, but there are enough exceptions to the rule to show that nervous nutrition is something more than a mere sample of the general. The more nearly symptoms approach in character to the "fixed idea" of the insane, the less amenable are they to the beneficial effect of mere somatic therapeutics.—*Medical Times and Hospital Gazette*.

Worry.—Modern science has brought to light nothing more curiously interesting than the fact that worry will kill, and the way in which it kills is stated to be that worry injures beyond repair certain cells of the brain. The brain being the nutritive centre of the body, the other organs become gradually injured, and when some disease of these organs or a combination of them arises death finally ensues. Occasional worrying of the system the brain can cope with, but the iteration and reiteration of one idea of a disquieting sort the cells of the brain are not proof against. —*Pharmaceutical Products*.

Vital Statistics of Philadelphia.—For the week ending September 4th there were reported to the Philadelphia board of health 399 deaths, 12 more than during the preceding week, and 37 more than during the corresponding week of the previous year. Of the whole number, 159 occurred in children under five years of age. The principal individual causes of death were as follows: Pulmonary tuberculosis, 37; cholera infantum, 36, marasmus, 26; heart disease, 25; nephritis, 21; gastro-enteritis and old age, each 18; diphtheria and pneumonia, each 17; apoplexy, carcinoma, and convulsions, each 13; typhoid fever and inanition, each 11; inflammation of the brain and whooping cough, each 10. There were reported during the week also 80 cases of typhoid fever, 67 of diphtheria, and 35 of scarlet fever.

Bacterial Mud.—An instance of oxide of iron associated with bacteria occurring on a large scale has been investigated by Prof. Manabu Miyoshi, who holds the chair of botany in the University of Tokio in Japan. The material examined by him was a ferruginous mud from the hot springs of Ikao. This mud consists entirely of bacteria. The bacteria seem to resemble the leptothrix ochracea of Kütz, but further observations will be necessary in order to determine whether they constitute a new species or not. From experiments made with hydrochloric acid Professor Miyoshi is led to believe that the oxide of iron is not deposited on the walls of the cells but is more or less intimately incorporated with them. No others of the more common iron-containing bacteria, such as crenothrix Kühmana, were found in this particular mud.—*Lancet*.

Health Reports.—The following statistics concerning yellow fever, cholera, plague, and small-pox have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended October 9, 1897:

		Cases	Deaths
Yellow Fever—United States.			
Alabama, Aleo	October 5th	1	
Mobile	October 1st to 8th	4	
Louisiana, New Orleans	October 1st to 6th	277	20
Mississippi, Inverness	October 1st to 6th	111	5
Clinton	To date (October 8th)	10	1
Edwards	October 1st to 5th	116	11
Henderson's Point	October 7th	3	
McHenry	October 1st to 5th	2	
Natta Yuma	October 1st to 6th	2	
Scranton	October 1st to 7th	6	2
Yellow Fever—Foreign.			
Brazil, Para	September 11th to 18th	..	3
Cuba, Cardenas	September 11th to 25th	..	5
Matanzas	September 22d to 29th	..	3
Santiago	September 18th to 25th	..	10
Jamaica, Kingston	August 28th to September 12th	5	4
Mexico, Mazatlan	September 25th to October 2d	..	9
U. S. of Colombia, Panama	September 13th to 23d	1	1
Cholera—Foreign.			
India, Bombay	September 1st to 7th	.	37
Calcutta	August 21st to 28th	.	5
Madras	August 28th to September 3d	.	21
Japan, Osaka and Hiogo	August 28th to September 4th	.	1
Plague—Foreign.			
India, Bombay	September 1st to 7th	..	23
Small-Pox—United States.			
Alabama, Bessemer	September 25th to October 2d	1	
Small-Pox—Foreign.			
Bohemia, Prague	September 11th to 18th	2	
Canada, Montreal	October 1st to 6th	1	
Egypt, Alexandria	August 15th to 21st	.	1
Cairo	August 13th to 26th	..	2
England, Sheffield	September 11th to 18th	1	
India, Calcutta	August 21st to 28th	.	1
Madras	August 28th to September 3d	..	2
Scotland, Glasgow	September 11th to 18th	..	2
Spain, Barcelona	[illegible]	..	2
Madrid	September 7th to 14th	..	2
Russia, Moscow	September 7th to 13th	1	
Warsaw	September 11th to 18th	..	5

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

LECTURES ON THE ACTION OF MEDICINES. By Dr. T. Lauder Brunton. 8vo, 673 pages. The Macmillan Company, New York.

ESSENTIALS OF OBSTETRICS. By Dr. C. Jewett, assisted by Dr. H. F. Jewett. 12mo, 358 pages. Illustrated. Lea Brothers & Co., Philadelphia. Price, $2.25.

TUBERCULOSIS OF THE GENITO-URINARY ORGANS. By Dr. N. Senn. 8vo, 317 pages. Illustrated. W. B. Saunders, Philadelphia.

CIRCULATION OF THE CENTRAL NERVOUS SYSTEM. By Dr. Wm. Browning. 8vo, 173 pages. Illustrated. J. B. Lippincott Company, Philadelphia. Price, $1.50.

A CLINICAL REVIEW ILLUSTRATING THE DIFFERENCE BETWEEN ASEPSIS AND ANTISEPSIS.[1]

By J. BLOCK, M.D.,

[illegible]

THAT medicine as an art had its origin in a spirit of benevolence seems easily conceivable, observing the promptness and eagerness with which the modern practitioner, whether surgeon or physician, exhibits or applies a drug or chemical. The ways of the primitive man are reflected by the hurried application of this or that remedy or dressing, lest something be left undone, though occasionally we find a physician betraying less of this solicitude for the art than an aptitude for observing nature's masterly methods. Though here and there we find a Louis, or some master mind absorbed in the study of nature's revelations, deducing laws for practical guidance that distinctly indicate a *noli me tangere*, the atavistic tendency has such a firm grasp upon the mass of the profession that the appearance of any nostrum, whether it be a mud or a vapor (of course under some less antiquated name), is hailed with delight and accepted without recognizing its limitations for good or its positive influence for evil.

This benevolent desire to do something for the sufferer, descending as a heritage from one generation of medical men to another, has finally developed into an instinct difficult to eradicate. It is clear that in the very beginning of a society indicating even a rudimentary division of labor the man set aside to care for the sick and the wounded, governed by an impulse to preserve his kind, regarded nature as his enemy, and, loth to accept her teachings, poured the supposed balm upon their wounds, to be finally delighted with its fancied effect when she rose superior to a twofold infliction. Even to-day the inexorable law of heredity is revealed in the imitative faculty, the frock of the modern practitioner scarcely sufficing to conceal the simian appendage of his remote ancestor.

It remained for two Frenchmen to determine the something in the air, previously mysterious and mystifying, which in the one case sustained organic life and in the other destroyed it by parasitic devastation. The great chemist, Lavoisier, laid the foundation for modern chemistry by the discovery of oxygen as a ponderable something upon which terrestrial existence depended; and his worthy successor, Pasteur, in another department, contributed the substratum for modern bacteriology by revealing the presence of something else in the air, upon which fermentative processes depended, little dreamt of by his illustrious predecessor.

Lister, to whom humanity must ever remain grateful, a pioneer in a hitherto practically unexplored field, still fettered by the inexorable statute of heredity, proceeded to destroy the pestiferous micro-organism, assuming a belligerent attitude with devices for offensive warfare best suited to the purpose and the maxim "eternal vigilance is the price of life and health." That he suspected his agents to be as formidable to one organism as to another must be evident to those who practised his methods when first introduced; his protective immediately applied to the tissues being in evidence. He was the father of antisepticism. What he scientifically demonstrated was empirically practised by his predecessors. Though essaying to be prophylactic, it was essentially therapeutic. He was still the chemist, and not the broad-gauged philosopher peering into the grand vista of future preventive medicine.

Perhaps the title I have chosen under which I might present a summary of a few cases recently under observation is not altogether literally fitting; but it is often found more convenient and perhaps more effective to demonstrate a thing by what it is not than by what it is, and with a view of eliciting a discussion from the fellows on a subject perhaps trite to some, but to me always new and attractive, I attempt to include the following report under the above caption:

CASE I.—Miss F——, about nineteen years of age, first consulted me for what was clearly a case of chronic appendicitis of four months' standing; sharply acute at first, becoming chronic with a continued fever, pain, intestinal disturbance, right iliac, lumbar, and hypochondriac intumescence and tenderness, extreme flexion and adduction of the corresponding thigh and leg, with a degree of fixation suggesting disease at the hip-joint. Operation was declined, and after a month's observation and simulated treatment she so far improved as to be able to return to her home, fancying she had escaped the knife of the surgeon. This was four years ago. During the succeeding years she had recurrent attacks, never so accentuated or serious, however, as the primary invasion. Finally, becoming disgusted with a state of chronic invalidism, she returned for operation. This was performed with the usual pre-operative and postoperative precautionary measures. Before the incision was closed the extensive intestinal adhesions were broken up and a drainage was placed over the site of the appendical stump. The wound was dressed with the customary iodoform gauze, and renewed *secundum artem* after the fourth day, when the drainage was removed. I wish to call your attention for further reference to the last item in this short narration of a very interesting case. The patient made an uneventful recovery with very slight reaction, and was dismissed from the hospital at the end of three weeks, much improved and without subsequent trouble, save the appearance later of a small hernia at the site of the drainage, for which I finally succeeded in persuading the young woman to submit to another operation for its closure, upon my return from my summer vacation. This was done in the following manner: An incision including the entire length of the old cicatrix exposed the muscular and fascial planes of the former wound; the latter (the abdomen at this point being rather thin) were divided with a knife so as to represent two superimposed halves, each of which was stitched by a running suture of chromicized gut, after the manner of Edebohls. The skin was closed by a continuous suture of plain gut sterilized with sublimate, and the wound sealed

[1] Read before the Kansas City Academy of Medicine, November 29, 1896.

with seven or eight narrow strips of iodoform gauze and a ten-per-cent. solution of iodoform collodion. There was practically no reaction and recovery was apparently uneventful. On the tenth day, however, the attendants became alarmed, or perhaps suspicious that all was not well; an oozing about the margins of the gauze placed over the seal, and an annoying burning and pruritus over the abdomen of the patient, calling for a removal of the dressings. This revealed a primary union of the wound and absorption of the external suture, but the skin of the abdomen presented an intense mahogany-colored injection, interspersed with coalescing and confluent vesicles, large bullæ distended with pure serous fluid, which had given way at some places, so that the upper layers of the derma were displaced in large strips with an exposed oozing surface underneath—in short, an iodoform dermatitis. A dusting-powder of talcum fortunately put an end to the antiseptic disease, but what a fertile soil for a serum culture and subsequent infection had not the wound closed primarily. This wound, made with aseptic preliminaries (the catgut prepared by myself and subjected to culture experiments proving its sterility), was unnecessarily supplemented and endangered by antiseptic provision, and convalescence was prolonged.

Case II.—A robust individual in the neighborhood of fifty, so devoid of intelligence as to be on the brink of idiocy, therefore incapable of furnishing any reliable antecedent data, first consulted me about two years ago with what objectively proved to be an obstinate sciatica, which yielded to cauterization repeated at intervals of five days, the iron being applied some five or six times. About four months ago he again applied for treatment, claiming to have the same affection in the opposite member, and insisted upon an application of his old friend, the cautery. Not being able to elicit any history and observing an incipient lameness, I accommodated him. Some four or five days thereafter, being summoned to his home, I found him suffering excruciatingly, and, pushing my investigation, diagnosticated an osteo-periostitis of the upper third of the fibula, advising incision, to which he objected. After a week's flirtation with morphine and poultices, he finally consented to go to the hospital—a free incision evacuating the pus confirming the diagnosis and bringing prompt relief. Iodoform packing after the usual manner, subsequent flushing with sterilized water, and redressing at intervals. During my absence a colleague kindly consented to care for the case, and upon my return informed me that the iodoform proved so irritating that he was obliged to substitute boric acid. About seven weeks ago I proceeded to the removal of an almost cylindrical sequestrum, incising the cicatrix, thoroughly removing all adventitious material with the knife, scissors, and curette—converting the entire field into a clean aseptic ground, but, unmindful of my colleague's previous experience, resorted to the stereotyped iodoform tamponade. There was absolutely no reaction; pulse and temperature were normal. On the fourth day the dressings appearing saturated, I removed them, expecting to encounter a serous oozing from the wound, but instead exposed the packing in the eight-inch incision dry and sweet, but found the epiderm of almost the entire leg practically lifted *en masse* by a series of enormous bullæ, a few remaining unruptured—an iodoform dermatitis. Nor was the effect limited to a local disturbance. Though plain gauze dressings and asepticized-water lavage with sterilized talcum dustings over the denuded derma secured an aseptic course in the healing of the wound, an intensely pruritic generalized reflex eczema set in, with gastro-intestinal disturbances difficult to control. The eczema still remains in patches, with a prospective chronicity not very complimentary to the surgeon. As in the former case, the thoroughness of the asepticism proved a safeguard against the possibility of the stupid antisepticism employed in the face of previous warnings.

In considering the disastrous effects of the antiseptic, several cogent objections may be urged against my aversion to the employment of this particular agent. It is possible that it was impure and that the impurities were responsible for the dermic lesion. Yet the operations were performed in two different institutions, though it is very probable that the chemical was derived from the same source. Again, individual susceptibility or idiosyncrasy may be invoked as a possible explanation. But are we always able to determine this in advance? Finally, the degree of concentration of the drug and the unnecessarily prolonged contact of the dressings may have been responsible. In the first case this was probably true, for no untoward effects were observed when the dressings were changed after the fourth day. In the latter the period of immunity from irritation, if this was an element in its production, must have been much shorter. But though all this may be true under modern methods and practice, the longer the primary dressing may be allowed to remain the better, wound rest being no inconsiderable factor in the promotion of primary union. I do not underrate the value of this excellent drug where it is clearly indicated, and am not very partial to the many substitutes that are being continually offered to the profession, realizing the pithiness of the remark of Mosetig, that "though there were many chancellors, there was but one Bismarck," when extolling its virtues; yet I cannot help believing that it adds nothing to the assurance of a thoroughly asepticized wound, but often offers a premium for a local or systemic conflagration. To see the surgeon applying his dressing, the perforated container in hand, dusting the wound with an air of satisfaction as he views his work, one would think he would no more omit this pleasing stroke than the seasoning of his steak, the penetrating odor of the one being as important as the savor of the other. Surely this must be from force of habit, since there can be but little good reason for this final ceremony.

Case III.—Mr. W——, aged fifty, of good habits, whose previous history is unimportant, save a very remote syphilis, met with a painful accident some two months ago while riding, both horse and rider falling. The animal fell in such a manner as to crush the patient's right leg to the ground, the brunt of the force coming upon the antero-lateral face of the member, just above the knee-joint. Though the whole leg below this point exhibited evidences of a contusion in an iris-hued swelling, just above the patella there was a superficially contused lacerated wound—indeed, little more than an abrasion, exposing in part the corium and at other points the subcutaneous fat, as though excoriated by particles of sand. The surface might have extended over an area, say, of about one and one-half inches square; beyond, looking toward and including the surface to the biceps tendon, and extending upward above the wound for about one inch, the parts looked angry and inflamed. There was no constitutional disturbance. It was doubtful whether he was more than momentarily stunned at the time of the accident. He complained of some headache on the same side and pain about the shoulder, though an examination presented no gross evidences of injury at these points. I first saw him about two days after the accident, some domestic remedies and dressings having been applied meanwhile. From the first I felt confident that the parts included in the brush burn would slough, and so informed the patient, and after cleansing the parts prescribed lead-and-opium lotion and absolute rest in bed. My prediction proved true, and nature was soon

throwing up a line of healthy granulations about and underneath the superficial slough, though the exposed area as well as the skin about the knee-joint was at times painful and even tender, especially after motion. The headache and pain about the shoulder disappeared. The patient grew restive and impatient, regarding the injury as trivial, objected to his enforced confinement, and in about ten days insisted upon applying a dressing relatively permanent, so that he might at least sit up. Submitting under protest, I again cleansed the wound and adjacent area, removing the hair by shaving, omitting the customary iodoform dust, not from choice, but in deference to the sensitive olfactories of his wife, who had some vague notion regarding its reputed unfortunate associations; and applied another less odoriferous substance upon plain gauze, inclosing the whole with absorbent cotton and a light bandage, telling the patient he might sit up with the leg supported upon a chair, and left him with the injunction not to go about and to inform me at once if it proved uncomfortable, for I told him plainly that I had misgivings as to the result. When I was summoned the following morning, he complained of an aching and fever in the parts, and removing the dressing I found not only the wound dry, angry, red, and swollen, but the parts beyond, especially over the edge of the vastus externus and in the sulcus between it and the external hamstring. The former lotion was reapplied and absolute recumbency enjoined, and calling again in the afternoon I found he had had a chill with the usual constitutional disturbance accompanying a local inflammatory reaction; a spreading erysipelas soon set in, extending up the thigh and down the leg, and an area the size of a silver dollar, opposite and distinct from the abrasion above and external to the patella, began to slough, opening a communicating branch from the external to the internal saphenous and exposing the outer hamstring tendon. The usual constitutional symptoms of varying severity accompanied the erysipelas for about ten days, and during the sequestration of the slough an annoying hemorrhage, though not difficult to control, added to the anxiety of the sufferer and his friends. After the parts had cleaned off and begun to granulate, the exposed surface proving refractory because of its relations to the tendon, it required more than a month's splintage and dressing before it would heal.

Case IV.—Mr. B——, aged forty, of large frame and somewhat inclined to obesity, of temperate habits, but old specificity, consulted me upon a Saturday some six weeks ago, for what appeared to be an ischio-rectal abscess just beyond incipiency. He had a cough of which he made light, and some little fever. I advised incision to prevent fistula, but he preferred a poultice and asked for delay. When he called again Monday, with the local condition much aggravated, I insisted upon his repairing to the hospital at once for operation. On the following morning, under anæsthesia I incised the swelling. At that time the whole left ischio-rectal base was swollen, œdematous, bright red, and fluctuating. Making a large longitudinal incision midway between the anus and tuberosity, I was surprised, after the thin, horribly fetid ichorous fluid was evacuated, to find the entire space greenish and black with a gangrenous mass, to remove which I made a transverse incision to the tuberosity and another around behind the anus to the right, as it had already extended in that direction. Everything was thoroughly cleansed, exposing the rectum and levator ani, leaving a cavity admitting a good-sized fist. After packing the cavity with iodoform gauze and applying the bandage, I noticed a small arborescent engorgement superficially located about the raphe of the scrotum, inclined to lividity. By evening I found the constitutional symptoms more pronounced, the patient inclined to wander, and perspiring profusely. When he was placed upon the table the next morning, after removal of the dressings marked evidence of an extension of the process was present. The scrotum was enormously swollen, œdematous, and livid, and the scroto-femoral space up to the groin swollen and red; and continuing the incision up into this region I found the subcutaneous tissue black and the odor frightful. Removing the sphacelated mass, the same dressings were applied. Whiskey in abundance and strychnine were prescribed. The patient grew steadily worse and the sweats profuse; in a word, he was profoundly septic. On removing the dressings the next day the wound looked red and dry, with a scarcely perceptible secretion at a few points, and the scrotum was larger, but there was no fluctuation to indicate the presence of pus. Lateral incision into the purse revealed neither sphacelus nor fluid. The urine was examined, but found negative as to albumin or sugar. I renewed the dressings, dusting iodoform lightly over the entire surface. Subsequently, fearing the possible constitutional effects of the chemical, I substituted Peruvian balsam, but without inducing the presence of a healthy secretion. A colleague, seeing the patient with me, suggested packing with an antiseptic preparation, which in sheer desperation was adopted. Up to that time, although there was but little secretion, the surface was comparatively clean, no longer malodorous, and the surrounding tissues about the buttock and in the groin were only slightly hyperæmic, showing the ordinary circumferential erythema of limited area about open wounds; the scrotum was, however, still largely swollen and blue. A small incision into the raphe proved the tissues underneath free from gangrene. The next day the wound surface assumed a grayish or rather opalescent appearance, the margins became slightly indurated and darker, and upon the following morning, the dressing having been renewed, the appearances were more pronounced—diphtheritic-like upon the surface, with brawny livid borders and an extending erythema suggesting erysipelas. Constitutional symptoms worse: delirium, chills, rapid and weak pulse, and dark tongue, and high temperature. The erysipelas spread rapidly upon the left thigh to the knee, around the back and buttock on both sides, and half-way up the right thigh, with a number of phlegmons. Though the case looked hopeless, we dropped all antiseptics, using sterilized gauze dressings and sterilized water, pushing the whiskey and strychnine, with codeine for the violent cough caused by a dry bronchitis, and morphine at night to quiet the delirium. This process continued for about fifteen days, with repeated chills, colliquative sweats, and pulse at times reaching 160, though in the mean time the wound surface began to secrete clean pus and the scrotum toward the end of the erysipelatous process began to undergo resolution. After much labor and painstaking dressing the patient now, after nearly six weeks, has so far progressed as to be free from fever, with a clean tongue and good appetite, and the wounds are reduced to about one-fourth their original dimensions, though he still has a frequent pulse and a furunculosis of the scalp, but is now very certain of an escape from what seemed almost certain death.

Reviewing the last two cases, I shall anticipate two or three very probable criticisms from those I have the honor to address, viz.: that the appearance of that dreaded malady, erysipelas, and a change in the dressings were merely coincidences; or perhaps that the infection was conveyed from the one to the other; and, last but not least, that the presence of the streptococci about sloughing wounds is very prone to cause diffuse inflammatory processes.

But I take it that all three of these explanations are not very tenable but are susceptible of successful con-

troversion. In both cases the appearance of the spreading infection followed too closely upon the change of treatment to be ignored as a factor; had it occurred in only one I might rest content and not accuse the much-lauded antiseptic preparation, but I cannot refrain from the aspersion in the case of two such apparently positive indictments. Had the man with the contusion been infected subsequent to the gangrenous case, I might have thought myself the culpable carrier of the infection; but the reverse was true. Besides, during this period I performed quite a number of important operations and assisted several friends in many more, some of which were capital, and in no single instance was there a repetition of this experience. Finally, it is doubtful that the gangrenous case had a streptococcus etiology. Though there was no macroscopic connection with the bowel, might there not have been a virulent coli-communis infection? or, as suggested by my colleague, the bacillus fœtidus may have been the infecting agent. Here it might be pertinent to remark that though the subcutaneous tissues were gangrenous, the skin was not involved and there was no emphysematous crackling to suggest malignant œdema, nor was the sufferer a broken-down subject, but apparently in the vigor of health with only this as a possible mode of infection. He supposed himself chafed, and applied some old patent ointment recommended and furnished by a friend. It was said to have been exposed several months and possibly had become rancid. Surely the vascular supply in the fossa is so free that sloughing from obstruction could hardly be thought of.

By returning to the study of nature's methods of repair in wounds, we may possibly get a hint as to what is meant by meddlesome antisepsis. Is it not plain that an antiseptic agent to be availing must be of sufficient strength to destroy the micro-organism to whose presence is chargeable the septic process with which the practitioner is contending? Is it not equally true that to be effective it must be renewed or continuously present in that degree of concentration scientifically determined as inhibitive to the growth and development of succeeding generations? Is it to be supposed that the territory upon which this warfare is being waged remains indifferent to the ravages of the contending forces?

Tissues already impaired by injury or disease require but the devitalizing contact of some chemical to render them a suitable pabulum for the omnipresent micro-organism. The delicate barriers that nature has put up as a defence against further damage, becoming gradually maturer and stronger in response to the demand for tissue repair, are ruthlessly swept away in their incipiency, by assuming that the host has greater endurance and vitality than the parasite. Is not this notion contrary to the teachings of bacteriology? Is it not contrary to common sense? Is there any ground for believing that, in obedience to antiseptic idealism, the tissues electively resent the presence of the germ and welcome the chemical?

Those engaged in sterilizing ligatures and dressings by chemicals or heat tell us of the high concentrations and prolonged contact of the one or continued exposure to the other necessary to be effective. If this is true, why should we depend upon lesser potencies to accomplish the purpose in diseased or injured tissues? If of full strength, why should they not be as destructive to the latter as to the intruder? A little unbiassed reflection, and it must be evident that asepsis and antisepsis are different etymologically as well as surgically. It is not true, as has been advocated by antiseptic enthusiasts, that it is merely juggling with terminology. While asepsis is antiseptic, antisepsis is not aseptic. Of what use are antiseptics in tissues pullulating with infective material? Is it not a reminder of the legendary attitude of the ostrich, or the method of the indolent housewife concealing the filth upon the shelves and furniture by tawdry contrivances of paper or other cheap material? Of what avail if the field of operation or injured territory is properly aspeticized? Is not the bacteriologist content with a cotton plug to resist intrusion when preparing his culture tubes? If this method answers the exacting demands of the most delicate of all scientific studies, why should we not be content with an aseptic protective envelope?

Again, if the current trend of research is correct, why are investigators abandoning chemicals and seeking to recover nature's essences of immunization for practical application? To treat an individual already septic either locally or constitutionally with antiseptic drugs or chemicals in the doses tolerated is homœopathy as to effect, and may be aptly compared with veterinary practice if the dosage exceeds this. In the one instance the result would be *nil*, in the other it would increase human mortality without appreciably affecting that of the microbes—another instance of the vagaries of modern medicine.

For years, despite the exhibition of every new antiseptic introduced to the profession, we have been obliged to rely upon stimulants to sustain the powers of life and intestinal and local drainage, pending the self-immunization of the septic patient, and as yet there remains no case or series of cases with incontrovertible proof that recovery ensued consequent upon the administration of drugs alone. In a word, it has been a natural result achieved after the manner of bacteriological laboratory experiments in immunization. As yet, therefore, our great hope for the future looks to prophylaxis and not to cure; to asepsis and not antisepsis.

Reserve your antiseptics in injuries and wounds intentionally induced for the sterilization of surgical material, instruments, and the healthy tissues of the operator, and render the field of operation aseptic mechanically, if at all possible, and you will then aid and not handicap nature in her processes of repair. The dressings should be sterilized by heat when practicable, and if not the chemicals, after having rendered the ligature or suture material aseptic, should themselves be eliminated to prevent irritation. An ideal dressing fulfils the physiological and bacteriological indications mechanically when it is light, porous, absorbent, and aseptic, providing for drainage and support, and sufficiently occlusive to maintain the surgical cleanliness originally provided, thus insuring physiological rest, avoiding the necessity for frequent changes—a most important factor in the successful management of wounds.

If Hilton had done nothing else, he merits everlasting praise for the classical manner in which this was demonstrated in his "Rest and Pain." Surgery is not a question to be solved by chemicals, but essentially one of mechanics. In injuries and wounds not susceptible of permanent dressing, primary cleanliness, mechanically induced with a knife, scissors, curette, and brush, will in the majority of instances fare better with simple aseptic gauzes, wools, etc., and boiled pure water for the removal of detritus and discharges. This recommends itself at once as inexpensive, efficient, and not likely to interfere with nature's kindly help. Medicine and surgery are human institutions and therefore imperfect, and can approximate perfection only by utilizing the devices of nature and not running counter to them. Observe and then imitate her. Reserve your chemicals for specific ulcers, sinuses, suppurating cavities, where from necessity or from choice mechanical interference is either declined or impossible. Here they may be useful to disinfect or correct foul discharges, stimulate repair, anæsthetize

locally, or minimize septic absorption; but be sure that in trying to cure one evil you do not substitute another perhaps worse.

The ancients imagined they saw their enemies in the original four elements; let us destroy those in the air and in the earth by fire, and employ fired water as a convenient vehicle to dispense the blessings of a more enlightened pathology.

SOME PRACTICAL DEDUCTIONS FROM BACTERIOLOGICAL RESEARCH.

By GIVEN CAMPBELL, M.D.,

ST. LOUIS, MO.

In presenting this paper I have thought it best to consider it under two heads: first, to review some of the important facts of immunity and predisposition, and second, to see how we can apply these facts in the treatment of our patients. As is of course known, immunity is the name given to that condition of an animal's body which enables it to resist the attack of an infectious disease, being in contrast with predisposition or that bodily condition which must exist in order for the germ to grow at the expense of the body and thus produce that train of symptoms we call an infectious disease. The importance of these laws of immunity cannot be overestimated. Bacteriology is important to a physician in two ways: First, as an aid to diagnosis, and second, in enabling us to understand the laws of immunity. The first is fairly well understood by all of us and we find its knowledge useful, but the second is of vastly more importance and unfortunately is not so generally studied as its importance merits; and in my opinion a broad knowledge of the laws of immunity will go farther toward making a successful physician of one than any other one study. We will now first consider the circumstances under which the system is found immune, and then the direct mechanism of this immunity so far as known. We find immunity and predisposition running through the entire animal kingdom. The invertebrates are subject to certain diseases to which the vertebrates are immune, and *vice versa*. One germ is able to attack fowls and rarely mammals, another can attack mammals and not fowls. Herbivorous animals are predisposed to disease to which carnivora are immune.

Field mice and house mice each have diseases peculiar to themselves. Different races of men have immunities from different diseases, and individuals of the same race, yes, even of the same family circle, exhibit marked differences in their power to resist an infectious disease. Many of these differences seem easy of comprehension. To explain others, our knowledge is not sufficiently complete. The different immunities in the gross divisions of the animal kingdom probably depend on the great differences in the anatomy and physiology of these animals. Thus, frogs are immune to anthrax, the bacillus of which does not grow readily at a temperature so low as that of their bodies, but if a frog is immersed in warm water and its body temperature raised to a point near that of warm-blooded animals, it becomes susceptible to the disease; and again, if a hen, whose body temperature is higher than that at which anthrax best grows, be refrigerated before inoculation with anthrax, it takes the infection, while if not so chilled it is immune. This refrigeration may not be the only cause of the immunity, but is probably *a* cause, and many more such instances could be cited.

The most probable explanation of race immunity is that an immunity is built up in certain races of men by a process of hereditary selection. A certain race is exposed to the ravages of a certain disease. Certain individuals of that race are more susceptible to that disease; others are less so. Those most susceptible die and are not liable to leave offspring. Those more immune live and produce children who probably inherit the immunity of their parents, and those to whom the immunity does not descend die and the others live, and thus the disease constantly weeds out the susceptible and leaves the immune until a race immunity is built up. Thus we know measles is a mild disease with us, but some years ago the disease was conveyed to the Pacific Islands by a European child. The disease had never been known to exist there, and thus implanted on a virgin soil it became very virulent and was fatal in a large percentage of cases. The rise and fall of leprosy in Europe after the crusades is possibly dependent on the above cause. Of course, when a member of one race is transplanted to another race and climate, he loses the protection of his hereditary immunity, for he is exposed to a new set of diseases and his vital expectancy is lowered (witness the much higher mortality of our colored than of our white population). Before considering the direct mechanism of immunity let us consider some of our means of increasing or diminishing immunity. Immunity is produced or increased by having the disease in question. This usually confers an immunity lasting a variable time, but longer in a general infectious disease than in a local one, yet the remarkable fact exists that a local infection will often produce a persistent local immunity. Thus the ear of a rabbit may be inoculated with erysipelas and an infection produced which is limited to that ear, and while the other ear may be subsequently infected, the one in which the infection has taken place remains immune for a period of many months. Other means of producing an acquired immunity are: 1st. To inject gradually increasing doses of the toxin of the disease. 2d. Infection with a similar but milder disease, as vaccinia or rabies. 3d. To inject the toxin of some other germ. 4th. To inject the serum of an animal immune to the disease in question. Immunity may be lessened by, 1st, local injury to the body; 2d, by fatigue of individual; 3d, by change of body temperature; 4th, by modifying the reaction of blood or tissue; 5th, by increasing the virulence or numbers of infecting organisms; 6th, by injecting together with the organisms, first, certain chemical substances; second, the toxin of the germ itself; third, some other germ or its ptomain (and please notice that this other germ need not be a virulent one, nor its ptomain poisonous).

Passing on to the direct mechanism of immunity let me state that, while some other elements may enter slightly into its production, immunity depends chiefly on two factors: 1st, the presence in the body, naturally or acquired, of some chemical substance which increases the vital resistance of the body to the toxin of the germ; and 2d, the activity of the phagocytes in destroying the germs. Our reason for believing in the first of these factors depends on the following experiments, which have been frequently repeated and thoroughly verified: Ordinary sterile bouillon may be prepared, and a number of guinea-pigs procured; into each of several of these guinea-pigs one-tenth cubic centimetres of this bouillon is injected. No harm results in any way. Now more of this same bouillon is inoculated with the tetanus bacillus, and after growth has taken place the bouillon is filtered through a Chamberlain bougie, and thus all the bacilli are removed and nothing but substances in solution in the bouillon pass through the bougie. More of the guinea-pigs are now selected, and into each of these one-tenth cubic centimetre of this filtrate is injected.

All these guinea-pigs exhibit tetanic spasms and die. The bouillon has undoubtedly changed, and this new property is not due to the presence of the bacilli, for they are absent, but must be due to something in solution in the bouillon. A horse is now procured and his immunity to tetanus is greatly increased; the horse is what is called immunized. Take the blood serum from this horse and mix one part of it with five thousand parts of the filtered bouillon which, we have just seen, kills guinea-pigs in the quantity of one-tenth cubic centimetre. Take more of the guinea-pigs and inject into them of this mixture amounts varying from one-tenth cubic centimetre to one cubic centimetre, and even much more. It will be found that they have suffered no harm. Something then was present in the serum of this immunized horse which prevented the poison produced by the tetanus bacilli from affecting the guinea-pig. If the serum of a non-immune horse be mixed with the bouillon it does not prevent the bouillon causing death to the guinea-pig, so it must be something formed in the horse's blood during immunization. No bacteria are present in the horse's blood, and there is every reason to believe the substance in question is an albuminoid substance in the nature of an enzyme. Now we have seen that the symptoms produced by the filtered culture broth are very similar to those produced in an animal by tetanus itself, and, moreover, we can take the blood serum of an animal dead of tetanus, and after proving it free from the bacilli of tetanus inject it into a guinea-pig and produce death with the same symptoms, and, further, we can mix immune serum with this serum and thus neutralize its effects. The severity of the symptoms produced by the filtered bouillon and by the serum from an animal dead of tetanus varies directly as to the quantity injected, and does not so vary when inoculation with the bacilli takes place. So we may safely conclude that the bacillus of tetanus makes a toxin in the body of an animal similar to that which we have seen it make when grown in bouillon. And again, an animal suffering from the disease itself, if injected with the blood serum of an animal immunized to tetanus, recovers, or if injected before inoculation with tetanus proves immune, while a control animal similarly affected and without the serum of an immunized animal invariably dies; so there is every reason to believe that the animal owes its immunity to the serum from the immunized animal counteracting the effects of the poison—which brings us to acknowledge that immunity to a disease is accompanied by the presence of some substance in the blood and serum which counteracts the effects of the poison made by germ of that disease.

As to just how this immunity-giving substance acts we are unable to say. It certainly is not in any way a disinfectant or antiseptic, for tetanus bacilli will grow freely in highly antitoxic antitetanus serum. It is not a chemical antidote, for a mixture of toxin and antitoxin which is perfectly harmless to one animal is fatal to another kind of animal. It is not a physiological antagonist to the toxin, for its injection without the toxin produces no symptoms, nor does it in any dose produce symptoms opposite to those of toxin. Its action probably is to increase the vital resistance of the body in general and of the leucocytes in particular to the action of the poison. Once formed it persists in the immune animal and is not readily eliminated from the body; some of it is lost, however, for animals rendered immune while pregnant give birth to young in which the immunity is also present, and the amount lost continues probably to be replaced, and thus immunity is preserved.

The second factor in the mechanism of immunity is the activity of the phagocytes in destroying bacteria. The theory of phagocytosis is well known, and the profession is too well acquainted with it for me to give any lengthy description of it here. As will be remembered, the theory was first ardently supported and then just as completely dropped. As is quite often the case, truth lay in the mean between opposing opinions, and our best knowledge seems to indicate that phagocytes do engulf and destroy bacteria, and living bacteria at that, but that their ability to do so depends on the absence of the toxin of an organism which is pathogenic for the individual. When a capillary tube, closed at one end, and containing a culture of a non-pathogenic germ, is introduced under the skin, vast numbers of phagocytes enter the tube and in a short time have engulfed and destroyed the germs. If the tube contain a culture of a pathogenic germ very virulent to that animal, no such condition occurs, but on the contrary the phagocytes retreat from near the tube. This ability of the phagocytes to seek and destroy bacteria is called chemiotaxis, and the presence of the toxin of a pathogen paralyzes it, as do also the toxins of other bacteria if present with the one inoculated. This phagocytosis is not the only part the leucocytes take in immunity. There is good reason to believe they are the chief factors in producing the antitoxin, and Kanthack has reported some observations which, if confirmed, will prove very important.

He and Hardy added anthrax bacilli to a drop of frog's lymph and examined them under the microscope for four or five hours. The first thing noticed was that the eosinophilous leucocytes moved up to the bacilli and arranged themselves along them. Then the protoplasm of these leucocytes underwent rapid streaming motion and the cells discharged their coarse granules at the bacilli. These granules dissolved in contact with the bacilli and the bacilli were readily seen to become granular and disintegrated. All this time the true phagocytes have kept out of the way. But they now come forward, arrange themselves in a plasmodial mass around the bacilli, and the eosinophilous leucocytes retire. These phagocytes now engulf the fragments of the bacilli and finally separate and complete their digestion of the bacilli apart. The reason we believe that the phagocytic theory holds good, so far as stated, are: first, the phagocytes can be seen in the act of engulfing bacteria; second, these bacteria can be seen to disintegrate and disappear in the body of the phagocyte; third, destruction is greater when the animal recovers; fourth, bacteria to which phagocytes exhibit positive chemiotaxis are destoyed, and bacteria to which phagocytes exhibit negative or no chemiotaxis are much more virulent for the individual; fifth, the fact of chemiotaxis itself is a proof.

The argument has been advanced that while phagocytes do engulf and destroy bacteria, they do so only to those already killed by the disinfectant action which blood serum to some extent possesses. Against this it may be said: first, that when the struggle between the system and the germ is evenly matched, phagocytes may be seen to engulf bacteria, and these bacteria grow inside the bodies of phagocytes, the phagocyte being thus destroyed and the living bacteria being liberated; second, that phagocytes destroy germs in an animal whose blood serum has no such antiseptic action as that mentioned above; third, that in a non-immunized animal no phagocytic destruction of bacteria takes place, while after immunization the germs are readily destroyed, but the disinfectant action of the serum may be greater in the first case than in the second; and fourth, that bacteria which would be quickly destroyed if injected into the body live and grow if placed inside the body, but protected from phagocytes by interposition of an animal membrane.

We thus have two factors in the defence of the system: first, the presence in the body of an antitoxin, a chemical

substance probably albuminoid in nature, which increases the vital resistance of the body to the toxin of the germ and thus neutralizes all the bad effect of the disease (for, practically speaking, the only means the germ has of harming the body is through the toxins it can produce); and second, that after the effects of this toxin have been neutralized (and not until then) the phagocytes destroy the bacteria and thus prevent the formation of any more toxin; and that, besides the phagocytes destroying the bacteria, other forms of leucocytes are probably largely instrumental in forming the antitoxin. We saw above that blood serum has some bactericidal action, but this action is really much greater outside the body than in it, and probably plays a very small part in immunity.

Going to the second division of this paper, the practical application of bacteriological knowledge, I desire to preface my remarks by the statement of a fact, familiar to all of us but not often enough remembered. An individual's chance of having an infectious disease may be weighed by a balance which contains on one side the amount of his natural or acquired immunity, and on the other the number and virulence of the infecting organisms. As the balance leans, so do his chances incline. Now it is important to remember that virulence is more a habit of a germ than an integral part of it, and can be gained or lost by a germ in accommodating itself to the surroundings in which that germ is placed. To illustrate: The streptococcus pyogenes may be taken from a very virulent case of sepsis and inoculated on agar. Much difficulty may be experienced in getting it to grow, for the germ may have very thoroughly accommodated itself to growing inside the body, and to grow on dead matter or as a saprophpte requires a change of habit. Some of the individual germs of the culture, however, will be able to adapt themselves to the new conditions and these will produce others like themselves, and each succeeding inoculation will grow more easily until by a sort of hereditary selection the germ has completely changed its habit. If some of the germs had been inoculated directly from the case of sepsis to an animal, death would have surely followed; but if now we inoculate some of these same germs which have had to grow outside of the body for several weeks, we find that in so growing they have lost their ability to grow as a disease producer. They have ceased to be virulent. This virulence is lost gradually, and the longer the germ has had to live as a saprophyte, the more complete is the loss of virulence.

Now most of the bacteria occurring in the air or in the houses inhabited by healthy people are either by nature saprophytes or else have lost their habit of virulence to a greater or less extent; while those coming directly from an infection have this habit of virulence strongly on them, and we should be very careful to keep them where they can do no harm. But virulence is relative, and a but slightly virulent germ may produce infection if present in sufficient numbers or in an individual whose immunity is below par. As we have seen, the presence of the toxin of one germ paralyzes chemiotaxis against another germ, and in a sluggish condition of the intestinal tract we have a fruitful source of autointoxication, thus lowering general immunity; and it is for this reason that a saline or mercurial evacuant is so useful in the beginning of any infectious disease or when wound infection is feared. The inhalation of sewer gas has a paralyzing effect on the leucocytes, and it is from this diminished immunity rather than from any germs that are inhaled that people living in badly trapped houses are subject to infectious diseases. The presence of one germ or its ptomain, although both by themselves be harmless, often greatly increases the virulence of a pathogenic organism, and it is for this reason that mixed infections in phthisis and diphtheria are of more grave prognosis, and the reason why laboratory experiments and bedside experiences so often give different results is that mixed infection is present almost always in clinical work and never in laboratory experiments.

As to antiseptics and disinfectants in surgery, let me say in a general way that all disinfectants that we use act as irritants to protoplasm, and only as irritants to protoplasm; that bacterial protoplasm is as a rule more resistant to their action than the protoplasm of the animal tissues; that a non-irritant germicide has yet to be discovered; that inside the body and on clean open wounds much more harm than good is done by using germicides. It is impossible by any means short of the use of the cautery to kill all the bacteria in a wound, for all our agents act by combining with albumin, and the germ albumin is always present in much smaller quantities than the tissue albumin, and the distribution of the disinfectant is not selective but *pro rata*. In using such a disinfectant we kill, say, ninety per cent. of the germs, and in so doing prepare a layer of dead, non-resistant tissue for the remaining ten per cent. to grow on, and the germs we have left are able to grow faster in this unresisting location and do more harm than the one hundred per cent. could have done in healthy tissue with good resisting-power. It is a known fact that we can inject large numbers of virulent pus cocci into the uninjured peritoneal cavity and with no infection, but if an irritant be injected with them, or if the peritoneum be injured, or even if blood be injected at the same time, fatal peritonitis results. The best plan, then, is to use disfectants as strong as need be to render aseptic all substances which come in contact with the wound; to use fairly strong antiseptics in cleansing the skin of patient, but when it comes to the wound itself to use as little besides sterile salt solution as possible. The foregoing remarks apply to a clean-cut wound and not to a wound in which the vital resistance of the tissues has been already lowered by bruising or previous infection, for in this case we have already lost the vital resistance and no harm will be done by attacking the germ vigorously. To put the point more plainly, let us be sure when interfering in this struggle between the human system and the germ that in striking a blow at the germ we do not strike the system a more disabling one. Antiseptics in the intestinal tract are under somewhat the same conditions as those used in skin disinfection, and there is some reason to believe that very slightly soluble substances may be used with benefit in intestinal antisepsis. As to the treatment of the throat in diphtheria, the membrane should be kept removed, for it is the source and the only source from which the toxin comes, but the membrane should be removed by some agent which attacks dead matter and does not irritate living tissue. Such agents we possess in the digestive ferments, such as papain and trypsin.

Recent experiments have proven that the vaginal mucus of healthy women has a very marked action in destroying pathogenic and pyogenic bacteria, thus rather arguing against the too frequent use of the douche in the puerperal state, and the above fact may explain the success our gynæcologists are having in their operations.

The thermal death point of the gonococcus is quite low, a temperature of 40° C. (104° F.) killing it in a short time on media, and it is probably partly for this reason that urethral irrigations are so useful when given as hot as can be well endured. Other reasons might be cited to explain the success of hot irrigations, namely, that the action of most chemical disinfectants is greater in hot solutions, and that heat is useful in most inflammatory conditions, whether in-

fectious ones or not. On the other hand, it might be stated that a man with gonorrhœa may suffer from a fever of 105° F. or over and the gonorrhœa persist, although the discharge is usually lessened thereby.

Before leaving the subject of disinfectants, a plea should be made for more sunlight. Direct sunlight is probably as good a disinfectant as 1 to 2,000 bichloride, and it acts at low temperatures.

A new avenue for error has been recently discovered in searching for the tubercle bacillus in urine. It depends on the fact that the smegma bacillus, which frequently finds access to the urine, stains capriciously, and frequently cannot by any staining peculiarity be distinguished from the tubercle bacillus. The error may be minimized by rendering the meatus as clean as possible and then examining the urine drawn through a clean catheter.

The tetanus bacillus is known to be unable to grow in the presence of oxygen. Its spores are often found in the earth, and it is for this reason that a punctured wound produced by something which has been in the soil (as a rusty nail) is so apt to produce tetanus.

The micrococcus lanceolatus can produce pneumonia only when it gets down to the air vesicles. It cannot reach there if the cilia lining the respiratory tract are in good condition; but chilling and cold air paralyze ciliary motion, and it is somewhat for this reason that pneumonia follows exposure to cold, and especially breathing very cold air through the mouth. In speaking of diphtheria, I may say that its antitoxic treatment has almost passed out of the hands of the bacteriologist and belongs now to the clinician. I may say, though, that a sufficient number of units should always be used (rarely less than fifteen hundred), and these in as concentrated a serum as is obtainable. Much time can often be saved in the diagnosis by an examination of a cover-glass preparation from the throat, and the technique is very simple.

As to the antitoxic treatment of pulmonary tuberculosis it may be said that there are greater difficulties in the way than in diphtheria. Tuberculosis is not a local disease, and the bacilli occur in little patches or tubercles. Each of these is walled in to some extent by fibroid or necrotic tissue. Now, when the antitoxin is used, the toxin is neutralized and the symptoms improve; but the walls of the tubercle prevent the phagocytes from getting in to attack the bacilli and so they are not destroyed, and when the antitoxin is stopped their toxin is no longer unneutralized and the symptoms recur. In miliary tuberculosis these tubercles are not so thick-walled and many of the bacilli are not in tubercles, and in this disease antitoxin seems to be somewhat more beneficial. Perhaps when tubercle antitoxin is improved and its antitoxic strength is more often definitely stated in units, we may use it with more success.

Considerable help can be obtained in infectious diseases by a cover-glass preparation of the blood. Malaria will of course be recognized, and a study of the degree of leucocytosis present aids as much in prognosis.

The blood test for typhoid is attracting much attention just now. It depends on the fact that when but slightly virulent typhoid bacilli from a culture tube are placed in some blood serum from a case of true typhoid fever they lose their motility and tend to cling together in clumps, or agglutinate. While typhoid serum has this property to a greater extent than other blood serum, serum in the normal individual and in some other diseases possesses the property to a lesser degree, and to make sure the case is typhoid it seems necessary to dilute the serum in the proportion of sixteen to one and to form our opinion from the reaction under these conditions of dilution. The reaction is not usually elicited until the disease has been present some days, and dried blood does not seem to give the same satisfaction as does the diluted serum.

SURGICAL CASES IN GENERAL PRACTICE.[1]

By G. W. KING, M.D.,

HELENA, MONT.

Case I.—J. P——, miner, aged thirty-five, fell a distance of twenty feet, his head coming in contact with a stull (timber) in the descent. The only visible signs of external injury were found to be a scalp wound, one and one-half inches in length, beginning one-half inch to the right and the same distance below the occipital protuberance. No evidence of fracture could be found. The symptoms of profound shock were present; the patient being unconscious, with moderately dilated pupils, muscular relaxation, irregular respiration, coldness of extremities, etc. The treatment adopted was that for shock in general, viz., warmth to the extremities and epigastrium, hypodermic injections of strychnine repeated according to indications. Reaction came on slowly twenty-four hours later; consciousness returned, followed by rapid improvement in all the symptoms; and at the end of the seventh day there remained no appreciable signs of intracranial injury. The case was kept under observation, and the possible dangers that might result from imprudence on his part were fully explained to the patient. On the twenty-second day after the injury there was a sudden onset of symptoms pointing to severe cerebral complication; the temperature was 101° F., with great disturbance of the sensorium, which soon merged into a condition of coma. On the following day a trephine opening was made at the site of the injury, the dura was incised, and a careful exploration of the underlying portion of the brain was made with an exploring needle. Nothing definite was learned from this source, and as the condition of the patient did not permit of further search the operation had to be abandoned without discovery of the lesion. There were encouraging symptoms immediately following the operation, consciousness returned, the temperature fell to the normal. This apparent relief, however, proved to be but temporary, continuing about fourteen hours, when coma again supervened and death occurred the next day. It is much to be regretted that an autopsy could not be obtained to demonstrate the location and nature of the lesion. Doubtless the relief obtained was due to the lessening of intracranial tension, and possibly had the skull been opened at another point permanent good might have been accomplished.

These cases are instructive, inasmuch as the question of trephining in the absence of localizing symptoms is a debatable one. The indications of brain lesions following head injuries are in many instances too obscure to be of any value as to the exact location of the trouble; hence the operator should be prepared to make one or several openings in the skull if necessary.

Case II.—J. W——, farmer, aged sixty-two, received contusions of the frontal bone by accidentally falling against the edge of an open door. The scalp being uninjured, little attention was given to the injury at the time. Subsequently a swelling appeared over the bruised area, gradually increasing in size; but, accompanied by little if any pain, it was still neglected until it had reached dimensions sufficient to cause anxiety as to its nature. When he presented himself for treatment, the appearance of the swelling, to-

[1] Read at a meeting of the Montana State Medical Association, Helena, April, 1896.

gether with the history of a contusion, made the diagnosis of abscess with probable necrosis of the outer layer of the frontal bone the correct one. The abscess was evacuated and the conditions were found as anticipated. The wound was dressed and the patient put

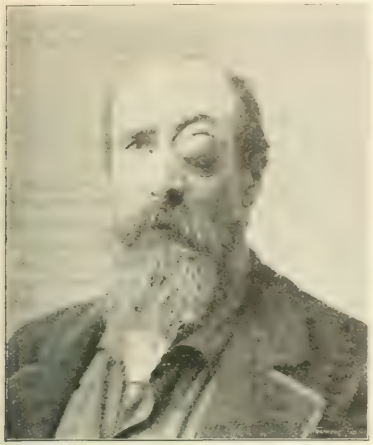

Fig. 1.

upon the "mixed treatment" as a tentative measure. It was impossible to carry out direct and continuous treatment, as the case could be seen only at irregular intervals. Three months later a free opening was made in the scalp, revealing a large cavity in the outer layer of the frontal bone. The incision was kept open by gauze packing, and time allowed for exfoliation of the necrosed bone tissue. The administration of iodides was, however, continued. As there were no symptoms of involvement of the dura, nothing further was attempted. The slow progress of the disease being recognized, it was hoped that separation of the necrosed bone would eventually take place.

Nothing worthy of comment occurred until the early part of January, 1896, some six months later, when summons was received to visit the patient immediately, as he had suddenly become insane and could with difficulty be controlled. The case did indeed look unpromising. The history of the attack as stated by those present was that upon the evening previous, without apparent cause, he had become delirious; he became unable to recognize members of his own family, constantly endeavored to get down upon the floor in search of imaginary objects, and was very restless. There was no paralysis of speech or motion. Examination of the necrosed portion of the skull showed that the disease had progressed with probable infection within the cranial cavity. As soon as arrangements could be made for operation, the trephine was applied and an abscess opened between the inner and outer tables; the opening was enlarged with the rongeur forceps, and all of the diseased bone removed. The dura was not incised, as it presented no evidence of being invaded by the disease process. The large cavity remaining was packed with gauze and the patient put to bed. The immediate effect of the operation was a subsidence of the extreme irritation, the patient being quiet, though his intellect remained clouded. The wound progressed favorably and his general condition improved rapidly. Moderate doses of iodides had been used from the beginning. It was now decided to try larger doses; accordingly sixty grains three times daily was ordered. The beneficial results of this plan of treatment were soon apparent, and at the present time the patient is relieved of the cerebral complication and is in a fair way to recovery. The prognosis is of course a matter which time alone can demonstrate.

Case III.—Prospector, aged fifty-four, of dissolute habits, came in from the hills for treatment of a dropsical effusion in the lower extremities. The effusion was found to be due to an attack of nephritis, from which he recovered in due time. The left eye had been sightless for ten years, with no history as to the cause. Some months later he consulted me for what he supposed was an inflammation of the lower lid of the unsound eye. The appearance of the part was not unlike that of a case of aggravated trachoma. Treatment was directed toward allaying the irritation, but without producing the slightest effect. It soon became evident that there was something more than simple inflammation to deal with. The rapid increase of the growth, its general appearance and location, left little doubt as to its malignant nature. Within two months from the time of the first inspection it had attained the size shown in the illustration (Fig. 1) here presented. Incidentally it may be mentioned that a medium-sized lipoma situated in the occipital region had been growing for a long time. The accompanying illustration (Fig. 2) defines its situation and appearance. Both tumors were removed at one operation, for the lipoma a simple excision only being necessary. The removal of the orbital tumor required more care; the eye was enucleated, and with it the contents of the orbit. Hemorrhage was of course very free, but easily controlled by packing. Figs. 3 and 4 represent the patient as he appeared six weeks after the operation.

An interval of quiescence followed the removal of the orbital tumor, but, as the sequel proved, the operation was by no means curative. Recurrence is the rule with sarcoma, especially that of the melanotic variety. The complete removal of all infected tissues within the orbit is very difficult, if not impossible. The astonishing rapidity which characterizes the secondary growths in this form of sarcoma is their most distinctive feature. In the after-treatment of the case strict attention was given to cleanliness, and the application of arsenical paste was made to all suspicious

Fig. 2.

points. Notwithstanding these precautions, the disease appeared in the upper angle of the orbit and steadily advanced until the growth had reached one-half its former size, when a second operation was undertaken and thorough removal again effected. The

upper eyelid was included in the growth. This procedure served to hold the disease in check for a limited time only. Its next appearance was in the lower part of the orbit and its growth was progressive. For a third time the knife was applied and all visible por-

Fig. 3.

tions of the tumor were taken away. The after-treatment was careful and thorough, yet unavailing. Opportunity was taken to try some of the stronger caustics —chromic acid and hydrofluoric acid; the latter gave the best results. It was used with caution, the most prominent parts of the tumor being merely touched with a glass rod previously dipped in the acid. Evidence of general infection was now unmistakable, the patient's nutrition became defective, and he lost strength rapidly. All attempts to do more than relieve the most urgent symptoms were abandoned. The actual cautery had been tried during the progress of the case. The patient lingered in this condition for two months, finally yielding to the inevitable one year from the date of the first operation.

From the experience gained in the treatment of this case, I believe that in attacking like tumors all the soft tissues surrounding the orbit should be removed without regard to cosmetic results, which are but secondary considerations when we are dealing with a disease so formidable.

Case IV.—Atheromatous tumor of the scalp. This case is cited, not that it possesses any features of special interest, but rather as a record of the successful use of the infiltration method for securing local anæsthesia. The tumor was of considerable size. The following formula was used:

℞ Muriate of cocaine	gr. ss.
Muriate of morphine	gt. ½s.
Chloride of sodium	gr. i.
Distilled water	℥i.

About thirty minims was injected in the line of the proposed incision. No pain was experienced during the operation, including the placing of the sutures. This method seems to be safe and efficient, and is therefore recommended for further trial.

Cases V. and VI.—At a former meeting (1894) I presented to the association a patient upon whom I had operated for the radical cure of hernia. When last examined, some three months since, the parts were found in good condition, firm and solid. He wears no truss, is doing heavy work without any inconvenience whatever. At this time I have two more cases to record. A carpenter, aged thirty-five years, had left inguinal hernia of fifteen years' standing; it was imperfectly controlled by a truss, hence a constant menace to life from danger of strangulation. By an incision over the inguinal canal the inner ring was exposed and then closed as nearly as possible with kangaroo-tendon sutures. Primary union followed.

The second case: Prospector, aged fifty-four years, had recent double inguinal hernia complicated upon the right side by hydrocele. The hydrocele was treated by incision and the hernia of the same side operated upon in the usual manner. The result has been good; the only thing to be regretted was the use of silkworm gut for the buried sutures, which subsequently caused so much irritation as to necessitate removal.

Before leaving the subject a brief reference to two cases of strangulated hernia may be of interest at this time—the one neglected and in a hopeless condition; the other seen early and amenable to treatment. When one is familiar with the operation for hernia it is always an unpleasant experience to be confronted with conditions like these: An elderly man with reducible hernia of many years' duration, after a prolonged debauch, during which it became strangulated, at the last moment called the physician. The strangulation had existed seven days and the patient was of course beyond surgical aid. An incision over the tumor revealed a gangrenous and sloughing gut. It was seen at a glance that nothing further could be done, and the patient died a few hours later. The other case illustrates a plan of treatment which, while not always safe to pursue, may under favorable circumstances be adopted: Middle-aged man, right inguinal hernia retained by a truss. Having returned home late one night, he removed the truss and the hernia slipped down. Being unable to return it in the accustomed way, he sent immediately for assistance. Not being an advocate of taxis except to a limited extent, and finding that the tumor did not yield to careful manipulation, I decided to elevate the hips and give a hypodermic injection of morphine, as no very urgent symptoms were present. The patient was informed that an operation would be necessary in the morning, provided the intestine had not returned. Upon the morning visit it was found

Fig. 4.

that under the relaxing effects of the morphine aided by position the hernia had become replaced with ease. Probably had the necessary assistance been at hand, the operation would have been performed at the first visit. There is no doubt that many cases could be

successfully treated in this way, if forcible attempts at reduction were avoided. The irritation caused by rough handling adds to the difficulties of the case. Palliative measures should not be persisted in if after a reasonable time it should appear that no progress is being made. Under such circumstances there is but one thing to do—operate, close up the internal ring, and cure the patient.

Case VII.—Epithelioma of scrotum and penis. Miner, aged forty years, first noticed a small sore on the outer side of the foreskin, gradually increasing in size without induration or swelling. Some weeks later a similar sore appeared upon the right side of the scrotum. At this time he presented himself for treatment. There was no history of venereal infection. An accurate diagnosis could not be made from the appearance of the parts. No enlargement of the inguinal glands could be discovered. Local treatment was applied and the patient put upon specific remedies as a test. No improvement followed; on the contrary, the disease steadily advanced. The health of the patient remained good. Several weeks were spent in vain endeavors to bring about healing of the sores. At this time the peculiar appearance of the one situated upon

Fig. 5.

the scrotum created the suspicion of epithelioma. A section was placed under the microscope and the suspicion verified. No time was lost in removing a portion of the scrotum, going wide of the disease. Circumcision was also performed, sufficient tissue being taken to guard against recurrence. The parts healed perfectly, leaving no trace of the growth; and up to the present time the patient has remained well.

Cases VIII. and IX.—Talipes equino-varus. The treatment of talipes is occasionally forced upon the physician. While it is true that these cases are perhaps better cared for in institutions devoted to that branch of surgery, much may be done and quite satisfactory results obtained, if the requisite time and patience can be secured. To illustrate the method and results of treatment the following cases are cited:

A boy, aged seven, for congenital talipes equino-varus had received treatment from infancy, but probably had not been kept strictly under medical supervision. He was wearing heavy steel braces entirely unsuited to the case. His feet were tender from the excoriations caused by pressure of the instruments over the bony points. Indeed it was with the greatest difficulty that he could walk at all. The deformity was such that the weight of the body was thrown upon the outer side of the foot, with the heel drawn up by the contracted tendons (Fig. 5). Under anæsthesia tenotomy of the

Fig. 6.

Achilles tendons of both feet was done, and plaster-of-Paris dressing applied while the feet were held in an overcorrected position. After the tendons had healed a Scarpa's shoe was adjusted and worn until the patient was able to control his limbs sufficiently to wear an ordinary shoe well stiffened at the ankles (Fig. 6). The after-treatment in this case was faithfully carried out by the parents and materially aided in the result.

Girl, aged six years, had congenital talipes equino-varus, more aggravated in type than in the preceding case; she was walking upon the dorsum of the feet. The accompanying illustration (Fig. 7) indicates the position. Attempts had been made to correct the deformity without operation, but as a matter of course had failed to influence it in any degree, and owing to the pain and discomfort attending this treatment it had been abandoned. Evidently the first step in the treatment was the division of the contracted tendons. Accordingly tenotomy of the Achilles tendon with a thor-

Fig. 7.

ough division of all the tendons and fascia upon the inner side of the foot by open incision was the opera-

tion chosen. The corrected position was maintained by plaster-of-Paris dressing. The wounds healed without suppuration. The plaster dressing was followed by the Scarpa's shoe at the proper time. This treatment was continued as in the other case, with the result shown in the illustration (Fig. 8). Since that time there has been some degree of relapse in the left foot due to neglect of the parents in supplying her with proper shoes.

Case X.—Necrosis of the crest of the ilium. This history is valuable, illustrating as it does the ineffective employment of medicinal treatment under a mistaken

Fig. 8.

diagnosis in a case strictly surgical: A man who formerly had been a miner, aged forty-five years, complained of shifting pains in the back, radiating from the left hip and extending down the thigh. There was no local tenderness, but there was some stiffness of the muscles of the back when he attempted to arise. Nothing abnormal could be discovered in connection with the heart, lungs, kidneys, or abdominal viscera. The diagnosis of rheumatism had been made and the patient put upon antirheumatic treatment. Taking into consideration the frequency with which miners past middle life contract rheumatism, and also the symptoms and history presented in this instance, it is quite probable that had he been examined by one hundred physicians there would have been no dissenting opinion. The futility of medicinal treatment was perplexing, for it is usually possible to alleviate if we fail to cure. The patient visited the Hot Springs in the hope of obtaining relief from the constant pain, but without success. During the following months but little change took place in his condition. Treatment was discontinued and the case passed from observation for the time. When next seen he was confined to bed and had a temperature of 102° F. A large circumscribed swelling had appeared at the left of the spinal column, about the level of the last dorsal vertebra. Fluctuation being present, an incision was made over the tumor and a quantity of pus evacuated. Relief of pain was immediate. By the use of a probe search was made for diseased bone. After prolonged effort the location of the trouble was found to be at the posterior part of the crest of the ilium. Free discharge from the abscess cavity took place, eventually forming a sinus which continued to discharge for six months. An operation had been suggested from the first but had been persistently refused. Seeing no prospect of permanent relief without it, he at last consented. Free incision was made and a thorough removal of the necrosed bone accomplished. Prompt and satisfactory healing took place, and in a few weeks the patient was discharged cured.

Remarks.—The cases herewith submitted are but a type of those constantly coming within the observation of the busy practitioner. What shall we do with them? In the larger cities the physician can refer them to the hospital surgeon without assuming the responsibility of treatment. In the field which we occupy this cannot be done, and we are forced to recognize the fact that medicine and surgery are so inseparably connected in actual practice that he who would be the most successful in the future must acquire a fair facility in operative work. The question of what to do in a given case is not more important than how it is to be done. Generalization will not do; a definite plan of procedure must characterize every operation, no matter how trivial. To choose the best methods from the vast amount of surgical literature available is not always possible, as in emergencies when action must necessarily take the precedence. What surgical knowledge we possss must therefore be practical. I am aware that our opportunities for perfecting technical skill are limited, but if we choose to employ a portion of our leisure moments in training the hands to familiarity with the use of instruments, we shall become something more than mere "bunglers" in the art of operating. The progress in surgery which marks the present era has in no wise limited the field of the general practitioner. It has, on the contrary, enlarged it by enabling him to become more proficient by being more scientific in his attainments and consequently more successful in practice. To undertake the treatment of surgical cases is not a matter of choice but a necessity. The care of wounds and all the various injuries that may occur are but part of our daily duties. The only limit which the true physician is compelled to recognize is that which exists in his own ability to observe, to investigate, to acquire.

THE NEED OF INSPECTION OF THE EYES OF THE CHILDREN IN THE NEW YORK PUBLIC SCHOOLS.

By WILLIAM MERLE D'AUBIGNÉ CARHART, M.D.,

NEW YORK,

ASSISTANT SURGEON, MANHATTAN EYE AND EAR HOSPITAL; INSTRUCTOR IN DISEASES OF THE EYE AND EAR IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL; OPHTHALMIC AND AURAL SURGEON, BELLING HAND HOSPITAL, BROOKSIDE, N. Y.

The accompanying figures, showing the percentages of ages of one thousand school children recently examined by me, are suggestive. Two factors are probably operative in causing this steady decrease in attendance from the 24.1 per cent. of the ages of eleven to twelve, to the 2.4 per cent. of the ages of seventeen to eighteen. Some children are withdrawn from school to assist in supporting the family, and the parents of many others are indifferent about graduation, thinking the advanced grades not essential for the success in life of their offspring. This factor applies, however, mainly to the older scholars, while my figures show that children begin to drop out before they are old enough to become wage earners and long before they have reached the advanced grades.

Attendance by ages of one thousand school children: From five to ten, 42.3 per cent.; eleven to twelve, 24.1 per cent.; thirteen to fourteen, 19.5 per cent.; fifteen to sixteen, 11.7 per cent.: seventeen to eighteen, 2.4 per cent.: total, 100 per cent.

Children leave school in many instances because high refractive error makes study unendurable for them. Attention to lessons and close application to study are difficult, if not impossible, when there is

any considerable refractive error left uncorrected in the eyes. When we see a healthy boy or girl, bright and active on the playground, but restless, inattentive, and careless in the schoolroom, we may be confident that the child has imperfect eyes. Such children cannot concentrate their attention on their books for any length of time, in consequence of the strain upon the ciliary muscle in the effort to maintain visual acuity. They are apt to be called stupid and lazy when they fall behind in their studies, and because they are bright and quick about everything except their lessons they may be considered mischievous and bad. Often the condition of the eyes is not brought to the notice of either teacher or parent, since not all such children complain of supra-orbital headache. Many of them merely feel tired and listless after school hours, and are restless and inattentive while at school.

Children are markedly tolerant of refractive error. During my school examination I found many cases of children struggling along without glasses, when the Javal ophthalmometer showed several diopters of astigmatism; and also not a few who were wearing lenses for nearsightedness when they were really not myopic at all—a condition of affairs which no adult could endure for a day. But tolerance is not immunity. Every such case presented a striking picture to the ophthalmoscope: a retina covered with dilated blood-vessels and congested over its entire area; an optic disc infiltrated and swollen so that its outline was indistinct and its color grayish; and surrounding the disc a conus, broad and deep, through which the sclerotic tissue could be seen to share in the general congestive infiltration. Externally many children showed congestion of the palpebral and bulbar conjunctiva, with blepharitis marginalis, and subjectively photophobia and asthenopia were not uncommon.

These children suffer from congestion and infiltration of the eye and its appendages, due to continual strain of accommodation at close work. The soft and elastic tissues of the immature eye of childhood yield gradually both at the posterior pole and at the anterior surface, and so we find, in addition to symptoms of retinal irritation, an alteration of structure, which results in the lengthening of the optic axis and the development of corneal astigmatism. I have elsewhere[1] given statistical tables of the refraction of one thousand school children, and I will here merely refer to three significant items. Astigmatism of all varieties increased, from 35.65 per cent. at the ages of five to eight, to 61.69 per cent. at the ages of thirteen to eighteen. Myopia and compound myopic astigmatism combined increased, from 2.61 per cent. at the ages of five to eight, to 6.43 per cent. at the ages of thirteen to eighteen. Hypermetropia decreased, from 53.48 per cent. at the ages of five to eight, to 22.81 per cent. at the ages of thirteen to eighteen. Space does not permit further reference, but even the three citations I have made will prove the elongation of the eyeball and the alteration of the curve of the cornea caused by distention.

Dr. Ingalls has said: "It is a waste of time to send a child to school when his eyes are not in proper condition to do the work assigned." More than that, permanent injury to the eyesight is the penalty of the violation of nature's laws. Not only is the existing refractive error aggravated by the efforts of the child to keep up with his more fortunate comrades, but inflammatory and degenerative changes are easily engrafted upon retinal irritation if the strain is persistent. Many a child also is urged beyond his physical limitations, until his health gives way in a general nervous collapse. A high authority has said that "eye strain in childhood means neurasthenia in the adult." This is certainly true in many instances.

[1] New York Medical Journal, April 17, 1897.

The schools have thus far been able to do little toward recognition of ocular defects, and so children, handicapped by high refractive error, have received much the same treatment as those with perfect eyes. Is it not a natural consequence that children begin to leave school at an early age and continue to drop out in ever-increasing numbers as they grow older? A beginning at school inspection has been recently made in several cities. Dr. Frank Allport, in the June number of the *Review of Reviews*, gave a description of the plan he has put into effect the past three years in the schools of Minneapolis. He has examined, with the help of the principals of the schools, 23,049 school children, among whom he found "7,093 defectives," the parents of whom were notified of the state of their children's eyes and advised accordingly. A somewhat similar plan has been carried out by Dr. Harlan and Dr. Wood, in the schools of Baltimore, where nearly 53,000 children were examined and 9,051 were found with abnormal vision. Recently the children in the schools of Bridgeport, Conn., were examined personally by my friend, Dr. Miles, with similar results; and one year ago I went over the public schools of Peekskill, the published tables of which examination I have already referred to in this article.

Problems of school inspection are of particular interest at the present time, since it is proposed to institute a thorough examination of the eyes of the children in the New York schools. The need is urgent, as I think I have shown, and now it remains for the greatest city on the continent to do this work intelligently, carefully, and scientifically. How this work will be done is a matter for consideration, but as an ophthalmoscopic examination of the eye is essential for any accurate knowledge of its condition, it would seem hardly feasible to utilize Dr. Allport's plan to any considerable extent in depending upon the assistance of the teachers of the schools.

It is neither desirable nor necessary that treatment be instituted by the proposed health-board inspectors, and therefore no elaborate refraction test rooms need be established. Cards of notification of ocular defect could be issued, and the necessary treatment would then properly be carried out by whatever oculist the family physician recommended. In this way there need be no interference with the practice of our professional brethren, and little temptation for the inspectors to attempt to build up a private clientèle. In order further to avoid unpleasant complications and also to save time, it might be well to omit any children who had been within one or two years under the care of any competent oculist. The number of school children in New York is enormous, but a corps of twenty inspectors should be able to cover the ground in two years, according to my estimate, and of course all could be examined within the year by double that number of inspectors if such a course were deemed necessary.

GUAIACOL IN CHRONIC COUGHS.

BY ADOLPH GOLDHAMMER, M.D.,

ALTHOUGH guaiacol is recognized as a valuable antituberculous remedy, its value in the treatment of chronic coughs of various character is not so well established. Having had remarkable success with this drug in many cases of cough of long standing, in which no tuberculous element could be recognized, I venture to suggest its use in every case of cough of more than two weeks' duration.

I was first led to the employment of this remedy in a case in which the cough had existed for two years and in which numerous other drugs had been used without avail. Under the use of guaiacol daily for one month, the cough disappeared and the patient has been entirely free from it ever since—a period of ten months. The details of this case will be described farther on. Since then I have used guaiacol in every case of cough of more than two weeks' duration, irrespective of origin, with unvarying success. I have found it of decided value in cases of chronic bronchitis with or without asthma. In the chronic coughs of children guaiacol has proved especially beneficial. I have employed it even in several cases of whooping-cough with astonishing results. The paroxysms were rendered less severe and less numerous, and the duration of the attack was cut short to two or three weeks. For children of a delicate temperament, who have a poor appetite and who occasionally have a slight cough, guaiacol is a very valuable remedy. It stops the cough entirely in a short time, increases the appetite, and causes the patient to gain flesh. It is my opinion that many a case of incipient tuberculosis could be prevented, if every old cough, no matter how slight, were treated by the administration of guaiacol. I therefore strongly recommend it as a prophylactic against tuberculosis; but I desire especially to emphasize the fact that guaiacol is of immense benefit in cases of cough, not acute, in which no tuberculous element exists. In acute coughs, guaiacol does not act beneficially and should not be employed. I have carefully recorded thirty cases of cough of varied origin and description, in which no distinct tuberculous element could be recognized, and in which I employed guaiacol as a remedy. In twenty-six of these cases the cough disappeared entirely after the drug was used for periods of from two to six weeks. In the four remaining cases the cough was decidedly improved, although not entirely cured. Eighteen of these cases were in children under ten years, nine were in adults, three of whom were over sixty-five years of age. The details of a few of these cases follow.

CASE I.—Mrs. H——, aged sixty-two years. The patient's appearance was quite robust and her color good. She had been coughing for about two years almost every day. She very frequently had severe coughing-spells during the night. Sometimes with the coughing-spells she had severe pain in the back and over the sternum. Her appetite was fairly good; she never sweated in the afternoon; she had never spit up any blood. Her pulse was 72; respiration, 26; temperature, 98.6° F. She suffered from dyspnœa on going up or down the stairs. Physical examination showed the breathing somewhat loud, with the expiration somewhat prolonged and sibilant, and sonorous râles. Percussion gave a hyperresonant note. I diagnosed the case as one of chronic bronchitis with asthma. She told me that she had been treated by many different physicians and had taken all sorts of cough mixtures, sometimes with temporary improvement, but had received permanent relief from none. It was in this case that I first determined to try guaiacol. She began by taking five drops three times a day, in milk, the dose being gradually increased until she took twelve drops three times a day, at the end of three weeks. She noticed decided improvement in her cough after she had been taking the drops for four days; in ten days the cough was very slight and not troublesome; at the end of four weeks the cough stopped entirely and has not reappeared now for ten months.

CASE II.—L. M——, aged twenty-eight months. The mother informed me that the child had had an attack of whooping-cough when eighteen months old and had been coughing more or less since. The appetite was not good and the child was kept awake much at night by the cough. I found signs of chronic bronchitis on examination. I administered guaiacol, beginning with two drops and increasing to four drops, three times daily. At the end of two weeks the cough had entirely disappeared, the child slept well and began to look much healthier, and gained flesh. The child has coughed very little since.

CASE III.—Sidney R——, aged eight years. He had always been a delicate child and his appetite was never very good. Occasionally he had slight coughing-spells; sometimes he coughed very severely. His mother said that the cough had lasted several years. On examination I found that he was chicken breasted, but otherwise there was nothing to account for the cough. He took guaiacol for six weeks, beginning with three drops, gradually increased to seven drops thrice daily. He also took wine and cod-liver oil. His cough disappeared entirely, his color is now ruddy, and altogether he is much livelier and brighter than he used to be.

CASE IV.—Mr. M. G——, aged seventy-one years. For many years he had been suffering from a severe chronic bronchitis with frequent very distressing asthmatic attacks. He had taken many medicines, but he said that they always made him worse and sometimes they nearly choked him. Finally he refused to take any medicine whatever, although he suffered severely, and I had to use much persuasion to get him to try guaiacol. After he had taken the drug for a week his cough was immensely relieved and the asthmatic attacks were not so frequent and severe. The old gentleman is so delighted with the remedy that he now absolutely refuses to stop taking the "devil's drops," as he calls them, on account of the taste I suppose. He still coughs a little, but his cough is slight and not troublesome.

CASE V.—Sadie D——, aged six years. This patient had an ordinary attack of whooping-cough. During the first week I gave her tincture of belladonna and quinine, the drugs I ordinarily employ in such cases. There was not much improvement, and she had severe paroxysms of coughing and vomited frequently. During the second week I thought I would try guaiacol, and I was much astonished at the result. The cough improved very much after two days' use of this drug and after seventeen days there was no sign of the cough left, although I had used no other drug than guaiacol.

As regards the administration of guaiacol, it is very well borne in the majority of cases, if well diluted with milk, although it has a nasty taste. It very seldom deranges the digestion. Those who cannot bear its odor or taste can easily take it in capsules. I usually begin by giving five drops three times a day, in milk, to an adult. The dose may then be increased one drop daily up to fifteen drops three times a day. A child one year old can take two drops at a dose to start with, and then the dose may be increased slowly to four or five drops.

Progress of Medical Science.

The Treatment of Tuberculosis with Tuberculin.—Spengler (*Deutsche medicinische Wochenschrift*, No. 36, 1897) makes an interesting contribution to the subject of the treatment of tuberculosis with Koch's new product. He states that tuberculin has never been entirely discarded at Davos since it was first used nearly seven years ago. He now relates his later experiences with the present modification. There were treated with tuberculin fifty-nine patients, twenty, however, only from three to seven weeks, in the absence of colleagues under whose care they were. The whole number received nine hundred and twenty-two injections, with a total of one hundred and eighty-one cubic centimetres. In not a single instance was an untoward effect noted, although at times there was pronounced reaction. All cases of tuberculosis in which fever was absent were considered suitable for treatment; that is, those in which the rectal temperature did not exceed 37.5° C. (99.5° F.) and the temperature of the mouth 37.2° C. (99° F.). Axillary temperatures, especially in emaciated tuberculous subjects, cannot be relied upon unless the thermometer has been exposed for twenty minutes. Exceptionally, cases in which the rectal temperature exceeds 37.7° C. (99.9° F.) may be submitted to the treatment when careful examination of the sputum demonstrates the absence of marked mixed infection. The injections may be made from the initial dose up to one milligram every second day, in doses of from one to six milligrams every third day, in doses of six to twenty milligrams every fourth or fifth day. The latter dose may be reached if the remedy is well borne and its use is unattended with marked exhaustion and loss of weight or profound anæmia. Then, according to circumstances, from five to ten milligrams are administered weekly, and later every seven or ten days. When the larger doses are used, longer intervals are necessary, as the substance displays a sort of cumulative action. Intercurrent menstruation is not a contraindication for the continuance of the treatment. If hæmoptysis occurs the injections are temporarily suspended, subsequently beginning with a minimal dose, especially if the hemorrhage is accompanied by fever. Hæmoptysis occurs, however, with comparative rarity in conjunction with the use of tuberculin, the old as well as the new. The injections were made, so far as possible, on the extensor aspect of the forearms, for facility of observation. Should local swelling be marked, a longer time than usual should be permitted to elapse before the next injection is made, and great care should be exercised in regard to increasing the dose. If febrile reaction occurs, the dose should under no circumstances be increased. Temperature exacerbations of more than half a degree should be avoided. Should the febrile reaction continue for more than a day or two, the subsequent injection must be distinctly smaller than the previous one. Some patients appear so susceptible to the remedy as to be totally unsuited for the treatment with subcutaneous injections. In these the remedy may be employed by percutaneous introduction (by means of energetic friction upon the cleansed skin). Of the thirty-nine personal patients subjected to the treatment, not less than thirty had been under observation for six months and more; twenty-five were subjects of pulmonary tuberculosis, while in eleven others there was both pulmonary and laryngeal involvement. Of the latter seven had been considered cured before the institution of the new treatment. In six slight reddening of the cicatrices became evident only in conjunction with febrile reactions. In none was there any aggravation of the laryngeal condition, but in two, in whom the injections were repeated frequently during three months, there occurred diminution in the thickenings present in the mucous membrane of the larynx. In one case there was, in conjunction with the febrile reaction, complaint of slight pain referred to the cicatrix. Existing ulcers displayed only slight redness of their margins. The impression was gained that ulceration improved more rapidly under the combined treatment than under treatment with lactic acid alone. Just as the febrile reaction was less marked than after the use of the old tuberculin, so also was cough increased to a less degree and the local auscultatory phenomena were less pronounced. In all patients who had noteworthy expectoration striking and permanent diminution was observed. Under such conditions the impairment of resonance grew less, as did also the râles, and the physical signs of infiltration receded distinctly. No renal or intestinal complications were noted, although albumin was found in the urine in eight per cent. of the cases treated with the old tuberculin. In the case of a patient not entirely free from mixed infection the treatment was employed in view of the relatively low temperature (37.7°, 37.8° C. —99.9°, 100° F.), but it had soon to be interrupted, as it proved useless.

Rembold publishes, in the same journal, an analysis of eighty-two cases of pulmonary tuberculosis treated in 1890–91 with tuberculin. Of these, reports could be obtained concerning seventy. Of this number twenty-seven could now be recognized as being instances of mixed infection and thus unsuited for the treatment. All of these died—twenty-three during the first year following the treatment, two in the second, and two in the third. Of the remaining forty-three cases of unmixed tuberculosis, twelve were classified as severe, fifteen as of moderate severity, and sixteen as mild. Of the first, ten died in the course of the first four years following the termination of the treatment. Two were still living and permanently improved. Of the second group, seven died also during the first four years, and seven were living and permanently improved, while one was permanently cured. Of the third group, one had died in the fourth year, three were permanently improved, and twelve were permanently cured. Upon the basis of this experience the conclusion is expressed that in case of mixed infection tuberculin is without any favorable action; and that, while in cases of unmixed tuberculosis of the lungs little is to be hoped for in severe cases, marked and permanent improvement may be anticipated in many cases of moderate severity, and almost certainly good results, even to complete cure, in the mild cases.

Acute Yellow Atrophy of the Liver in a Girl Twelve Years Old.—In *The Lancet* for July 17, 1897, Fison reports the case of a girl, twelve years old, who three weeks before coming under observation had complained of general pains, lasting for three days and followed by what was thought to be a bilious attack, with vomiting after eating and headache. Jaundice had been present for ten days. There was no history of fright or mental shock. The jaundice was pronounced and the child appeared very ill. The temperature was 101.4° F., and the pulse 92. The tongue was coated. There was much bile in the urine, but none in the fæces. No physical abnormality of heart or lungs could be detected, but the liver appeared to be considerably enlarged. There was complaint of persistent pain in the right hypochondrium, with occasional nausea and impaired appetite. The jaundice varied greatly in intensity from day to day. In the course of a few days the temperature returned to normal, but the jaundice and the other symptoms remained the same. Several days later the liver appeared to be smaller, but the general condition was

unaltered. On the following day the child suddenly became drowsy and unable to perform any action or answer questions. The reflexes were not abolished, but urine and fæces were passed into the bed. The temperature was slightly above the normal; there was no delirium. In the course of a little while hemorrhages were noticed over the sacrum and convulsive movements took place in the arms, followed by rigidity. Coma now set in, and death took place sixty hours from the onset of the acute symptoms. No leucin or tyrosin was found in the urine. Upon post-mortem examination a number of subcutaneous petechial hemorrhages were found. The liver weighed three pounds and eight ounces and was flabby; the capsule was wrinkled, especially on the under surface of the right lobe. On section the substance of the organ was distinctly firm, of a light yellow-ochre tint, but free from red areas, although there were a few minute hemorrhagic patches. The lobules were indistinctly outlined. The gall bladder was filled with green bile mixed with an excess of mucus. The ducts were normal and unobstructed, but at the papillary orifice in the duodenum there were some slight inflammation and œdema, which prevented the ready expression of the bile. The portal vein was normal. The glands in the portal fissure were slightly enlarged. On microscopical section very few natural liver cells were seen, and they were full of granules. The liver tissue was to a great extent replaced by granular and fatty *débris* contained in a reticulated homogeneous nucleated structure, the nuclei probably being derived from liver cells. No leucin or tyrosin was observed. The capsule of the liver was slightly thickened. The pancreas was normal The spleen was greatly congested and rather soft. The kidneys weighed three and one-half ounces each; the cortex was pale. The adrenals were normal. The stomach contained altered blood and presented patches of submucous hemorrhage. The intestines also were the seat of a large number of submucous hemorrhages, especially in the cæcal region. The bladder was normal. The muscle of the uterus was bile stained. The brain weighed three pounds two ounces; the dura was bile stained and the brain tissue was normal. The lungs weighed eight ounces each, and presented a few subpleural petechial hemorrhages. They were œdematous and the larger bronchi contained muco-pus. Larynx, trachea, bronchial glands, and thyroid were all normal. The heart weighed one and one-half ounces; its muscular structure was bile stained, as was also the pericardial fluid; the valves were normal. The peritoneal cavity contained a considerable amount of bile-stained fluid: numerous subperitoneal hemorrhages were present, especially along the greater curvature of the stomach and in the great omentum.

Gastric Ulcer Perforating into the Pericardium.—Fenwick (*Lancet*, August 14, 1897) has reported the case of a man, fifty-five years old, who suddenly became ill and died within a few minutes. He had previously been in perfect health, and had not complained of pain after eating and had not suffered from vomiting or other symptom of disease of the stomach. After partaking of a meal consisting of tea, fish, and bread and butter, he arose from the table, complaining of pain and palpitation. After walking a few yards he sat down, and his wife, noticing that he looked very pale, administered some whiskey and water, but he expired in about a minute. Upon post-mortem examination the pericardium was found to contain several ounces of tea, which smelt of whiskey, together with some particles of fish. On the lower surface of the pericardium a small aperture was discovered, admitting a stout probe, which passed downward through the diaphragm into the abdominal cavity. The anterior surface of the stomach was firmly adherent to the under surface of the diaphragm, and on opening the viscus a chronic ulcer, almost one inch in diameter, with indurated edges, was seen to be situated about the centre of the lesser curvature. From the base of the ulcer a sinuous track led upward and to the right, through the substance of the pericardium. The stomach contained fourteen ounces of undigested material, composed of tea, fish, and sodden bread. The lungs were emphysematous, the right adherent to the chest wall. The heart was extensively infiltrated with fat; the valves were normal. All the other organs were apparently healthy.

A New and Easy Method of Examining Malarial Blood.—In a paper published in *The Lancet* of July 10, 1897, Macleod points out that for diagnostic purposes the examination of fresh malarial-blood films immediately after preparation is without doubt most to be relied upon. This is, however, not always convenient, and in a large practice it is often very inconvenient, so that one is driven to the examination of stained films at more convenient times. The staining of such films is an uncertain and troublesome process, so far as results that can be relied upon for diagnostic purposes are concerned. Macleod has succeeded in finding plasmodia in a preparation made by drawing across one cover glass the edge of another square cover charged with a drop of blood. He subsequently found that the same result could be effected by the use of a strip of ordinary notepaper, instead of the cover glass, for the purpose of spreading the film. The straight edge of a half-inch strip is drawn its full length through a drop of blood on the finger tip not larger than the head of a pin, the finger tip and the cover glass being previously cleansed thoroughly in the usual way. If too much blood be taken on the strip the film will be too thick and useless. The edge of the strip is quickly drawn across the cover glass, the strip being held nearly at right angles to the surface of the glass and before the blood has had time to dry upon the paper. In this way is spread on the cover glass (or slide if preferred) a fine film of blood which dries very quickly, and in it many excellent fields will be found, with the corpuscles lying on the flat and practically unaltered. The cover glass must not be fixed to the slide by any medium that will rub between the two, causing everything to disappear from view, but it must be mounted dry. It can be gummed to the slide by a strip of thin paper, with a window exposing the blood smear, when the latter can be examined with a dry or an immersion lens. With a good quarter-inch objective crescents and the larger pigmented parasites, and with an oil twelfth the smaller pigmented forms, can easily be seen. The specimens can be thus preserved and examined at any subsequent time, and even stained later. The film on a slide can be examined with a dry lens without the intervention of a cover glass; then stained, dried, and examined without a cover glass or with a cover glass with or without balsam. If an oil-immersion lens is used, the film when dried and unstained should be on the cover glass, as the layer of air between the cover glass and the slide, if the film is on the latter, prevents the oil working at its best. The films should be carefully protected from dust before they are mounted. The color of the protoplasm of the parasite is not quite the same dried as undried, and of course no movement of parasite or of pigment is possible in the dried state. Even the unpigmented parasites have been detected in the dried form as rings or signets, and they have been stained. Blood films treated in the manner outlined are subjected to less interference than when fixed by heat, alcohol, ether, or other means, or when treated with one or more staining solutions, washed, dried, etc.

THE EFFECTS OF CHANGE OF CLIMATE UPON MAN AND ANIMALS.

THE problems of the relations of climate to the health of man are varied and complicated. That environment does exercise a very strong influence on race is universally allowed, although we are still greatly in the dark as to its effects on the human organization. Much light has been brought to bear on the subject of climatology within recent years, it has been intelligently studied, and in consequence a more accurate knowledge is spreading of the influence of climate in regard to health and disease. Especially is this the case in relation to disease. Change of air is often as curious as it is beneficial in its effects. Extreme purity is naturally an important factor, but after all it is but one factor. In many instances it is by no means essential that a patient should go to the seaside or even to the country in search of health; a change in itself is often of the greatest benefit. It is related on good authority that a man suffering from asthma and bronchitis, who lived in a healthy part of the country, found great relief by residing for a time in the slums of Whitechapel. Change of climate has an even more powerful effect on animals than on man; in fact, man is the only animal that can adapt himself to any circumstance of life or meet any environment. Dr. Richard Newton, in a paper read before the American Climatological Society, gives the results of his observations on the effects of climate on men and animals at Fort Stanton, N. Mex., sixty-one hundred and fifty feet above sea level. His opportunities for study were limited, but, as he remarks: "The great need in the study of climatology at the present moment appears to be more investigation of individual cases, more ascertained and established facts in relation to the action of climatic changes upon people or animals." He describes the effect of the change of climate upon the fever-stricken Texan cattle, and points out that if they survive the winter, and when the disease germs are killed by the frost, they soon wonderfully improve and increase in weight. Horses suffer acutely when brought from the plains to high altitudes, and it is stated that it takes twelve months or even longer for them to become acclimatized. Dogs, as is well known, endure climatic changes better than any animal except man.

Dr. Newton's deductions as to the effect of change of climate on man agree in the main with those of other observers. He disagrees, however, with the view held by Dr. Solly, that high altitudes are inimical to rheumatism; his experience teaches the reverse. No one will dispute the point that change of climate is of benefit in phthisis, yet climate treatment of this disease is beset with many difficulties and needs to be applied with much discrimination. The rule may be laid down as one to be followed in most cases, that in the early stages of phthisis a sea voyage or journey to a distant clime will do good, but that when the progress of the disease is far advanced if a change be taken at all it should be limited. The fact, too, should not be forgotten that one of the most important *desiderata* for consumptive invalids is plenty of sunshine. The causes for the health-giving properties of a change of air are obscure; at any rate, up to the present they have not been satisfactorily explained. A biological solution of the problem is sometimes suggested, that as early man was of necessity a wanderer, these nomadic habits have left their impression upon every cell and fibre of his being, and thus it is largely a question of heredity.

THE COMPARATIVE INTELLECTUAL CAPACITY OF MEN AND WOMEN.

SIR WILLIAM TURNER, at the meeting of the British Medical Association at Montreal, once again brought forward the old assertion that because the brain of a man weighs absolutely more than that of a woman, therefore a man is possessed of a greater amount of brain power than is a woman. This theory until recent times was on all sides conceded to be true, and was regarded as a convincing proof of woman's intellectual inferiority. The Russian Professor Darkchevitch took up the cudgels in defence of the weaker sex, and demonstrated to the satisfaction of the majority that the fact of a man's brain weighing slightly more than a woman's was worthless as a testimony of his superior intellectual capacity. Professor Darkchevitch contends from the result of his researches that the sexes as regards brain power are on an equality, and backs up the argument in support of his theory with many convincing illustrations. For instance, Skobeleff's brain weighed less than that of forty individual common soldiers; yet no one would dream for this reason of making the assertion that these men were the superior of Skobeleff in ability. Liebig's brain also was under the average weight.

The opinions on this matter are diverse and various. A large number of persons still hold to the views of Sir William Turner, and with him conscientiously believe that the lesser weight of woman's brain implies in itself the possession of less mental power. On the other hand, many side with Darkchevitch and say that her cumulative and retentive powers are fully equal to those of a man. The question may here be asked: Has woman's intellectual inferiority ever been clearly proved? That it has been is probably the opinion of most persons. From an anatomical and physiological

point of view also she is by many authorities relegated to a position lower than that occupied by man. The supporters of the theory of woman's intellectual inferiority point out, too, with triumph that in scarcely any branch of science, art, or literature has she ever reached quite the front rank. This is all true enough, but it must at least be granted that the cause for a part of her failure should be put down to her comparative lack of opportunity, and the fact should be taken into consideration that up to the present time from the conditions of her life she has been heavily handicapped in the race for fame. May not also the difference in the brains of men and women be looked for not so much in the ponderosity as in the quality? A woman's brain from the nature of things is to a certain extent of another type. The natural rôle of a woman differs widely from that of a man, and she is provided with or has evolved brains suited to her situation. Nevertheless, in these times it often happens that a woman from the stress of circumstances is prevented from fulfilling her natural mission and is compelled to compete with men. She has shown her capability successfully to do so, but in the action must necessarily lose many of her feminine characteristics. The wisest course to take will perhaps be to leave the final settlement of the question in abeyance until the evolution of the new woman has been more fully accomplished.

ULCERATIVE ENDOCARDITIS SUCCESSFULLY TREATED WITH ANTISTREPTOCOCCIC SERUM.

A FURTHER addition is made to the small number of cases of ulcerative endocarditis thus far treated with antistreptococcic serum. Washbourn (*Lancet*, September 18, 1897, p. 707) reports the case of a ward maid, twenty years old, who came under observation complaining of pains in the joints and general malaise. The only significant point in the family history was the death of her father from pulmonary tuberculosis and heart disease. The patient had previously enjoyed good health. Her immediate illness had existed for four days, setting in with pains in the joints, headache, and shivering. She was well nourished and appeared healthy. Especial complaint was made of headache and pains in the knee and thigh. Heart, lungs, and urine were found normal, and there was no swelling or other evidence of disease in any of the joints. The temperature was 100.6° F.; the respiration, 24; the pulse, 104. By the following day the temperature had become normal, and it remained so for three days. At the end of this time it again rose, and for six weeks thereafter the patient suffered from irregular pyrexia, the temperature rising as high as 105° F., and rigors and perspiration were frequent. Heart, lungs, urine, ears, eyes, vagina, and rectum appeared to be perfectly normal. The blood showed slight leucocytosis and slight decrease in hæmoglobin. Some carious teeth were removed, but there was no sign of inflammation in the alveoli. The patient suffered much from constipation, which required the frequent use of aperients. In spite of treatment with quinine and sodium salicylate, she gradually became worse; the rigors were more frequent, the appetite was lost, and pallor and emaciation set in. A distinct diastolic bruit now developed on the left side of the sternum, with its point of maximum intensity in the third intercostal space. It was decided that the pulmonary valve was affected and that the patient was suffering from ulcerative endocarditis. Antistreptococcic serum was injected, the injections being continued daily, with the exception of three days, for nearly nine weeks. At first doses of twenty cubic centimetres were employed, but later these were reduced. Throughout the period of treatment one thousand and thirty cubic centimetres of serum were injected in fifty-nine doses. During the first fortnight of treatment there were only two slight rigors, although the pyrexia persisted. At the end of this time the temperature became normal and remained so for twenty days. The patient now appeared so well that the injections were given on alternate days, but the temperature rising again, the injections were once more given daily. The general condition of the patient began to improve five or six days after the commencement of the injections, and three weeks later she was to all appearances quite well. When she passed from observation she appeared to be in perfect health, although the diastolic bruit in the pulmonary region was still present. At no time did the heart show any sign of enlargement. The only inconvenience noticed from the frequent injection of the serum was slight pain at the site of injection and an urticarial rash which lasted for a few days.

HYSTERICAL PARALYSIS OF THE EXTERNAL RECTI MUSCLES OF THE EYES.

WHILE the symptomatology of hysteria is, comparatively speaking, an open page, the pathology of the disease conversely is practically a sealed book. Although the recognition of well-marked and typical examples of the disease is easy, it is to be feared that many cases are forced into the category of hysteria "by exclusion"—that is, from ignorance as to their exact nature and inability to explain the symptoms present. Hysteria may simulate almost any form of organic disease, and there is scarcely a symptom, subjective or objective, that it may not reproduce; so that at times the diagnosis may remain shrouded in the deepest doubt. A decision can sometimes be reached empirically, one may say, by the skilled observer, from a ready appreciation of the significance of minor and collateral phenomena that attain scarcely to the dignity of symptoms and do not lend themselves readily to verbal description—in a word, from the *tout ensemble* of the case.

A case illustrating some of the points referred to has been reported recently by Dr. Buchanan, in *The Lancet* for July 17, 1897. This occurred in a young woman, thirty years of age, who complained of headache, giddiness, and difficulty of vision. The head-

ache had been present for thirteen days and was soon associated with giddiness, and this in turn was followed by the difficulty in vision. There was nothing significant in the family or personal history of the patient, and there was no evidence suggestive of a neurotic basis for the symptoms. In other respects than those noted she was in perfect health. The headache was almost entirely frontal, not tending to one side more than to the other, generally beginning with pain in the eyes. It was distinctly worse after using the eyes for a time, ceasing at night, and often being present on waking, more especially after the patient had been at work as a dressmaker the night before. The vertigo was general and there was no tendency to fall to one side more than to the other. The patient could stand well with the eyes closed, the feet together, and the hands raised high above the head. She could not "walk a line" well, and an attempt to grasp anything evidently increased the difficulty of the process, so that the visual effort appeared, in part at least, to be the cause of the deficiency.

On examination the external rectus muscle of the right eye was found to be almost completely paralyzed, without convergent strabismus, however. Homonymous diplopia also was present. Ophthalmoscopic examination revealed neither error of refraction nor change in any degree of the fundus of either eye, and there was no evidence of internal ophthalmoplegia. The visual fields were normal for both color and white light. The knee-jerks were normal, and there was no evidence of any organic disorder. The headache and the vertigo appeared to be rather the results than the companion symptoms of the paralysis. A guarded prognosis was given, complete ocular rest was ordered, and the prolonged use of a mixture containing potassium iodide and bromide with nux vomica was recommended. The paralysis rapidly became complete, and convergent strabismus developed. The headache became much less severe and less frequent, but the vertigo continued in much the same degree.

After the lapse of six weeks it was found that the right eye had entirely regained its powers of movement, whereas the external rectus of the left eye was paralyzed and there was marked left convergent strabismus. The left eye also ultimately recovered completely its powers of movement, and in a short while the patient was able to resume her work without inconvenience. She continued in perfect health during the subsequent two years that she remained under observation.

After a careful consideration of all of the possibilities in the case, it came to be looked upon as one of hysterical origin, and it must be admitted that in the present state of knowledge this diagnosis cannot be controverted. In cases of this sort the clinician is pretty much in the position of the man who persisted in spelling socks "sox," and when spoken to upon the subject propounded the somewhat startling and unanswerable query: "If s-o-x don't spell socks, what in thunder does it spell?"

Chicago has entered a claim as a meeting-place for the fourteenth international medical congress in 1903.

THE INFLUENCE OF ENVIRONMENT UPON THE BIOLOGIC PROCESSES OF THE VARIOUS MEMBERS OF THE COLON GROUP OF BACILLI.

As a result of an experimental study carried out in the laboratory of hygiene of the University of Pennsylvania, Dr. Adelaide Ward Peckham (*Journal of Experimental Medicine*, vol. ii., No. 5, September, 1897, p. 549), starting from the assumption that the typical colon bacillus and the typical typhoid bacillus represent the types of the colon group of bacilli that present the greatest divergences in biologic peculiarities, reaches the conclusion that there is a series of closely related forms that may be regarded as intermediate or transitional, and which serve to establish a biologic relationship, either near or remote, between these two typical processes. The typical colon bacillus may be regarded as the type of this group, for the reason that its functional equilibrium, as observed in the intestine, is so permanent a quality that it may readily be perpetuated in what are ordinarily regarded as favorable artificial circumstances, and that with the continuance of such conditions there is no conspicuous tendency on the part of this organism to deviate from what may be considered its norm; whereas, on the other hand, with all the other members of this group that were studied there is not only a lack of uniformity in the adjustment of the functions, but such as exists is readily disturbed under artificial environment—though even with the typical colon bacillus functional modifications are possible under particular conditions.

When the members of the colon group are cultivated under circumstances favorable to the development of both the function of fermentation and that of proteolysis, fermentation invariably takes precedence, and no evidence of proteolysis is manifested until after fermentation has ceased. The cultivation of all the members of the colon group under circumstances that favor the development of one function, viz., that of proteolysis, at the expense of another, viz., that of fermentation, results first in an apparent increase of vigor; but this is of temporary duration, and is quickly followed by decline and death of the cell. The result of this increased activity of the proteolytic functions is the formation of much larger amounts of indol by typical colon cultures than was obtained by any other method. By the method of experimentation through which it was possible to accentuate the proteolytic activity of the typical colon bacillus, as caused by an increase of indol formation, the function of indol formation was induced not only in typical colon bacilli that had been devoid of it, but as well in every specimen of typical typhoid bacilli to which access was had. One of the differential tests between the typhoid and the colon bacillus—namely, that of indol formation upon the part of the latter and the absence of this function from the former—is regarded as of questionable value, for the reason that by particular methods of cultivation indol production was shown to accompany the development of a number of specimens that there was every reason to regard as genuine typhoid bacilli.

As the result of the experiments made, together with

the observations of others, there seems no doubt that the bacillus coli communis at times possesses pathogenic properties, and that by artificial methods of treatment it may often be brought from a condition of benignity to one of virulence.

The spleen of a typhoid patient has always been regarded as the only trustworthy source from which to obtain the typical typhoid bacillus. In addition, it was found that other members of the colon group may also be present in this viscus; in fact, from such spleens could be isolated practically all of the known varieties of this group.

From the experience thus gained the value of the serum test for the differentiation of typhoid and colon bacilli would seem to be questionable. The irregularities noted, however, may be attributed as due more to the method of application than to defects of the principles involved; for by the use of dried blood it is not possible to make the test with constant or accurate or even approximately accurate dilution of the serum.

News of the Week.

New York's Lepers.—The four lepers who have been confined for some time on North Brother Island escaped a few days ago, with the apparent consent of the health authorities, and came to the city. They are now in the temporary charge of the commissioners of charity, awaiting permanent disposition. One was a Chinaman, one a colored man, one a Swede, and one an Irishman. According to the daily papers, the health board is not at all troubled about the escape, as its members do not regard leprosy as sufficiently contagious to be a source of danger to the community.

A Gift to London Hospitals.—The firm of Barnato Brothers has distributed a sum equivalent to over $80,000 among the London hospitals. It is announced that the money is given in fulfilment of the known intentions of Barney Barnato, the South African millionaire who committed suicide last June by jumping overboard from the steamer on which he was travelling from Cape Town to England.

The Yellow Fever.—Up to October 19th the total number of cases of yellow fever in the South has been 1,649. The proportion of deaths has been rather higher during the past week, bringing the mortality rate up a little above ten per cent. The disease has invaded Baton Rouge and some other places where what was supposed to be a most effective quarantine has been maintained from the first day the disease prevailing at Ocean Springs was pronounced to be yellow fever. The authorities, who cannot believe that their shotgun quarantines could possibly be evaded, comfort themselves with the assertion that the doctors know nothing of the fever, either of its nature or of the mode of its spread. The record for Tuesday of this week was: New Orleans—new cases, 37; total cases, 865; deaths to-day, 7; total deaths, 100. Mobile—new cases, 6; total cases, 170; deaths to-day, 1; total deaths, 22. Edwards—new cases, 4; total cases, 463; deaths to-day, 3; total deaths, 30. Patterson—new cases, 3; deaths to-day, 1. Baton Rouge—new cases, 1. Pascagoula—new cases, 2; total cases, 15. Scranton—new cases, 13; total, 194. Cayuga—new cases, 3; total cases, 18; deaths to-day, 1. Flomaton, Ala.—new cases, 16; total, 20. It is said that a suspicious fever has been prevailing for five or six weeks in Montgomery, Ala., but the health board has steadily maintained that it was not yellow fever. Early this week, however, the board admitted that there were two genuine cases in the city, and now the impression prevails that all the other cases were also of the same disease.

The Plague is reported from Madras, so that now it prevails on both coasts of the Indian peninsula.

The Leprosy Congress.—The closing session of the International Leprosy Congress was held in Berlin on October 16th. The discussions covered nearly every point relating to the etiology, pathology, bacteriology, symptomatology, and treatment of leprosy. To judge from the cable reports of the congress, there has been little brought forward that added to our knowledge of the disease. Babes, of Bucharest, in a paper on the bacteriology of leprosy, stated that Hansen's bacilli were found in great numbers in the mucous excretion, which was thus one of the chief means for conveying infection. The members of the congress were unanimous in their belief that Hansen's bacillus was the specific pathogenic micro-organism, and that it finds in man alone of all animals a suitable soil for its growth. The treatment was declared to be as yet palliative only and not curative; orrhotherapy was discussed at length, and the conclusion arrived at was that it has not yet been found of service in leprosy. The question of isolation in the prevention of the disease was also thoroughly discussed. Hansen, of Bergen, Norway, argued at length in favor of isolation, and said that his experience justified the prediction that, owing to the rigid isolation so long practised in Norway, the disease would disappear entirely there by the beginning of the twentieth century. If the same measures were followed universally, leprosy would be eradicated quickly. He insisted upon the observance of the most scrupulous cleanliness. This, he added, was more strictly observed in the United States than in Europe, the result being, despite immigration, that the disease had not spread there. Besnier, of Paris, held that isolation was not necessary if proper precautions were taken to guard against contagion. At the closing session the opinion was adopted by the congress that leprosy, while contagious, is not hereditary, and it was held that isolation is desirable and under certain circumstances is to be enforced by the authorities. The congress was closed by Virchow, who urged the co-operation of government and science. He hoped this congress would be the first of a series of international debates concerning various diseases of as yet obscure nature.

The Strafford District (N. H.) Medical Society.—The nineteenth annual meeting of this society was held in Dover on October 13th, under the presidency

of Dr. A. Noel Smith. The title of the presidential address was "The Economic Worth of the Physician."

A Decision against the Health Board.—The appellate division of the supreme court has handed down a decision that the health department of this city exceeded its authority and acted without due warrant of law in condemning and destroying four rear tenements in Mott Street some time ago. It was not denied that the tenements were unfit for human habitation, but it was contended that the buildings might have served some other purpose and should not have been razed. The appellate court decision will be appealed to the court of appeals.

Typhus Fever in Mexico City.—The unsanitary condition of the city and the protracted rainy season are causing much sickness in Mexico. During the past three months over six hundred cases of typhus fever have been reported, and there have been about one hundred and fifty deaths from that disease.

Ambulance Ships.—It is stated in the annual report of the surgeon-general of the navy, recently made public, that new methods of succor for the wounded must be devised to meet new conditions, and, with this object in view, plans for an ambulance ship have been prepared under the supervision of Medical Director W. K. Van Reypen. A recommendation for authority to establish a hospital corps for the navy is also contained in the report.

Small-pox in Atlanta.—Several cases of small-pox have developed in Atlanta within the past two weeks, and as a result the board of health has decided to begin compulsory vaccination throughout the city. It is not thought here that the disease will assume an epidemic form.

Health Statistics of New Brunswick.—In the annual report of the board of health of the city of New Brunswick to the New Jersey State board of health, the population of New Brunswick at the last census is given as 19,010; the number of births for the year ending June 30th were 408; deaths, 499; drowning cases, 13; deaths from railroad accidents, 11; and suicides, 3.

A Memorial Operating-Room in the Jamaica Hospital.—Miss Mary R. King, of Great Neck, Long Island, has offered to furnish and equip the operating-room of the Jamaica Hospital, now building on New York Avenue, in memory of her aunt, the late Miss Cornelia King, of Jamaica, who had taken great interest in this work.

Hydrophobia in Prussia.—According to official statistics, 107 persons died of hydrophobia in Prussia in the years from 1877 to 1894, but there was not a single death from that cause in 1895, although 368 cases of mad dogs were reported and 906 suspected animals, in addition, were killed by the police.

Dr. Lewis Balch, ranking major of the national guard, has been retired from the tenth battalion, of Albany, of which he was the surgeon.

Lay Treatment of Enuresis.—According to newspaper accounts two little girls, inmates of an orphan home at Madalin, were shut up in a pigpen and kept there for forty-eight hours on bread and water, as a punishment for wetting the bed. If this report is true, it would seem in order for the trustees to engage a new matron or instil a little common sense and humanity into the head and heart of the present incumbent.

Killed for Evading Quarantine.—A negro was lynched by a mob at a small settlement about fifteen miles from New Orleans, because he had been in the city and had evaded the shotgun quarantine established everywhere against the yellow fever.

The Chicago Medical Society has recently moved into the Stewart Building, where sufficient space has been rented to provide for a meeting-hall, committee rooms, a reading-room and library, cloak rooms, etc. It is hoped to make this the centre for all the medical societies of the city. The society has been in existence forty-five years, and has a membership of nearly eight hundred.

Illegal Practice of Dentistry.—A man who was recently convicted of practising dentistry without previous registration, as required by the law of this State, was fined $150 in special sessions. The three justices agreed in regarding the accused's action as a clear violation of the law, and said that they believed the dental law to be for the general good of the public, and expressed their pleasure in the opportunity afforded them of upholding the law. The man's employer was sharply rebuked for consenting to his violation of the dental act, and, perhaps as a mark of contrition or in reparation of his wrong, he paid the prisoner's fine.

The Syracuse College of Medicine.—Four names have been added to the faculty of this college, the opening session of which for the new year was held on October 5th. Dr. Charles W. Hargitt has been appointed lecturer on embryology, and will be assisted by Dr. F. P. Knowlton. Drs. W. L. Wallace and George B. Broad have been appointed instructors in anatomy.

Premature Burial.—The United States consul at Turin has sent a communication to the state department, stating that leading physicians in Italy are now engaged in preparing reports and exhibits relating to the phenomena of trance, and that papers on the means of distinguishing real from apparent death are expected from writers in all parts of Europe. Prizes will be awarded for papers offering the best solution of this problem. The consul says that not only the medical profession but many lay persons are interested, and that the medical section of the national exposition to be held at Turin in 1898 is to be largely devoted to the subject.

A Dental College "in Petto."—It is reported that Dr. Thomas W. Evans, the well-known dentist in Paris, intends to leave the bulk of his large fortune, estimated by some at upward of $30,000,000, to charitable and educational institutions in this country. It is said that he purposes to establish an elaborately equipped dental college in Philadelphia, in which the tuition is

to be practically free to deserving students. He has recently been in this country, and has consulted with many members of the dental profession in the leading cities concerning his plans for a new school.

Racial Immunity to Tuberculosis.—Some interesting observations, we learn from the *Medical Press*, have recently been made public by two Parisian physicians in respect of a group of people inhabiting St. Ouen, a district of suburban Paris, who appear to enjoy complete immunity from the scourge of phthisis. These observations bear on ninety-eight families, comprising five hundred and eleven members, of whom none has succumbed to consumption since 1883. As a matter of fact, this immunity seems of old standing, for researches extending as far back as 1870 revealed no record of death due to this cause. Tuberculosis is responsible for something like three deaths per thousand inhabitants per annum, and it is specially fatal among nurses and hospital attendants; indeed, during the last ten years phthisis claimed two hundred and seventeen victims out of five hundred and ninety-nine deaths among hospital attendants in Paris alone.

Decline of the Plague in China.—The United States consul at Amoy has reported to the state department that the bubonic plague, which has raged in that section of China for three months, is now regarded as having run its course.

A Trial of Typhoid Vaccine is being made on a large scale at Maidstone, England, where one of the severest epidemics of the disease ever known is now prevailing, fifteen hundred people out of a population of thirty-two thousand having already been stricken. The experiments are being conducted under the direction of the pathological laboratory of the State Army School at Netley, by Professor Wright and Surgeon-Major Temple. It is said that these have so improved the method that they are able to obtain Widal's reaction from the blood of the vaccinated, which is taken as a proof that the individual is protected by the injection. Enough vaccine has been sent to Maidstone to inoculate the whole population if necessary.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending October 16, 1897. October 9th.—Assistant Surgeon A. Farenholt detached from the *Vermont* and ordered to New York navy yard. October 11th.—Surgeon C. G. Herndon ordered on temporary duty at the naval museum of hygiene. October 12th.—Assistant Surgeon W. B. Grove detached from naval laboratory, New York, and ordered to Mare Island Hospital. October 13th.—Passed Assistant Surgeon C. P. Bagg detached from the *Marion* and ordered to the *Adams;* Assistant Surgeon M. K. Johnson detached from the *New York* and ordered to duty with the *Vicksburg;* Assistant Surgeon R. Spear detached from the naval laboratory, New York, and ordered to the *New York*. October 14th.—Surgeon C. Biddle detached from marine rendezvous, San Francisco, ordered to Washington in charge of patient, then to report at the navy department.

Malignant Malaria.—It is reported from St. Petersburg that malaria, which has been prevalent at Tashkend, Asiatic Russia, for four years, has now become virulent, and the deaths from that cause are estimated to number several thousand. The Russian garrison at Merv, where influenza as well as malaria prevails, has been transferred to Krasnovodsk, on the Caspian Sea, to prevent its being annihilated by disease.

The Idaho State Medical Society held its fifth annual meeting at Boise City on Tuesday and Wednesday, September 15 and 16, 1897. The newly elected officers are: Dr. C. A. Hoover, Montpelier, *President;* Dr. R. C. Coffey, Moscow, *Vice-President;* and Dr. Ed. E. Maxey, Caldwell, *Secretary* and *Treasurer*. The next meeting will be held at Moscow, Idaho, the first Tuesday in September, 1898.

The New Jamaica Hospital.—The laying of the cornerstone of the new building for the Jamaica, Long Island, Hospital, which is to be located on New York Avenue, that village, took place on Saturday afternoon last. The cornerstone was laid by Miss Gale, the president of the board of trustees of the Hospital Association. The new building will probably be completed by January.

Obituary Notes.—Dr. Theodore Todd Munro, of Union, S. C., died by suicide on October 10th, at Atlanta, Ga., whither he had been taken for treatment of the opium habit.—Dr. Joseph C. Wheaton died at Millville, N. J., on October 13th, after a brief illness. He enjoyed a large practice and was active among the poor and needy.—Dr. Newton E. Bates, surgeon-general of the United States navy, died in Washington on October 18th, at the age of sixty years. He was appointed surgeon-general to succeed Surgeon-General Tryon on October 1st, and was obliged on account of the illness which finally resulted in his death to take the oath of office in bed. His illness at that time was not regarded as serious, but developed alarming symptoms a few days ago. Dr. Bates was appointed assistant surgeon in the navy from New York State in June, 1861. He became surgeon in 1865, medical inspector in 1881, and for nine years prior to his appointment as surgeon-general was a medical director with the relative rank of captain. He was the President's family physician.—Dr. James P. Daly, of this city, the Tammany candidate for coroner in the Borough of the Bronx, died suddenly on October 15th. He was a graduate of Bellevue Hospital Medical College in the class of 1886.—Dr. Girard Robinson Ricketts died at his home in Proctorville, Ohio, September 20, 1897. He was born in Virginia in 1828, and was graduated from the Western Reserve Medical College of Cleveland, Ohio, in 1855. His three sons, Drs. Edwin S., B. Merrill, and Joseph V. Ricketts, are all practising physicians in Cincinnati.—Dr. William H. Ford, president of the board of health of Philadelphia, died suddenly, October 19th, at his summer home in Belmar, N. J., aged fifty-eight years. He was well known as a writer on hygiene and sanitation. He had been a member of the board of health for twenty-seven years.

Society Reports.

NEW YORK STATE MEDICAL ASSOCIATION.

Fourteenth Annual Meeting, Held in New York, October 12, 13, and 14, 1897.

CHARLES PHELPS, M.D., PRESIDENT.

Second Day—Wednesday, October 13th.

(Continued from page 571.

Hysteria and a Study of the Symptoms Observed during the Inter-Paroxysmal Period.—DR. WILLIAM D. GRANGER, of Westchester County, read this paper. He said that hysteria must be considered as essentially a psychosis, the predominant symptoms of which were attributable to the cortex of the brain. The symptoms of the interparoxysmal period were classified thus: (1) Disturbances of sensation, such as anæsthesia, paræsthesia, and hyperæsthesia; (2) disturbances of motion, such as paralysis, contractures, and tremor; (3) vasomotor, visceral, and nutritional disturbances; (4) mental symptoms; and (5) unclassified symptoms. Disturbances of sensation, particularly analgesia, were rarely absent in the graver forms of hysteria. The most frequent form of disturbance was a hemi-anæsthesia affecting exactly one-half of the body. Every one, the speaker said, was familiar with the "hysterical spine." Pains in the joints were generally confined to the larger joints. All sorts of pains were experienced in the head and face. The classical "hysterical clavus" of Sydenham was an intense pain of circumscribed area, usually at the vertex. The pains in the abdomen were quite scattered, yet in general they were more or less connected with the ramifications of the ovarian plexus of nerves. The ovarian zone was, of course, the one most commonly affected. In hysterical paralysis the patient usually dragged the limb, instead of swinging it as did the true paralytic. The electrical reactions would also be found to be normal and the skin would be unchanged. In connection with the well-known hysterical spasm of the throat, one often observed that the patient would refuse food. It was here that we met with the cases of deception, commonly called "fasting girls," but aside from the cases of palpable fraud there were well-authenticated instances in which such hysterical patients had been able to live for a long time upon a comparatively small amount of nourishment. The symptoms connected with the chest were insignificant when compared with those referable to the abdomen. Vomiting of blood was occasionally one of the stigmata of hysteria. Hysterical œdema was a very rare condition, due to vasomotor disturbance. The reports of extremely high temperature could be put down as fallacious, although a pseudo-hysterical fever had been noted, in which there was no actual rise of the body temperature. A rise of only two or three degrees was sometimes observed in hysterical cases, and was not amenable to treatment by the usual antipyretic drugs.

DR. HANAN, of Rensselaer County, detailed at length his experience with a case of hysteria, which some surgeons, notably a certain eminent one from New York City, had insisted was a case of organic pelvic disease demanding immediate operation. He had been astounded and disgusted to see this patient placed on the operating-table, and then at the last moment the operator refuse to operate. Notwithstanding various diagnoses and treatments, this patient was still in much the same condition as at first.

DR. VAN DE WARKER said that to his mind the most remarkable thing about this case was that the woman had, during all this trying period, succeeded in retaining her tubes and ovaries.

Massage as an Occupation for the Blind.—DR. ARTHUR Y. BENNETT, of Erie County, in a paper with this title, made the statement that there were over four thousand blind persons in New York State, and that so far as he had been able to ascertain from circular letters of inquiry probably not more than from six to ten per cent. were able to support themselves. Among blind women the percentage was very much smaller. He was of the opinion that the blind should be able to make massage their own peculiar profession. One of their special qualifications for such work was their well-known extraordinary delicacy of touch. Moreover, the blindness itself was an actual advantage, because it enabled the massage operators to carry on the necessary manipulations without being able to detect various bodily deformities and blemishes, about which most people were very sensitive. It was bad enough to expose the body to their physician, but it was many times worse to do this in the presence of a strange massage operator.

DR. THORNTON, of Buffalo, expressed the belief that this valuable suggestion should receive the hearty co-operation and support of the medical profession.

Differential Diagnosis of Pelvic Cellulitis and Peritonitis.—DR. ELY VAN DE WARKER, of Onondaga County, read the paper. He said that it was his aim to show that pelvic peritonitis and cellulitis were distinct entities, and that each disease had clinically discernible traits by which each could be differentiated. For example, the masses of peritonitis and cellulitis occupied positions so different that this alone should prevent the confusion of the two conditions. He had found one important symptom in cases of cellulitis—*i.e.*, retraction of the thigh. There was a good anatomical explanation for the fact that this symptom was so characteristic of cellulitis. It was never seen in uncomplicated pelvic peritonitis. Phlebitis and enlargement of the limb were also indicative of the condition. Another very highly characteristic and unfailing sign of pelvic cellulitis was the existence of a well-defined mass of cellular infiltration into the lateral wall of the vagina and continuous with the lateral vaginal vault. The remainder of the paper was devoted to an elaboration of these views.

Wednesday, October 13th—Night Session.

The New Epoch in the Study of Pathology, by DR. IRA VAN GIESON, was the first paper. Dr. Van Gieson said it sounded a little sententious to speak of the "new epoch," but we could often speak of the old with new terms and better ideas. There were four cardinal factors which gave new views of the pathology of the nervous system. First, that the nerve fibre was not separate and distinct in character from the cells, but was the extension, as it were, of the cell. The two were anatomically and physiologically a unit. The tendency to think that the white matter and gray matter of the brain differed led to confusion, and it was a great gain to understand that the fibre was the outgrowth of the cell, whether that be motor or sensory. Second, that the linking of physiological chemistry and pathological anatomy aided in the understanding of the phenomena hitherto obscure. Third, the great advancement in cytology, by which it was known that the cells were in themselves a microcosm. This advancement in the knowledge of nerve-cell structure had been made by the biologists in the last few years. It was to be expected that the study of pathology would now be devoted more to the changes in the cells themselves than to the mass, for the cells had structural relations within themselves even as had the different organs of the body. Fourth, the comparison of the pathology of the nerve cells with that of other parts of the body. Singularly the nervous system had been studied as a

separate part of the body. The fact that the pathology of the nervous system had not been correlated with that of other parts of the body, had retarded its study. What will happen in the cellular structure of the kidneys and the liver when toxins come in contact with them may be assumed as happening also when toxins come in contact with cellular tissues of the nervous system. We might flatter ourselves that we knew much of the physical basis that underlay disease of the nervous system, but to say that locomotor ataxia was caused by sclerosis of the posterior columns of the spinal cord was to give not the cause, but the result of some changes that had taken place in the nerves. It did not explain the beginning of the disease. We were acquainted with what could be seen with the naked eye or the lower power of the microscope, but as to cell structure nothing was known, for it was not visible when sections were hardened in Müller's fluid. Dr. Van Gieson emphasized the point that the method of examining nerve cells by the use of Müller's fluid destroyed all opportunity of studying the internal structure of the cell. Pathological conditions seemed complicated, but he thought they could all be reduced to three forms—degeneration, inflammation, and necrosis. Instead of each disease having a different pathological lesion, he thought all could be traced to one of these three acting with varying intensity. These processes were found in the nervous system, and while the results might be modified, yet they were homologous to the same processes in the kidney or liver. Disease might be defined as the chemical reaction between the toxin forces on the one hand and the body forces on the other. If X represented the toxic forces and Y the body forces, the disease was represented by the ratio between these. The disease varied as the toxic forces varied or the body force varied; hence it might be represented as $dX : dY$, in which d represented differentially the varying force. The toxic force was influenced by amount of poison, how long acting, etc.; the body force by age, sex, heredity, etc.

Dr. Van Gieson discussed at some length the resisting forces of the body, and showed how they counteracted the toxic forces and how disease varied in relative proportion to the variation in these forces. By toxin he did not mean the result of bacterial life, but used the term in the broader sense of applying to all deleterious material which might impair the body. The results of the varying of body and toxic forces might be compared to the changing of the relative position of a few pieces of glass, producing many varying conditions. He then compared the structure of the brain to that of the kidney. The kidney was composed of parenchyma and stroma. The parenchyma was composed of cells which could be compared to the nerve cells; the stroma to the neuroglia. When there was a disturbance in the kidney, a lack of blood supply, too much blood, presence of any toxins, we saw the result in what we called cloudy degeneration. The cells were affected, became cloudy, broke down, and were destroyed, the result varying with the amount of toxin and the length of time it acted. The brain did not escape this similar result and hence followed delirium of fevers, etc.; cloudy swelling, it might be said, of the brain cells. This swelling is not seen on examination, because of the use of Müller's fluid. By the use of the blackboard Dr. Van Gieson showed how the fibrillæ of the nerve cells crossed, and how where they crossed there were minute nodes called microsomes. These were acted upon by the toxin, began to break down, and if the process continued the result would be the cloudy swelling of the cell and finally its destruction. This cloudy swelling explained delirium, which, when occurring by itself, was called insanity.

As we conclude in the case of the kidney what the prognosis is to be, so with the brain. The kidney recovered in full if not affected too long and too severely; so the brain. The one was the homologue of the other. The prognosis was affected by the body force. Thus insolation occurring in alcoholics was of doubtful prognosis on account of the body force and the condition of the cellular structure. The following diagram illustrated his idea of recovery:

There was a point beyond which there was no recovery—where the cell structure was affected; where the cells became broken down (cytoclasis, cell destruction)—but up to this point there was a possibility of recovery when the poison was removed (cytolysis, cell resolution). When the poison ceased to act, the cells began to restore their normal condition (cytothesis).

There was more hope of restitution in cases of acute infection than in chronic. A small amount of poison acting for a long time would make repair less hopeful than the action of the acute attack. Thus syphilis produced in its insidious way more damage to the cell than the acute fever, and made cytothesis less likely to take place. On the ground of cytoclasis it was easy to understand the existence of locomotor ataxia. The nerve cell underwent degeneration by the action of insidious poison. This resulted in the death of the fibre, and finally by inflammatory restitution its place was taken by tissue and it became a permanent lesion. Seeming improvement could be explained by understanding that some of the cells had not gone on to cytoclasis, and when the poison abated for a short time they began cytothesis and thus the symptoms might improve for a week or so.

The Conservative Surgical Treatment of Fibro-Myoma.—Dr. E. E. Montgomery read a paper upon this subject. He said that hysterectomy, vaginal or abdominal, could be considered conservative when performed to save life. He would not justify the retention of the uterus if there was disease of the tubes and ovaries, but in many cases these could be saved. Growths could be attacked per vaginam or by way of the abdomen—per vaginam by dilatation of the cervix, incision of the cervix, removal by torsion or by enucleation from the capsule. Curetting of the uterus might be employed to stop bleeding. A tumor that was pedunculated could be removed by three or four twists, but this could not be done if the tumor was encapsulated and partially inclosed in the walls of the uterus. Then there was danger from hemorrhage. Some had obtained favorable results by cutting off the blood supply from the tumor. This, as done by Martin, included ligation of the whole base of the broad ligament. It could be done without entering the peritoneal cavity, but there was some danger of ligating the ureter. This arrest of blood supply caused diminution of the tumor. He wished to assert that by using these various methods it was possible to remove tumors without sacrificing the body of the uterus. If the growth was in a woman near the climacteric, the uterus might well be removed, but if in a young woman the organ ought to be saved if possible. The cervix could be dilated with the finger or with tents, using one large one or several small ones, allowing them to remain from twelve to twenty-four hours. Careful cleansing was necessary. The vagina and cervix could be cleansed with formalin solution, the vagina being afterward packed with iodoform gauze. If the growth was near the fundus the cervix might be incised, a lateral incision extending well up but not entering the peritoneum being preferable. If pedunculated, the tumor might be removed by torsion; if encapsulated, by splitting the capsule, enucleating with a blunt dissector in preference to the

finger; and if the tumor was large, some morcellation might be necessary. After removal the incisions in the cervix were brought together by sutures, and the whole was thoroughly cleaned and packed with gauze. For the ready accomplishment of removal of a tumor through the vagina the uterus must be movable and the tumor not larger than the fist. If the case was not suited to this method, the tumor must be removed through the abdominal wall. Mural or intramural tumors were not to be thus considered.

Some Remarks on Ovarian Surgery.—Dr. A. Palmer Dudley read the paper on this subject. He read this paper in answer to some criticism on his work and to put on record some work he had done in contradistinction to radical operations. He thought the pendulum had swung too far, and radical operations were often done when conservative work would give better results. The operation of hysterectomy had become almost perfect. The French were so expert that child-bearing was becoming a very grave question, the government offering pensions to those who raised large families. He thought the government might well pension its surgeons and thus save the child-bearing power of the women. The question was: To what extent can conservative operations be performed with safety to the patient? A number of years ago he had seen the removal of a healthy ovary followed by the recovery of the patient, and had determined to see if the ovaries when only partly involved could not be operated upon and the unaffected portion saved. He had operated on a woman, removed a portion of one ovary, brought the edges together, and sewed them with fine silk. The woman became pregnant in a few months afterward. He had records of sixty-eight patients and all had done well. Eight of these had since borne children. In all these cases he had not seen a recurrence of any inflammation that could be detected by manual touch. He had never treated the ovaries with the cautery; he punctured the cysts, sometimes scratching the sac until it filled with blood. He thought the cautery destroyed too much healthy tissue. It was best to save all the tissue possible, but when necessary the operation had included nearly the entire ovary. In operations on the ovary he never used animal sutures, but fine silk. The tubes could be partially removed with good results. Even pus tubes could be saved by removing the portion in which there was pus, splitting the end remaining, sewing the mucous membrane to the peritoneal covering, thus leaving a cup-like end which performed the function of the fimbriated extremity. To this the ovary was attached by a single suture of silk. Some reasons why radical operations should not be performed when avoidable were, retaining the integrity of the home, avoiding nervous symptoms sometimes worse than the original disease, and saving the women from barrenness.

Dr. Fred Holme Wiggin presented a large tumor removed from a patient at the City Hospital. The woman was forty-two years old, was never pregnant, and had suffered from tumor over a year. She was weak, but suffered such pain that she and her husband asked for the operation. On account of the patient's condition the tumor was rapidly removed and the uterus sewed up; the patient recovered.

Dr. Dudley mentioned a case of a young girl suffering from a large tumor. He opened the abdomen and the uterus, removed the tumor, and sewed the uterus up, leaving a gauze drain from the abdominal wall through the vagina. Afterward the gauze was drawn up a little, cut off, and the remainder withdrawn through the vagina. The patient recovered.

Dr. E. D. Ferguson said he considered the question of myomectomy important. Fibromas were seldom single but were multiple—many small ones, seeds as it were. It was a question if leaving the uterus in this condition was conservative surgery for the patient. In subjects nearing the climacteric he thought it best to perform hysterectomy, but of course in the case of a young woman it was necessary to save the uterus if possible. Still it was a question if myomectomy would not become a fad, to the detriment of the patient.

Dr. J. E. Janvrin said he wished to congratulate Dr. Dudley on his conservative work. Most of the men who did much operating took this same ground of conservative surgery. He thought this was the safe ground. Dr. Montgomery's paper had, in a new way, presented facts relating to an old field and he congratulated the doctor on his success. The removal of tumors from the uterus had been done in a somewhat crude way for years. All tumors of the uterus, when the tubes and ovaries were in a healthy condition and the woman was young, should be dealt with in this way.

Dr. Wiggin said that in women under forty years of age he always left the uterus unless it was so diseased as to demand removal.

Dr. Montgomery said he would not suggest operation to save the uterus if the climacteric was near at hand. He was interested in Dr. Dudley's paper, and he had not before heard the suggestion as to leaving the end of the tube with a cup-like receptacle for the reception of the ovum. He had known removal of a diseased ovary to bring about the return of menstruation in a woman who had been irregular but who was not at the time of operation pregnant.

Third Day—Thursday, October 14th.

Officers Elected.—*President*, Dr. Douglas Ayres, of Fort Plain; *Vice-Presidents*, Second District, Dr. C. E. Fritts, of Hudson; Third District, Dr. H. W. Carpenter, of Oneida; Fourth District, Dr. C. C. Frederick, of Buffalo; Fifth District, Dr. N. W. Leighton, of Brooklyn; *Members of the Council*, First District, Dr. W. H. Robb, of Amsterdam; Second District, Dr. E. M. Lyon, of Plattsburg; Third District, Dr. W. L. Ayer, of Owego; Fourth District, Dr. J. G. Truax, of New York.

Subscription to the Rush Monument Fund.—Dr. Thomas H. Manley, of New York, moved that the treasurer of the association be authorized, in conformity with the pledge of the representative at the last meeting of the American Medical Association, in Philadelphia, to pay to the Rush monument fund the sum of $2,000, in the name of the New York State Medical Association. After some discussion and explanation the motion was carried without a dissenting vote.

General Considerations concerning Auto-Intoxication.—Dr. H. A. Hanbold, of New York, read a paper with this title. He said that the theory of auto-intoxication had found but little acceptance in the profession up to recent times. The explanation was to be found in the statement of Albu, of Berlin, that the general practitioner knew but little of physiological chemistry, which was necessary to an understanding of the subject. But recent investigations into the poisons developed spontaneously in the body in connection with general metabolism had given the subject considerable importance. The development of the science of bacteriology had led to the belief that the infection itself constituted only a portion of the etiological factors concerned in disease. In the majority of instances intoxication was secondary to infection, the intoxicants being the products of infection; but we were also justified in believing that primary intoxication was a frequent cause of disease, and that poisons might develop within the body. Examples were to be found in the saliva of poisonous snakes, animals affected with rabies, and in tetanus. The facts in our possession substantiating the theory of auto-intoxica-

tion were still few in number, but they constituted a firm basis for experimentation. Auto-intoxication consisted in a poisoning of the organism with the products of metabolism, existing normally but present in excessive quantity, or with abnormal toxic substances. The latter class was again divided into those undergoing further modification and those existing in the body only in minute quantity. In the gastro-intestinal canal the nutritive constituents underwent certain changes which rendered them capable of assimilation. The end products of disassimilation were for the most part simple compounds, such as water, the inorganic salts, urea, and the urinary salts, but the intermediate products of metabolism were far more complex in nature and difficult of investigation. Under pathological conditions they accumulated in the body and acted as auto-intoxicants. Gautier called these intermediate substances "leucomains," and believed them to be the cause of many pathological conditions. Disturbances of metabolism resulting in auto-intoxication were not limited to the albuminoids, but were due to the accumulation of intermediary products of the fats and carbohydrates. Under normal conditions it was claimed there always existed small quantities of certain toxic substances formed in connection with the processes of metabolism, but under unnatural conditions these poisonous substances might accumulate in the system in such quantity as to give rise to auto-intoxication. The toxicants circulating in the blood acted as irritants to the organs. If this irritation were transitory, the intoxication would be acute; if the disturbance were frequently repeated, it would result in a chronic auto-intoxication. It was naturally a task of much difficulty to prepare a clearly defined classification of these newly born poisons. Under the head of auto-intoxications von Jaksch, Kobert, Schwalbe, and Bouchard included all the diseases the result of a *contagium vivum—i.e.*, the infectious diseases; but, although our present knowledge justified the belief that most of the symptoms of the infectious diseases were produced by an intoxication with the modified products of metabolism, it should be remembered that these modifications were caused by microorganisms. This was but another way of saying that these intoxicants were the result of matters introduced from without—that they were exogenous poisons.

The author then took up briefly: (1) The origin or source of auto-intoxication; (2) the conditions governing its development; and (3) its manifestations or symptomatology. Under the first head were mentioned auto-intoxications arising from: (1) The skin—as the phenomena following severe burns; (2) the lungs—as carbonic-acid poisoning; (3) the kidneys—as uræmia and eclampsia; (4) the suprarenal capsules—as Addison's disease; (5) the gastro-intestinal canal (including not only the various constitutional disturbances consequent upon diseases of the stomach and intestines, but acute yellow atrophy of the liver, icterus gravis, cholæmia, and diabetes mellitus); and (6) the thyroid gland—as myxœdema, cachexia strumipriva, and possibly Basedow's disease.

As to the conditions governing the development of auto-intoxication, it should be said that it occurs only when secreting or excreting organs are functionating improperly. Individual predisposition was an important factor in the causation of auto-intoxication, and was almost certainly a neuropathic one. It was evident that if this individual element was not an important etiological factor, auto-intoxications would be much more frequent.

As might be expected, the symptomatology was extremely complex; for, although a single organ might be at fault, the resulting disturbances were usually very general in character. Aside from the very large number of auto-intoxications referable to an organ or definite part of the body, there were a number—such as chlorosis, pernicious anæmia, leukæmia, and the various cachexias—that found expression only in a general disturbance of the metabolism.

Asepsis and Antisepsis in Obstetrics, from the Standpoint of Present Scientific Knowledge.—Dr. George Tucker Harrison, of New York, read this paper. He said that in the whole history of medicine he knew of no more pathetic story than that of the illustrious Semmelweiss, whose memory should be cherished and revered by all who took an interest in obstetrics and in the welfare of puerperal women. It was left for this great man to make the first grand and successful effort to reduce the appalling mortality from puerperal fever. The first clew that he had received was at an autopsy on a medical man who had died as a result of infection from a dissection wound. He was at once impressed with the fact that the changes in the blood and lymph channels bore a striking resemblance to those observed in post mortems on women dying of puerperal fever, and this picture pursued him night and day until the truth dawned upon him. He found that, in the division of the hospital in which the mortality among puerperal women was so terrible, it was the custom for the students to come directly from the post-mortem room to the obstetric wards. The order accordingly went forth that all those in attendance on these lying-in women should invariably wash the hands with chlorine water before making any examinations. The good effect of this innovation was immediate and remarkable, the mortality being greatly diminished; indeed, at the present time the key to avoidance of this dreadful scourge was found in careful cleansing and antisepsis of the hands, and in making as few examinations as possible. The author of the paper said that he wished to enter a most emphatic protest against douching and scrubbing the vagina before labor—a practice advocated by some obstetricians. In his opinion such treatment was not only unnecessary but pernicious, if for no other reason than that it removed the normal protective vaginal mucus and caused abrasions of the vaginal mucous membrane. The dry, harsh feeling of the vagina after a bichloride douche was an indication that the use of antiseptics might even serve to retard and obstruct labor. Only the external genitals should be cleansed; cleansing of the internal genital organs should be entirely omitted. We should distinguish clinically between putrid or saprophytic endometritis and the septic variety. In the former a granulation area was soon formed and afforded a barrier which the bacteria could not penetrate. If this barrier was broken down by the curette, general infection might ensue. He believed that the exaggerated use of local therapeutics was responsible for many deaths. We had no means of ascertaining with certainty when the process might be considered to be localized. He had long since ceased to use disinfectant irrigations before and after operative procedures.

Dr. Eden V. Delphy asked if Dr. Harrison objected to all operative measures in puerperal sepsis.

Dr. Harrison replied that his doctrine was that local therapeutic measures were justifiable only when it might be safely assumed that the septic process was localized in the uterus. If it was not thus localized, there could be no sense in such treatment.

Dr. Delphy cited the case of a puerperal woman, who had had a rapid pulse and a temperature of 105° F. at the time he had been called. On curetting the uterus, foul pus had escaped. The patient was in collapse for two hours after the operation, but eventually recovered. He had operated upon other severe cases with good results. It was true that there had been too much meddling with the vagina, both before and during labor. It ought to suffice for the physician to get

himself and the outside of his patient clean. Of course it was possible that auto-infection might occur from an old pyosalpinx. He did not know how the physician was to tell whether or not the septic process had stopped at the uterine wall.

Dr. Harrison, in closing, remarked that he thought Dr. Delphy had been very fortunate in the case he had cited, if there had been pus in the uterus.

Gyves and Trigs (Bonds and Obstacles).—Dr. H. D. Didama, of Syracuse, read a paper with this quaint title. He took up first the question of venesection, and showed that previous to 1847 the medical profession had been held in the "gyves" of a so-called experience, and that the leaders and authorities had become so habituated to the bonds that they felt no galling. Only forty years ago it was still the opinion of such masters as the great Thomas Watson that the value of phlebotomy in pneumonia was well attested by experience. Nevertheless the treatment was not such a great success after all, for the statistics of one of the English hospitals were published about that time, and they showed that out of six hundred and forty-eight patients treated by venesection, two hundred and twenty-two—or more than one in three—died. In 1865 John Hughes Bennett had published in detail the cases treated by him for fifteen years in the University Hospital by mild supporting treatment without venesection. The mortality in this series was one in forty, and in the simple uncomplicated cases scarcely one in one thousand. In 1860 our own Flint had given utterance to the opinion that experience and pathological knowledge showed that general blood-letting did not exert a direct controlling effect on an inflammatory disease.

The remainder of the paper was devoted to a consideration of the place alcohol should hold in rational medicine. The author quoted from various sources to show the inconsistencies and absurdities of teaching of which medical observers were guilty in connection with the use of alcoholics in the treatment of disease. Thus, on the one hand, there were those who thought alcohol was a depressant rather than a stimulant, that it was not a food, that it did not promote but on the contrary retarded digestion, and that it was the cause of many diseased conditions. On the other hand, the great majority of the teachers of medicine continued to advocate alcohol as the best of all stimulants, and appealed to the experience of the wise and illustrious physicians, extending back to the dawn of history, as ample justification of their practice. How many had laid aside all prejudice, and had actually tested in a dispassionate and scientific manner the non-alcoholic treatment of disease? History was prone to repeat itself, and the end of venesection should be remembered. Dr. Didama then read a list of names of eminent members of the medical profession who indorsed the non-alcoholic treatment of disease, after a double experience—an ancient and a modern one—and closed with an earnest plea for the more general adoption of these views.

The Modern Treatment of Yellow Fever.—Dr. A. M. Fernandez de Ybarra, of New York, read this paper. He said that the best practice consisted in giving at the outset of yellow fever a cathartic, a full dose of castor oil being preferred to mercurials or salines. Quinine acted badly, and for the control of the fever it was much better to use moderate doses of aconite or digitalis. Jaborandi was used by some physicians, and it acted beneficially in a double way —*i.e.*, it promoted perspiration and relieved the congestion of the kidneys. Under no circumstances should opium be used in any form; it was extremely dangerous, owing to its effect upon the heart and kidneys. Care should be taken that the surface of the body was not suddenly chilled, as this would increase the visceral congestion. As a rule, alcoholics were not well borne, unless it might be iced champagne.

Committee on Hospital and Dispensary Abuses.—The following were appointed on this committee: Drs. F. H. Wiggin, S. B. W. McLeod, and Parker Syms, of New York; Dr. A. A. Hubbell, of Buffalo; and Dr. E. D. Ferguson, of Troy.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-Third Annual Meeting, Held in Louisville, Ky., October 5, 6, 7, and 8, 1897.

The association was called to order by Dr. Horace H. Grant, chairman of the committee of arrangements. Prayer was offered by the Rev. E. L. Powell, after which an eloquent address of welcome was delivered by Governor Bradley. Dr. William Bailey followed with an address on behalf of the local profession.

The president, Dr. Thomas H. Stucky, of Louisville, then delivered his address, in which he summarized the splendid work that had been done by the association.

Drs. Love and Wheaton offered resolutions against the present quarantining of Louisville by the State of Indiana.

SURGICAL SECTION.

Cases in Ophthalmic Surgery.—The first paper read before this section was by Dr. J. M. Ball, of St. Louis, entitled "Report of Some Cases of Ophthalmic Surgery." The author reported several cases of injury to the eye in which the proper surgical treatment proved satisfactory. One case of interest was a pseudoglioma removed by enucleation. The specimen was exhibited. Another was the case of a man, sixty years of age, who had been given sixty grains of quinine within twelve hours, in whom the next morning there was total blindness. A diagnosis of quinine amaurosis was made.

Dr. Wheelock inquired if there could not possibly be a syphilitic infection in the case of amaurosis reported, to which the author replied that such a possibility had been eliminated from the diagnosis.

Plastic Operation for Restoring Closed Lids.—Dr. K. K. Wheelock, of Fort Wayne, contributed a paper with this title. He reported a case in which an eye had been enucleated in 1881 in consequence of smallpox. An artificial eye had been worn for twelve years, when the socket had become so contracted that it was impossible longer to introduce the artificial eye. The technique of the operation for the restoration of the cavity to its normal size was described.

Dr. Stephenson said that these were always interesting cases. Those occurring as the result of burns usually gave the most trouble in fitting an artificial eye. Much could be done oftentimes by any method which would gradually stretch the tissues.

Dr. Wilder said that there was no more difficult class of work in ophthalmic surgery. The general surgeon should appreciate the necessity of preserving as much of the conjunctiva as possible. Most patients wanted to wear an artificial eye too soon after enucleation.

Dr. Wheelock, in closing, remarked that if he had a similar case to deal with he would operate entirely with the Thiersch grafts. These should be applied from the tip of the finger, so as to be adapted to any part of the orbit.

The Removal of Adenoids from the Vault of the Pharynx.—This paper was read by Dr. L. C. Kline,

of Indianapolis. The author stated that there was a great diversity of opinion regarding the use of anæsthetics for the removal of adenoids. The majority of patients could be operated upon with equally good results by the use of cocaine. The author preferred the gradual operation to that done at one sitting, for the reason that there was less danger of otitis and hemorrhage. A forceps which the author uses was exhibited. When an anæsthetic is employed a mouth gag is used. In tuberculous cases the application of ichthyol was very beneficial. Various astringents could be used with advantage, but surgery was the only sure relief.

Surgery of the Air Passages in Children.—Dr. J. Homer Coulter, of Chicago, followed with this paper. He considered the subject one of great importance, because of the high percentage of deaths from diseases of the air passages during childhood, because the respiratory and circulatory functions were being crowded to their vital capacity, and because reflexes in childhood were more prominent and frequent than in adult life. The parents of to-day should be taught that, with our modern methods, technique, and usually favorable prognosis, surgery in children was not the nightmare it formerly was. There was no longer any question of the bad effect of nasal obstruction upon adjacent organs. Any of the causes of nasal obstruction in children would tend to septum deflection in adult life, and if for no other reason the physician was bound to give them possible relief. Catarrhal deafness was almost always due to nasal obstruction. The entire field for pathological conditions of the nose did not lie in the postnasal space, nor was there any good reason why occlusion of the anterior chambers of the nose should not produce as many reflexes as does hypertrophy of Luschka's tonsil. Foreign bodies in the nose and throat and the method of their removal were then considered. The after-treatment was important, and could not often be left to parents with any degree of satisfaction.

Dr. Crile said that in all cases of surgery of the air passages an important point was the consideration of the "arrest area." Ordinarily the physician should not perform a cricothyrotomy unless it was necessary.

Dr. Thomas suggested that many diseases of the air passages in children were due to a systemic disturbance or to reflexes. Judgment to differentiate when to use surgery and when therapeutics, was absolutely essential.

Treatment of Wounds by the Open Method.—A paper on this subject was read by Dr. J. B. Taulbee, of Mount Sterling, Ky. Our present methods of treating amputations were different from those of a quarter of a century ago. A routine method was never a good one; hence each individual case was a law unto itself, both as to irrigation and the kind of drainage, and as to whether or not temporary drainage should be instituted.

Dr. Ochsner said that the least irritation to the tissues in abdominal wounds should always be observed. Large wounds would always heal primarily if there were lack of irritation of the tissues, exact coaptation, and the stitches were not drawn too tightly. The number of infected wounds in herniotomy was greater than in laparotomy, because the tissues were more greatly damaged.

Dr. Lawrence said that it was more reasonable to suppose a wound would be healthy if drainage was free. A properly cleansed private room at home with a good nurse was better than any general hospital. Silver-wire buried sutures would produce both sinuses and atrophy of the muscles.

Dr. Goldspohn stated that the only microbes that had indefinite life were those of the bacillus of tuberculosis and the gonococcus. Primarily aseptic wounds should be treated as such and not as open wounds.

Dr. Dunn said that when we did not have germs we could not have pus. In over two thousand abdominal sections which he had seen there had been no failure to secure primary union, and a stitch-hole abscess developed in only one case.

To Drain or Not to Drain.—Dr. Arch. Dixon, of Henderson, Ky., read this paper. For some time past drainage after abdominal section had been growing less and less in favor. There were wounds which required drainage, and others which did not. Aseptic wounds did not require it, but contaminated or infected wounds did. The author reviewed the arguments against the use of drainage in the peritoneal cavity. Drainage was not effective in removing infection; infection might occur through the drainage tube. The removal of the tube was painful, bladder complications were possible, hernia might result, and frequent removal of the tube was necessary.

Dr Goldspohn called attention to the two methods of abdominal operations—one in which the smallest possible opening was made, and the other in which a large wound was made. He pointed out the advantages claimed for each method of operating.

Dr. Cordier said that if two cases exactly alike were taken, and the operation, surroundings, and care of each be identical, one drained and the other not, we would almost invariably obtain more satisfactory results in the case in which drainage was employed.

Hysterectomy.—Dr. F. F. Lawrence, of Columbus, read a paper with this title. In what cases is hysterectomy justifiable? We must consider: (1) How many would have died without it; (2) who many would have been hopeless invalids without it; (3) how many could have been cured by other means; and (4) the remote conditions or reflex results in those upon whom the operation has been performed. Hysterectomy was ordinarily performed for cancer, pyosalpinx, fibroma and myoma, tuberculosis, and prolapsus. Hysterectomy for cancer was of doubtful utility, but when necessary should be done by the abdominal route. In the case of pus tubes the operation should be limited to those in which the walls of the uterus were the seat of the disease. Simple adhesions were not sufficient grounds for the performance of this operation. Small fibroids involving the lower segment of the uterus only should be treated tentatively. If the small fibroids were in the body of the uterus, they should be treated either by curetting, by removal of the tubes and ovaries, or by hysterectomy, as the case demanded. If small fibroids occurred near the menopause, curettage with electricity was sufficient. For enlarged fibroids after the menopause, hysterectomy was the only thing to be considered. In myoma or tuberculosis, this operation was likewise the only thing to be resorted to. By removing the ovaries and tubes, all of the diseased tissue was not taken away. Any method of operating was to be judged by the safety from complications, by the preservation of a firm pelvic floor, by the facility of operating, and as it afforded the best satisfaction and general results to both patient and operator.

Dr. Goldspohn opposed the removal of the uterus for septic disease alone in every case. The vaginal route should be more appreciated by American operators.

Dr. Ochsner said that while his experience with hysterectomy had been favorable, yet he was becoming more and more cautious about advising its performance. In one case he advised the operation, as he considered the case beyond the help of even this operation. The woman was treated tentatively, had since given birth to two children, and was now healthy.

Dr. Newman said that better results would follow a perfected technique.

Pelvic Disease without Local Symptoms.—This paper was read by Dr. Henry P. Newman, of Chicago. The speaker said that pelvic disease of an aggravated type was often present without noticeable local symptoms; that reflex symptoms began in mere functional disturbance, and might become so serious as to endanger the life and health of the patient, and give rise to misdirected treatment which did not recognize the causes of the real trouble. It was necessary to understand the relative importance of pelvic irritation, and of certain obstinate and severe affections of more distant organs. This was very essential to a correct diagnosis in many cases. In all cases of chronic invalidism in the female, failure to exclude pelvic disease, in the same manner as we excluded diseases of the other important organs, was unscientific and reprehensible. The cause of medicine would be advanced when practitioners made comprehensive diagnoses.

The Diagnosis of Surgical Diseases of the Kidneys, Bladder, and Prostate.—Dr. Bayard Holmes, of Chicago, contributed this paper. The author called attention to some methods of diagnosis of special value, and related at length his experience in their application, demonstrating by means of the Kasper cystoscope his method of catheterizing the ureters. He further demonstrated that the kidney could be exactly localized by auscultatory percussion.

Diagnosis by Inspection of the Urinary Tract.—Dr. Joseph R. Eastman, of Indianapolis, read this paper. The use of the cystoscope was particularly important in the male. Its value in diagnosticating vesical calculus, foreign bodies, neoplasms, and pathological conditions resulting from gonorrhœa, locating fragments after litholapaxy, etc., was very apparent. In the female its range of usefulness was still wider and its application more simple. The author described and demonstrated in a clear manner the difficulties and technique of catheterization of the ureters.

Dr. Cordier said he had recently made some experiments with the *x*-rays in bladder work. He had, by placing a small photographic plate in the vagina and the tube above the abdomen, secured very excellent photographs. In the male the plate could be placed in the rectum and similar results secured. Foreign bodies or calculi could thus be positively detected.

Primary Tuberculosis of the Rectum, with Report of Cases.—Dr. Leon Straus, of St. Louis, read a paper on this subject. Tuberculosis of the rectum was a surgical disease. A thorough microscopical examination must be made in every case of suspected ulceration. The author reported four cases of removal of the ulcerated rectal tissue and described his operation. Recovery followed in all of the cases but one. His conclusions were that: (1) Primary tuberculosis of the rectum is not so infrequent as is generally supposed. (2) It is surgical. (3) It cannot be diagnosticated positively and invariably by the usual clinical symptoms; the microscope must be employed. (4) Local treatment will not cure these cases; they can be cured only by thorough curettage or by excision, or by both. (5) Some of the most hopeless cases are cured by repeated operations. (6) All suspicious cases should be subjected to the microscope. (7) We have sufficient evidence that the cases reported are cured.

Diseases of Rectum and Sigmoid as a Factor in General Disturbances.—Dr. J. R. Pennington, of Chicago, read this paper. Undoubtedly various authorities are agreed that the *materies morbi* of a large number of somatic, mental, and nervous diseases have their origin somewhere in the gastro-intestinal tract. At just what point in the canal is a mooted question. The importance of the rectum and sigmoid in many auto-intoxications is entirely overlooked and the consequent primal defect not located.

Treatment of Hernia in Old Men.—Dr. A. J. Ochsner, of Chicago, read the paper. It was a well-known fact that hernias in men become more troublesome after the age of fifty, due to relaxation of tissue, a tendency to obesity, and lowered vitality in general, according to most authorities; but the author was convinced that the more important cause was the pressure exerted in evacuating the bladder and rectum, or the presence of an enlarged prostate. The author described his operation for the radical cure of hernia in connection with castration for enlarged prostate. In cases in which there was simply hypertrophy, the gland subsequently decreased in size very rapidly, affording much relief. If the surgeon had perfect control of his methods, securing perfect asepsis, the operation was perfectly safe. It relieves the patient of much discomfort, and every argument in favor of operation for the radical cure of hernia was applicable to the operation for resection of the spermatic cord for the relief of conditions due to enlargement of the prostate gland. It was as yet too early positively to determine whether or not the favorable results obtained by the author in his cases would be permanent, but he had every reason to believe that they would.

Postoperative Hernia in Appendicitis.—Dr. Robert T. Morris, of New York, read a paper on this subject. Operators for appendicitis were now using a much smaller incision than formerly, in order to avoid the unfortunate effects of a hernia. These hernias were caused by the fact that the lines of muscle traction at this point were different in different muscles. A pad over the seat of operation induced hernia by bringing on absorption of the new connective tissue as it was being formed. The margin of each muscle should be separated with the greatest care in operating; care should likewise be taken in dividing the peritoneum. In closing the wound each different layer of muscular tissue, as well as the peritoneum and fascia, should be united with the same tissue from which it was separated at the beginning, so that the lines of muscular traction would not be disturbed, and hernia was not so likely to be produced. No bandage or pad should be applied. The patient should be kept in bed for at least twenty-one days following the operation.

Dr. John Young Brown, of St. Louis, made some remarks on appendicitis, in which he said conservatism had given place to knowledge in this disease. This knowledge was sufficiently comprehensive and accurate to afford a satisfactory working basis. Infectious appendicitis should be isolated, for the same reason that a case of diphtheria was isolated.

Dr. Morris, of New York, said that making a date to operate in a case of appendicitis was certainly undesirable. The surgeon could not always wait until the third day. Rigor meant that toxins were entering the circulation and producing an impression upon the sympathetic system.

Tuberculin in Dermatology was the title of a paper by Dr. A. Ravogli, of Cincinnati, in which the author drew the following conclusions: 1. Tuberculin is a valuable aid in dermatology, both as a diagnostic and therapeutic measure. 2. In lupus it acts remarkably well as a systemic treatment, particularly in conjunction with other means for the purpose of reducing infiltrations. 3. After a large number of injections he has never had any bad effects. 4. Old tuberculin has given him more marked reaction, both general and local, than the new. 5. In cases in which ordinary remedy had an influence, tuberculin promptly caused a disappearance of the eruption, healing of the ulcerations, and a general improvement in the condition. 6. If relapses occur after the use of the remedy has been discontinued, we are not justified in blaming the remedy therefor. 7. To insure recovery, tuberculin must be used in small doses for a long time at short intervals.

Mothers and Daughters.—Dr. B. Sherwood Dunn, of Boston, read a paper with this title, in which he stated that higher education, according to many authorities, was detrimental to motherhood. He pointed out some of the fundamental errors in modern education and the training of girls, showing that although on the care of our children depended their lives, their moral welfare or ruin, yet in our modern system of education not a word of instruction relative to the treatment of offspring was ever given to those who would become parents. He considered at length the necessity of more careful physical training of girls. Labor, exercise, and food were considered important elements in their training, and above all they should have a proper knowledge of the physiological functions peculiar to their sex. Parents must decide themselves as to how these important points should be taught.

Dr. Joseph Eichberg, of Cincinnati, read a paper descriptive of cases of typhoid fever treated with cold baths.

Further Observations in the Use of Hydrogen Dioxide in the Treatment of Blepharitis Marginalis.—This was the title of a paper by Dr. S. C. Ayres, of Cincinnati. This disease unchecked produces gradual destruction and atrophy of the hair bulbs from ulceration. Mercurial ointments have long been used, and are well adapted to some cases but irritating to others. An alkaline wash is very beneficial in softening the crusts, but in hydrogen dioxide the author thinks we have a remedy which both softens and dissolves. After using the remedy, with a dressing probe or scoop the crusts can be lifted off. The dioxides will always be a valuable adjunct to other rational measures in the treatment of this disease.

Dr. Max Thorner, of Cincinnati, said he had used this remedy extensively and had seen the results from its use in Dr. Ayres' hands, and almost invariably he had most satisfactory results. However, in recent years the remedy had fallen into disuse.

Chronically Diseased Tonsils.—Dr. H. W. Whittaker, of Columbus, read a paper on this subject. Seriously diseased tonsils are frequently underestimated in importance and left untreated, when they are undoubtedly very injurious to general health. In chronic disease of the tonsils there may be either hypertrophy, hyperplasia, or atrophy. Hypertrophy of the tonsil is found in the child; hyperplasia in the adult. The causes which induce chronic tonsillitis may be predisposing or exciting. Among the former the most important is heredity; among the latter are diphtheria, scarlet fever, and the exanthemata. The author gave a comprehensive description of the symptoms usually present. Prognosis is good, providing excision is properly performed. The voice is vastly improved both in tone and quality after excision of the tonsils, and no deleterious sexual changes or perversion will ensue. In the treatment it is necessary to consider the hygienic, prophylactic, local, constitutional, and surgical measures. The details of each were noticed and thoroughness was insisted upon.

Hypertrophied Faucial Tonsils.—Dr. J. F. Barnhill, of Indianapolis, followed with this paper. It was strange that the laity still had absurd notions relative to the functions of the various tonsils. The system suffered little or nothing from ablation of normal glands. The author's classification of cases was: (1) those in which the patient claims never to have suffered inconvenience from the tonsils; (2) those in which there is quinsy or tonsillitis one or more times a year; (3) a small, flat, yet pathological gland. In all cases the diseased crypts should be cleared out. The patient was a most valuable assistant. The bad results of pathological tonsils were enumerated, and they were stated to be a cause of reflex neuroses and to act as obstructive bodies, as absorbents, and as auto-infectious bodies. Various methods of treatment and removal of the tonsils were considered, and the merits of each were pointed out.

Insanity of Adolescence.—Dr. Frank P. Norbury, of Jacksonville, read a paper on this subject, in which he drew the following conclusions: (1) Adolescent insanity is a pure psychosis, dependent upon hereditary factors and acquired conditions which especially inhibit the higher psychical centres and later the sensory motor functions of the cortex. (2) The vasomotor and trophic centres are involved in it. (3) The sympathetic nervous function is disturbed, from which it is apt eventually to lead in the female to suppressed menstruation, or even excitation, producing nymphomania. (4) Masturbation is a complication which in the male is apt to cause reflexes. (5) There is no period in life more important than adolescence.

The Treatment of Cerebro-Spinal Syphilis.—Dr. A. E. Sterne, of Indianapolis, read the paper. In the treatment of syphilis of the brain and cord, the ordinary therapy is wholly inadequate, if not entirely wrong. The dose is too small; the potassium salt is inferior to the sodium salt, particularly in large doses. The syphilitic lesions of the brain and cord may involve the meninges, the brain and cord tissues with gumma formation, the bony parts, and the blood vessels. The author drew attention to three important points in diagnosis and therapy: First, in producing the reflex with the percussion hammer there occurs at the moment of the hammer blow a second prolonged contraction across the muscle. Second, the iridic reflex to light is sometimes difficult to determine and is not always present. The third point is wholly prognostic in value, and relates to capillary pulsation; when this occurs, it indicates high arterial tension and serves as a guide in the use of heart stimulants.

The Motor Neuron in Practical Diagnosis was the title of a paper by Dr. Hugh T. Patrick, of Chicago. The author made a concise statement of the more practical relations of the neurons of the motor tract. A neuron, as he explained, is simply a nerve unit, and the motor tract is made up entirely of two distinct sets of neurons, an upper and lower. A lesion of either set causes paralysis, but the customary accompanying symptoms are radically different in the different groups. The *rationale* of these differences was briefly pointed out, and it was explained that in a lesion of the upper neurons the paralysis is spastic, accompanied by increased deep reflexes, no atrophy, and no change in electrical reactions. On the other hand, in a lesion of the lower neurons, the accompanying and distinctive signs are flaccidity, loss of deep reflexes, atrophy, and reaction of degeneration. It was further stated that it makes no difference whatever which part of the neuron is affected, the result in all respects being exactly the same.

Tobacco Neuroses.—Dr. Zenner, of Cincinnati, read a paper on this subject. In very many instances tobacco is only one of the many causes of the existing malady. Among the other factors often conjoined with tobacco and which make the diagnosis more difficult, are alcohol, coffee, mental strain, worry, etc. Syphilis also often plays an important part. The neuroses traced to tobacco are functional diseases of the heart, amblyopia, tremor, vertigo, neurasthenia, some forms of neuralgia, rarely angina, and the lesser nervous disturbances, epilepsy, and various psychoses; even paresis has been attributed to it, although without sufficient reason in every case. The treatment is entire abstinence from the use of the weed. The mere lessening of the amount usually fails altogether. Frequently entire abstinence for a year or more permits a return to the use of tobacco in moderation without harm.

Penetrability of Vaporized Medicaments in Air Passages.—A very instructive and exhaustive paper was read by Dr. Homer M. Thomas, of Chicago, entitled "Experimental Work on the Penetrability of Vaporized Medicaments in the Air Passages." Do vapors enter the alveoli of the lungs? All observers thus far have questioned such a possibility. The greatest difficulty has been in the mechanism of the instruments for vaporization, in that they have failed to break up the oil in sufficiently fine particles for it to enter the alveoli. The author related in detail the results of his experiments, mostly on animals, during the past two years, and gave his reasons for believing that under proper conditions the medicament will enter the healthy lung, even to the alveoli. A variety of microscopical slides were exhibited, taken from the lung of a patient in whom inhalation had been practised shortly before death, which plainly showed the oil globules in the alveoli.

Dr. C. A. Johnson, of Chicago, followed with a paper on the same subject. He related his experience in the use of the instrument in forty tuberculous cases, and directed attention to the point that the solution employed must be a weak one, as too strong a solution produces irritation and consequent hypersecretion. The first symptom of improvement was relief from the dyspnœa, and the next a lowering of the temperature.

Epistaxis in the Most Serious Form, with Report of a Case Necessitating Ligation of the Common Carotid.—Dr. Max Thorner, of Cincinnati, the author, said that in using the term epistaxis, reference was made to hemorrhages in which blood comes from the nose, and those cases in which it merely passes through the nose. In the latter category is included bleeding from the pharynx, naso-pharynx, the accessory cavities, larynx, lungs, and stomach, as well as in cases of fracture at the base of the skull. The author considered serious cases only, those in which the ordinary styptics fail to check the hemorrhage. He referred to four cases in which the radical operation of tying one or both carotids was practised, two of which proved fatal. The paper closed with a reference to a case in his own practice. It was that of a man struck with an iron ring across the bridge of the nose and right side of the face. Unconsciousness and profuse bleeding from the nose followed. The patient was removed at once to the hospital and the nose plugged. During the next eighteen days the nose was tamponed repeatedly both anteriorly and posteriorly, but each time after removal of the tampons the hemorrhage started afresh within seventy-two hours. The patient becoming almost exsanguinated, with high pulse and increased temperature, an operation was decided upon. The common carotid was ligated. The hemorrhages did not recur, and the patient was discharged one month after the operation.

Scoliosis.—Dr. William E. Wirt, of Cleveland, contributed a paper on the treatment of scoliosis, in which he referred to the use of dry heat at high temperature for the treatment of this condition. He recalled the fact that he had originated this treatment three years ago, and had been experimenting extensively along this line continuously ever since. He explained in detail the apparatus used to inclose the heat about the joint, and by reference to several well authenticated cases showed the certain value of dry heat in the therapeutics of scoliosis.

The Thyroid Glands.—Dr. I. N. Love, of St. Louis, spoke on "The Thyroid Glands from a Clinical Standpoint." He gave an interesting historical review of serum therapy, and particularly of thyroid therapy, and drew valuable deductions from his experience with it.

Some Phases of Extra-Uterine Pregnancy.—Dr. A. H. Cordier, of Kansas City, read a paper entitled "Some Phases of Extra-Uterine Pregnancy." This condition was not recognized and diagnosticated as it should be by the general practitioner. The application of common sense and good judgment was the best guide to the successful termination of ruptured tubal pregnancy. If a blood vessel was injured and bleeding it should be tied. The diagnosis was usually not very difficult. A very important point was the menstrual history, and this should be thoroughly investigated. The pathology of these cases was of little value at the bedside. A tube having once ruptured would continue to give trouble. The dangers of the condition far outweighed the dangers of good surgery employed in these cases. Operation should be performed at the earliest possible moment. Clots did not always form. No case was devoid of danger until the bleeding vessel was firmly tied.

The Treatment of Suppurating Fistulous Tracts.—This paper was read by Dr. E. J. Senn, of Chicago. The primary dressing should not be disturbed for four or five days, when it is removed and repeated if necessary. Nitrate of silver or other caustics should not be used, as the granulations are only superficially destroyed, leaving a necrotic area, which should be avoided. If the granulations are persistently sluggish, the wound should occasionally be packed with gauze saturated with balsam of Peru, as this agent stimulates the regenerative capacity of embryonal cells without impairing the vitality of the surrounding tissues. In the author's hands most obstinate fistulæ have yielded under the treatment suggested when previous antiseptic irrigation over estimated periods of time proved of no value.

One of the pleasant features of the closing scenes of the meeting was the presentation of some handsome pieces of furniture to Drs. Stucky, Grant, and Tuley, on behalf of the exhibitors present, in recognition of the work done by these gentlemen for the success of the meeting.

Amendments to the constitution, enlarging the duties of the secretary and providing a salary for his services, were adopted; action was also taken with regard to the permanent preservation of the transactions of the association.

A resolution rescinding the action previously taken relative to the reported quarantining of Louisville by the State of Indiana was unanimously passed.

Officers Elected.—The following officers were elected: *President*, Dr. John Young Brown, of St. Louis; *Vice-Presidents*, Drs. A. J. Ochsner, of Chicago, and A. P. Buchman, of Fort Wayne; *Secretary*, Dr. Henry E. Tuley, of Louisville, Ky.; *Treasurer*, Dr. Charles A. Wheaton, of St. Paul. Place of meeting, Nashville. Time, second Tuesday in November, 1898.

After adopting resolutions of thanks to the various committees, the association adjourned.

For Injection in Small Dose, for emaciation, cachexia, etc., after lingering chronic diarrhœa, just as in the adult in tardy convalescence, postoperative shock, and neurasthenia, Cheron's solution:

℞ Ac. phenic.,
Sod. chlor.,
Sod. phos.,
Sod. sulphat. ..... āā 1 gram.
Aq. dest. ..... 100 "
M. S. Five grams injected twice daily.

Debilitated children often increase in weight under this medication, but if continued too long the injections produce a condition of sleeplessness, unrest, with crying, etc., and may cause true lymphatic engorgement.—Therapeutic.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE GENERAL MEDICAL COUNCIL ELECTION—SIR W. FOSTER—MR. HORSLEY—TYPHOID AT MAIDSTONE—INCREASE OF THE EPIDEMIC—WATER SUPPLY POLLUTED—DR. WASHBOURN FINDS THE BACILLUS—A DANGER TO EAST LONDON SUPPLY—DR. PARKES ON SANITATION—MEDICAL SOCIETY OF LONDON.

London, October 1, 1897.

THE contest for the seat in the Medical Council so inauspiciously vacated by Dr. Rentoul is creating unusual interest. In London and the large centres the excitement is rising as the day for decision approaches, but it is feared that in country districts the apathy of the profession may prevent the poll being as heavy as could be wished. The indifference that has marked some elections has prevented some reforms and has rendered governments unwilling to enlarge the powers of the council. The voting-papers will be issued to-morrow and must be returned on or before the 9th. They will be counted on the 11th, and the result stated at a meeting on the 15th. Mr. Jackson has withdrawn in favor of Sir Walter Foster, M.P., M.D., who on returning from the meeting in Canada immediately issued an address. His views are pretty well known, as he was a member of the council for ten years and was not willing to come forward last year for a third term. This in some degree is against him, as is also his close association with the British Medical Association and the manner in which he was first nominated by that body. On the other hand, Sir Walter's experience in parliament is a valuable qualification, and in the House of Commons he has been a consistent advocate of professional rights. As parliamentary secretary to the local government board, he gave general satisfaction and was able to further professional interests. Should the Liberal party regain power within a moderate period, he might obtain higher office. On Wednesday there was an influential meeting in London to support him, in which he stated his opinions and replied to questions—in fact, was subjected to a rather unpleasant and personal cross-examination. On a voté being taken, his supporters were fifty-four against seven.

To-night there is to be a meeting of Mr. Victor Horsley's supporters at the West End and another in the Northeast of London, and to-morrow a meeting at Norwich. His candidature has been received with such favor that he might have confidently looked for success, but the appearance of Sir W. Foster in the field quite alters the conditions. The contest will most probably lie between these two. I have previously stated the names and claims of the other candidates. Mr. Horsley's scientific position and Sir W. Foster's political opportunities seem to be the points most talked about.

The typhoid, fever epidemic at Maidstone, announced in my last, has spread during the week with such rapidity that it is becoming a national calamity. More than a thousand cases are notified, and that in a population of a little over thirty-two thousand. In fact, at 6 P.M. yesterday eleven hundred and forty cases had been notified. The previous day the number reported was nine hundred and fifty, and there is no sign of the rapid rate of increase diminishing. Of course all business in the town and district is practically suspended, and the one thought of the survivors is how to arrest the plague. The hospital accommodation was of course insufficient to cope with such an emergency, but other buildings have been fitted up in the greatest haste. Thus the Salvation Army placed its barracks at the service of the sanitary committee, as did the trustees of the Wesleyan schools. Boiled milk, soup, and other supplies are being freely distributed, and a large number of nurses has been engaged, while more than one hundred young men are working as night nurses in order to give some rest to the friends and attendants of the patients. On the advice of the government inspector, three substations have been opened by the guardians, at which the nurses can obtain all necessaries for the patients on applying for them.

The origin of this deadly epidemic has been traced to pollution of one of the springs from which the town draws its drinking-water. The medical officer of health seems to have been alive to the possibility of this contamination, and at an early period to have fixed on the source of danger and brought the matter under the notice of the authorities. The incriminated springs were unprotected in open meadows, where hop-pickers had been allowed to encamp, and it has since been ascertained that cases of typhoid had occurred among them. To-day the water company is discussing the necessity of cutting off all the supply from these springs. It seems there was some difficulty in obtaining enough water from the others, but a gentleman of the neighborhood has placed at the disposal of the authorities some additional springs of undoubted purity. Surely at the very first the suspected supply should have been shut off, and there will be no little discussion as to where the blame of not doing so must rest. Dr. Washbourn was called in as a bacteriological expert, and has found the bacillus typhosus in the water of the suspected springs.

A terrible object-lesson is thus before the country, and the newspapers are full of details and suggestions. And yet very little attention has been paid to a statement that in East London boys and men are in the habit of bathing in one of the tanks of the water company. This must be rendered impossible, for the danger is obvious, and the company ought to take immediate measures to protect its water from such a source of danger and pollution.

Dr. L. Parkes gave a lecture on Monday at the Parkes Museum, on the "Outcome of Sanitation," in which he showed how much sanitary science has done for this country.

Next week the work of the Medical Society will begin, when Dr. Sansom, the incoming president, will give an address on "Nervous Disturbances of the Heart," and Mr. Anderson will read a paper on "John Ardern, the Father of English Surgery."

OUR PARIS LETTER.

(From our Special Correspondent.)

DR. LAPORTE'S CASE—SYMPATHY FOR HIM—THE PRACTICE OF MEDICINE—OVERCROWDING AGAIN THE SUBJECT OF AN ESSAY—TREATMENT OF CORYZA—VOMITING DURING PREGNANCY—INCREASE IN THE PRICE OF BREAD, ETC.

Paris, September 25, 1897.

THE unfortunate case of Dr. Laporte, about which I wrote you in my last, is arousing considerable sympathy, not only among the laity but more especially among the medical profession. It seems that the doctor was absolutely without the means to procure the instruments (forceps) necessary in such cases, and that in the operation on Madame Fresquet the packer's needle was used in place of the basiotribe. For his defence Dr. Laporte cites the authority of Penard and Abelin, who have published a much-appreciated treatise on obstetrics, and who state very judiciously, at least so

affirms the accused, that if the accoucher or doctor has not at hand the necessary instruments he is justified in using such objects as they may deem best adapted to the accomplishment of their task. Other and distinguished surgeons have done the same, only they were successful. If the operation in this case had succeeded perfectly and the mother had made a good recovery, Dr. Laporte would have been a very clever man instead of being in prison. As there was also no criminal intent whatever, but evidently only a humanitarian effort to deliver the woman and alleviate her sufferings, numerous physicians are taking active steps to have the judge, M. Bertulos, place Dr. Laporte at liberty provisorily.

The question of mental unsoundness has also been raised, but Dr. Laporte is considered as absolutely responsible for his acts, and he himself assumes the responsibility, stating that while he used instruments such as works on surgery do not recommend, he was constrained to do so by the urgency of the case.

The governmental authorities are still at work regulating the practice of medicine, determined to prevent illegal exercise, and the following details of an official act will be read with interest: By decree, the law of November 30, 1892, on the practice of medicine in France, is rendered applicable to the colonies, excepting protectorate countries. There are, however, certain specifications, of which the principal are: 1st, The list of epidemic diseases, the divulging of which does not engage professional secresy, shall be drawn up by order of the minister of the colonies in accordance with the opinion of the Academy of Medicine and that of the consulting committee of hygiene of France. The declaration should be made by every or any civil or military doctor, health officer, indigenous doctor, or *sage femme* practising in the colonies. 2d. In French colonies in the Indies is maintained an institution for indigenous doctors. Further, where it is deemed necessary the practice of medicine may be authorized by decree, and special schools for indigenous doctors shall be established under the same regulations.

The right to practise dentistry, in conformity with the provisions of article 82, is given to every dentist proving that he was inscribed on the patent roll on January 1, 1897.

The work at the École de Médecine just now is not exactly of a scientific character and is limited to getting things in order for the beginning of the scholastic or academic year next month. One of the most important changes is the new library. The transfer from the old to the new library having been completed some time since, many thousands of volumes are now in their places on the shelves of the new library, which is quite imposing in appearance and is provided with long tables for the use of professors, students, and general practitioners.

Among recent publications is one that only accentuates what has been several times referred to in my letters from Paris, viz., the overcrowding of the medical profession. The title is "Obstruction [Encombrement] and Depreciation of the Medical Profession," and the author is Dr. L. Grellety, consulting physician at Vichy.

The abortive treatment of coryza, a disease or the commencement of a disease so common at this time of the year, is attracting professional attention. Dr. Maurel, of Toulouse, suggests placing small wads of iodoform cotton in the nostrils, which he finds occasions neither inconvenience nor irritation. He also recommends iodoformic vapors, placing them in direct contact with the staphylococci of the nasal cavities. The coryza heals rapidly under their influence, and, what is more important, the descending bronchitis that so often follows is prevented or reduced to a minimum. Dr. Maurel, however, wisely adds that in order to obtain these results the coryza must be taken at the very beginning. In my own experience I have never found anything better than a snuff consisting of equal parts of subnitrate of bismuth, chlorate of potassium, and sulphate of quinine.

Professor Tibone, of the Faculty of Medicine of Turin, finds the best and most rapid way of stopping persistent vomiting during pregnancy to be hypodermic injections of cocaine given in the epigastrium. He recently tried it very successfully in a number of cases in which hypodermic injections of morphine had had no effect. Thanks to these injections of cocaine in doses of one centigram or about one-fifth of a grain, repeated once or twice a day, almost immediately after meals, the patients were able to retain what they had eaten, without the cocaine having any bad after-effects upon either the pulse, respiration, or temperature. Little by little the general condition of the patients improved, the weight of the body increased considerably, and the vomitings did not recur even after the injections of cocaine had been stopped.

A propos of the case of Dr. Laporte, who has not only some of the leading newspapers but the profession and public sympathy with him, I quote from a recent "Précis d'Obstetrique" by no less men than Drs. Ribemont-Dessaigne and Le Page, of the Faculty of Paris, a standard work (see page 1,215). There is, so to speak, no instrument that has not been used to open the cranial cavity of the fœtus. Numbers of doctors, not having at their disposal special instruments, have used what they had at hand—kitchen knives, scissors, etc. There is therefore no lack of authority for performing craniotomy with whatever instrument may, in the judgment of the physician, be deemed most fitting in want of the regular instruments prescribed for that purpose and in cases of great and immediate urgency.

The annual meeting of the Anglo-American Continental Medical Society takes place next month. The date is October 12th. The question of the formation of a branch society on the Rivièra is still pending.

Just now many of those physicians who practise in the south of France and on the Rivièra are passing through Paris—our confrère, Dr. Linn, of Nice, among others, is returning thither. Dr. Linn's book on the health resorts of Europe has taken a well-merited place as authoritative in climatological literature. He has observed cases of catarrhal affection cured by a simple sojourn in the dry air of Nice.

The rise in the price of bread, which falls heavily upon the Paris poor, has been caused by the unusually bad year for cereals. All the railways, in a spirit of alleviation, have reduced their tariffs for the transportation of cereals.

Yesterday was the second anniversary of Pasteur's death, and it was fittingly remembered at the Institut.

THE PULMONARY ORIGIN OF THE CREPITANT RÂLE.

To the Editor of the MEDICAL RECORD.

SIR: "If we are to draw conclusions, our methods must be accurate, our deductions must be logical, they must stand the test of careful scientific analysis, they must conform to known physical laws." These are the exact words used by Dr. Louis H. Jones, in his article supporting the interpleural origin of the crepitant râle, which appeared in the issue of the MEDICAL RECORD of June 5, 1897. I fear, however, that the above just considerations can in no wise be applied to the paper with which the doctor would have us join him in considering the crepitant râle of interpleural origin. I heartily indorse the doctor in the sentiment expressed in the closing sentence of his article, that

we should not accept all new teachings without investigation, but likewise object to the resuscitation of individual opinions that have justly never received any serious consideration from scientific medical men.

Before beginning my defence for the pulmonary origin of the crepitant râle, let me say that the point at issue is not whether we can have a real pleural rub not to be distinguished from a crepitant râle, but whether or not this râle is of pulmonary origin. We know that at times we may have a pericardial rub indistinguishable from a heart murmur, yet this does not establish its endocardial origin. So, therefore, Dr. Jones' quotation from Osler has no direct bearing on the subject.

The study of Leaming's work on the lungs leads me to believe that his enthusiasm led him to fit the cases to his theory rather than the reverse. In all his post mortems in which he had heard crepitant râles, he found signs of either recent or of adhesive pleurisy, but he also found presence of pneumonia or of phthisis; therefore the presence of crepitant râles prior to death could be explained either by the pneumonic or tuberculous process without the presence of the pleural condition. Had he in any of his post mortems been able to demonstrate undoubted crepitant râles with only pleural inflammation, then his opinion would have been greatly strengthened. We, on the other hand, who hold the opposite view, can present cases in which crepitant râles were present, and in which at the post-mortem table no evidence of pleural involvement was found complicating the pneumonia. These cases are uncommon, but they do exist. This is particularly true of central pneumoniæ.

Leaming states (page 23) that "central pneumonia without interpleural plastic exudation is unaccompanied by râles, either crepitant or subcrepitant;" but in contradiction to this I quote from the article by Juergensen on "Pneumonia," in Ziemssen's Encyclopædia, page 84: "Even in central inflammation of the lungs the râle may often be detected; but Laennec makes too sweeping a statement when he says that a comparatively unpractised ear can discover by the crepitation the existence of central infiltrations no larger than an almond." If the crepitant râle depended for its existence on the movement of one layer of pleura on the other, why would it not be present at times during expiration, as is frequently found in real pleural friction sounds, and why should we not hear it during the stage of complete consolidation, when the quantity of exudate is greatest in amount?

Dr. Jones states that the crepitant râle is sometimes heard in this stage; this is undoubtedly the case, but then it is due to the fact that some vesicles are not quite full of exudate, or to the presence of inflammatory œdema in the vicinity of the pneumonic area.

In support of this I again quote from Juergensen: "Over the parts which have become solid with infiltration, this sign is absent," etc. Furthermore, we all have seen cases of pneumonia in which during the course of the disease either in the adjoining lobe of the same side or on the opposite side have developed pure crepitant or subcrepitant râles, and yet on post-mortem nothing but a little hypostatic congestion or œdema was found. It has been observed that if a patient lies on his back for a short time or sits up in bed in a cramped position, it is possible to hear distinctly over the lower parts of the lung posteriorly typical crepitant râles, which disappear at once after a few deep inspirations. This is due to a temporary atelectasis, and the râles are produced by the air separating the collapsed vesicles. Here the pleura cannot be involved. We know that in the real friction rub the phenomenon is best heard over the more movable parts of the lung, and that after a few deep inspirations it often disappears. But this is not so in the case of the crepitant râle. The supporters of the intrapleural origin claim that the sound is heard directly beneath the ear, and therefore originates in the pleural cavity. Is not the râle generated in the vesicles immediately beneath the visceral layer of pleura just as close to the ear; and furthermore is not the lung in this state of consolidation in excellent condition to convey to the ear most distinctly those râles generated more deeply in the lung? Is it not for this reason that Skoda called these râles "consonating râles"?

I hope these few arguments will succeed, if not in convincing the readers where the crepitant râle is generated, at any rate in persuading them that the râle is not of intrapleural origin. Let us go a few steps farther and attempt to establish the site of origin of this disputed râle. Dr. Jones says that crepitant râles cannot be produced by the separation of the walls of the air vesicle, for, he says, atmospheric pressure prevents the collapse of the vesicle and the residual air prevents the tidal air entering the smaller bronchial tubes in mass. Regarding this latter opinion I will say that physiology teaches us that the residual air is in excess of the tidal, and it constantly occupies the bronchioles and the air vesicles; but is it not this very air that rushes in to dilate the air vesicles during an act of inspiration pushed onward by the means of the tidal air entering the trachea and bronchi? During expiration a portion of this same residual air is forced out into the bronchioles again, and in the mean while constant exchange of gases according to the laws of diffusion is going on. Leaming himself says, on page 20: "In unhurried healthy respiration the air enters in a body to the bronchi as far as the third or fourth division, when it becomes instantly mixed with the residual air, becoming a component part of it, and by its addition equally dilating the distensible true respiratory system." Regarding the atmospheric pressure preventing total collapse of the air vesicle, I concur, but this does not prevent the air vesicle becoming filled with exudate thrown out from its walls. This exudate, in my opinion, is at first only small in amount, so that when the intrapulmonary pressure is lowered by an inspiratory act the air rushes in, as explained above, until the pressure rises sufficiently to overcome the cohesive power of the exudate, distending the vesicle and giving rise to the crepitant râle. This of course would occur toward the end of inspiration when intrapulmonary pressure is greatest, and it is exactly at this period that crepitant râles in pneumonia are best heard. It may be objected to this opinion by those holding the other view that, if such is the case, why do we not get the same condition in the so-called stage of complete consolidation? The reason is that in this latter stage of pneumonia the vesicle is overfilled with exudate, so that it might be considered as distended by the exudate as it would be in health by air. This can be proved on post-mortem by the fact that the lobe affected with pneumonia is larger than normal, so much so that the imprints of the ribs are on its surface; also by the fact that the pressure of the exudate on the capillaries of the alveoli of the lungs is sufficient to produce ischæmia of the lobe. Furthermore, the exudate becomes more solid in the alveoli, and the air would tend to press the exudate more firmly against the wall of the vesicle. Wintrich has succeeded by auscultating the excised lung of an animal to hear râles distinctly when air was forced into it.

This is briefly what I have to offer in objection to the intrapleural origin of the crepitant râle; I sincerely hope it carries some conviction with it to those who have been patient enough to follow to the end the pathological and clinical facts mentioned in my discussion.

Guido E. Cagliéri, B.Sc., M.D.

520 Montgomery Street, San Francisco.

TAPEWORMS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Referring to the recent article by Dr. Chamberlin,[1] in which he makes the statement that tapeworm disease seems to be almost entirely confined to womankind, and to the later communication by Dr. Dowling,[2] in which he cites cases in men, I have thought that the following statistics upon the subject would not be uninteresting to the readers of the MEDICAL RECORD:

CASES OF TAPEWORM IN MAN.

Total Number of Cases Reported.	Sex of Patients. Female.	Male.	Authority.
173	117	56	Wawruch.
247	151	96	Crisp.
26	16	10	Seeger.
240[3]	129	111	Monti.
10[3]	7	3	Roger.
367	241	126	Krabbe.
1,063	661	402	

It will be seen from these statistics that about sixty-two per cent. of the cases reported by the six authors cited were among women, and about thirty-eight per cent. among men.

A moment's thought will, I believe, make the reason of this difference clear to us. We certainly cannot assume that women are from sex predisposed to tapeworm infection, but we should recall that they are more exposed to such infection from the fact that they, more than men, prepare food for the table.

I am not familiar with the statistics which Dr. Chamberlin cites from the French army, namely, one case of tapeworm disease in every 36,000 men, but find it extremely difficult to accept the proportion given. Bérenger-Féraud[4] gives the following figures for the maritime hospitals in France, but does not state the sex of the patients:

CASES OF TAPEWORM IN MAN IN MARITIME HOSPITALS OF FRANCE—1861 TO 1890.

1861 to 1865	33	cases in	130,927	patients, or	0.20	per 1,000
1866 " 1870	95	" "	152,822	" "	0.62	" 1,000
1871 " 1875	422	" "	137,361	" "	3.06	" 1,000
1876 " 1880	1,108	" "	130,898	" "	8.45	" 1,000
1881 " 1885	1,505	" "	155,646	" "	10.05	" 1,000
1886 " 1890	2,253	" "	152,352	" "	14.80	" 1,000

The statistics for our own country are very incomplete, but I have shown elsewhere[5] that on the Federal side during our late war, "in a total of 5,548,854 patients from July 1, 1862, to June 30, 1866, only 566 were diagnosed as having tapeworms, or 1 in 9,803."

Unfortunately our American statistics have not taken the various species of tapeworm into account, but so far as I can judge from the specimens which physicians and others have sent to this bureau for determination from various parts of the country, Tænia saginata, the beef-measle tapeworm, is by far the most common form with us; Tænia solium, the pork-measle tapeworm, is much less common. I have seen only three cases of Bothriocephalus latus in the United States, and only one case of Hymenolepis diminuta (Tænia flavopunctata). No cases in man of Hymenolepis murina (Tænia nana,) Dipylidium caninum, Davainea Madagascariensis, Bothriocephalus cordatus, Bothriocephalus Mansoni, or Krabbea grandis have as yet been sent to us.

As for Ward's new species (Tænia confusa), his original specimen is the only material of this kind I have examined. This worm, which presents most remarkable segments, will soon be described in detail by one of Ward's pupils, and until this publication appears it will be lost time to discuss the form. Suffice it to say that physicians should be on the lookout for a tapeworm with enormously long (twenty-seven to thirty-five millimetres) segments, and should send the specimen, if found, either to Prof. Henry B. Ward, University of Nebraska, Lincoln, Neb., or to me, or to some other helminthologist for zoölogical determination. I am particularly anxious to obtain a complete specimen with head, for I feel convinced that the head which Ward has described does not belong to the body he studied, but to a specimen of Dipylidium caninum—a view which has already occurred to Ward.

In connection with the question of treatment which Dr. Chamberlin discusses, I take the liberty of adding three suggestions which may be of service to your readers. Two of these suggestions are based upon the natural habits of the tapeworm.

It is generally assumed that a tapeworm is a low kind of animal without nerves. On the contrary, he has a very complicated nervous system which demands that we must treat him with a certain amount of respect. In the head the tapeworm possesses well-developed ganglia, and running from these are two enormous lateral nerves which extend through the entire worm, giving off branches to every segment. An insult to the end segment will thus be communicated to the head. Now, it is a frequently observed phenomenon that if a tapeworm, more particularly a delicate species, is suddenly thrown into cold water, it will often break into several pieces. It is also a frequently observed fact among physicians that when a patient is passing a tapeworm the parasite will suddenly break in two. A moment's reflection will show that the tapeworm in this latter case is passing from the warm bowels to the cold air, perhaps into a cold porcelain vessel. To fool the parasite, care should be taken to prevent this sudden change of temperature. This can be very easily done. The patient should be instructed to use a vessel containing warm water.

Again, tapeworms have a habit of "tying themselves up into a knot," with the head in the centre, and they are frequently expelled in this form. If, however, they meet with any obstruction in the lower bowels, they have an opportunity of extricating their heads and thus of gaining hold of the walls of the intestine. The clearing out of the lower bowels is therefore all-important in treating for tapeworms.

Finally, it is essential that the mixture used for treatment should not be so old that it has lost all its anthelmintic properties.

Disregard of the three details in treatment here suggested will account, I believe, for the majority of the failures in treating for tapeworms.

Dr. Chamberlin well remarks that the symptoms of tapeworm disease are not well defined. If we take all the symptoms ever described for all diseases, shake them up in a hat, and pick out any combination of them at random, we obtain a clinical history of tapeworm disease. In experimenting upon myself with tapeworm infection (Tænia saginata was the species used), the most constant symptom I have noticed is one which I have never seen directly mentioned in any article. During the time of infection, it would very frequently happen as I walked along the street or across the room that I suddenly felt a peculiar sensation almost exactly similar to the sensation one feels upon the sudden descent of an elevator.

Notwithstanding the indefinite clinical picture (its indefiniteness almost makes it definite), I can see no

earthly excuse for diagnosing tapeworm when no tapeworm is present. At the first suspicion of tapeworm a microscopic examination of the fæces should be made. If tapeworms are present and large enough to cause any trouble, they will also be large enough to fill the fæces with their characteristic eggs. If no eggs are found in this examination, we can conclude either that there are no tapeworms present, or that if present they are too young to cause any serious trouble. It is indeed to be regretted that the microscopic examination of the fæces is not so general as that of the urine.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 16, 1897:

	Cases.	Deaths.
Tuberculosis	205	101
Typhoid fever	44	7
Scarlet fever	115	7
Cerebro-spinal meningitis	0	4
Measles	85	5
Diphtheria	127	15
Laryngeal diphtheria (croup)	4	1
Chicken-pox	8	0

Medical Men in Germany.—Statistics recently published show that the proportion of medical men to population in the leading towns of the German empire is as follows: In Charlottenberg the ratio is 1 doctor to every 624 inhabitants; in Halle-on-Saak, 1 to 684; in Munich, 1 to 778; in Frankfort-on-the-Main, 1 to 785; in Königsberg, 1 to 792; in Berlin, 1 to 807; in Stuttgart, 1 to 810; in Breslau, 1 to 834; in Dresden, 1 to 943; in Hanover, 1 to 974; in Stettin, 1 to 1,042; in Danzig, 1 to 1,064; in Leipzig, 1 to 1,082; in Aachen, 1 to 1,162; in Brunswick, 1 to 1,203; in Dusseldorf, 1 to 1,227; in Cologne, 1 to 1,250; in Hamburg, 1 to 1,284; in Nuremberg, 1 to 1,336; in Magdeburg, 1 to 1,339; in Bremen, 1 to 1,364; in Dortmund, 1 to 1,556; in Altona, 1 to 1,752; in Elberfeld, 1 to 1,960; in Chemnitz, 1 to 1,987; in Barmen, 1 to 2,082, and in Crefeld, 1 to 2,145.—*British Medical Journal.*

Nightsoil and Ashes for Manure.—Experiments made by the farm committee of the town council of Crewe in the direction of mixing crude nightsoil with fine ashes and sulphuric acid proved so successful in 1895 that last year covered mixing sheds and screens were erected for that purpose. The dry ashes are thrown on the screen by hand. The screen is a two-decker, and as it moves the broken crockery, glass, tins, etc., are thrown off to the top screen, whence they are removed and used in road-making. The lower screen catches the combustible matter (chiefly cinders), which is put in the stokehole and used to raise the steam. There is left only the fine ash under the screen, which is wheeled to another part of the shed and spread on iron plates covering the flue leading from a small furnace to the boiler chimney. This small furnace is used for the combustion of paper and large articles which could not conveniently be put in the stokehole, and supplies heat to the flue over which the fine ashes are spread. When the ashes are fairly dry, they are sprinkled with commercial sulphuric acid to the extent of about four per cent. by weight. After a few days the acidulated ashes are wheeled into the mixing-shed and thrown on the top of the crude night-soil, which has been tipped there during the previous night. From an analysis which has been made the manure is found to contain twenty-six per cent. of organic matter.

A Propos of the recent French barber-shop sanitation, the following clipping from the *Medical Press* is of interest: "A proprietor of a barber's shop has very justly been fined £5 and costs for attending to his business while still passing through the peeling-stage of scarlet fever."

Toads.—The ancient belief that the toad was a venomous animal has been lately shown to be not altogether without foundation. The cutaneous glands of the toad do secrete a venom which is in a high degree toxic when introduced into the circulation. The production of venom is by no means confined to the common toad and land salamander, but is met with in allied species, the natterjack and tropical toads, and to a small extent the frogs. The creatures are unable voluntarily to eject the venom, which is secreted only in response to some reflex irritation and has a purely defensive function.—*Science Progress.*

Nitroglycerin in Children.—Dr. Angel Money states in *The Lancet* that nitroglycerin appears to have no toxic effects in infants and small children even in very large doses. He constantly prescribes one minim of a one-per-cent. solution to infants under the age of two years every two or three hours in place of sweet spirits of nitre.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended October 16, 1897:

ANTISEPTICS IN EYE SURGERY.[1]

BY HENRY D. NOYES, M.D.,

NEW YORK.

FOR operations on the eye, meaning especially extraction of cataract, experience has shown that the usual antiseptic methods of surgery must be modified in several particulars. I can best set forth my own practice and the practice of my colleagues of the New York Eye and Ear Infirmary, under the heads of, first, the operator; second, the instruments; third, the field of operation; fourth, the dressings.

1st. As a rule the surgeon puts on a clean white sack, either over or in place of his ordinary coat. His hands are carefully scrubbed with soap and water, and powdered borax is freely sprinkled on the brush. Special attention is given to the nails, and the borax has a potent effect in getting rid of grease and dirt. After the scrubbing, immersion in a sublimate solution, 1 to 3,000, leaves the hands sufficiently purified for an operation when the fingers do not come in contact with the field, and with the sense of touch unimpaired. The operator will not have need to touch any other part than the lids, and all other contacts are by instruments.

2d. All instruments, except knives and needles, are put in boiling distilled water for about ten minutes, then laid in ninety-five-per-cent. alcohol for ten minutes, and transferred to a clean and sterilized porcelain tray and covered by a towel wet in sublimate solution, 1 to 1,000. The alcohol is used for this purpose only once. Knives and needles are simply plunged for a minute in boiling water and then laid in alcohol with the other instruments. All are very carefully wiped with muslin or cotton wet in alcohol. Sometimes at the last moment a knife or curette or probe may be dipped in a bottle of alcohol and smartly shaken to throw off excess of fluid. If made of platinum, a probe or spatula may be passed through an alcohol flame. Rubbing carefully will cleanse smooth and straight instruments. Forceps, scissors, and speculum, and all instruments having joints and holes are subjected to rigorous treatment before and after an operation. They must be perfectly clean when put away and will then be ready for sterilization when next required. They are stored in metal racks on glass shelves within a tight cabinet.

3d. The patient has a warm bath, and is to be attired in clean clothes for lying in bed. Should there be manifest irritation of the lids or of the conjunctiva, suitable treatment is adopted until a safe condition is attained. It is the habit of some surgeons to bandage the eye for twenty-four hours in order to detect chronic conjunctivitis, and not to operate so long as any secretion exists. The majority of surgeons, and I include myself, are satisfied with inspection to discover the condition of the parts, and regard bandaging as giving occasion to secretion, and so far tending to create what we wish to avoid. A moderate degree of chronic conjunctivitis is common to old persons, and if the secretion is mucoidal and not copious it does not forbid an operation, neither will treatment wholly remove it. Chronic inflammation of the lid borders and ectropion demand effective treatment. Chronic dacryo-cystitis, as is well known, constitutes a serious danger. There is usually no time for ordinary treatment, and the destruction of the sac by cautery or its removal by dissection is doubtless the wisest proceeding, and will demand at least two or three weeks before extraction can be ventured. We do not fail to realize the dangers of the complication when the lacrymal disease is clearly manifest, but I speak from a sad experience when I remember that suppuration may attack the cornea several days after the operation, as the result of dacryo-cystitis which had for years been in abeyance, but was lighted to fresh activity by the reaction of a perfectly normal cataract extraction. One must therefore not be satisfied by negative objective evidence as to lacrymal disease, but also remember to inquire into past history on this point. Bad nasal catarrh has also a dangerous character and might be inhibitory until sufficiently mitigated by treatment. Pterygion as an evidence and complication of chronic conjunctivitis may demand removal and subsequent treatment until no serious irritation remains. It is well known that germs are found in great numbers under the edges of a pterygion, and their hiding-places must be abolished. Supposing the case free from or relieved of the complications specified, and the patient in bed, the parts about the eye are scrubbed with soap and water, special attention being given to the eyebrows, and rinsed off with a sublimate solution, 1 to 3,000. The edges of the lids are carefully wiped with a pledget of cotton dipped in boric-acid solution.

Towels wrung out of sublimate, 1 to 1,000, are wrapped around the head and under the chin. The lids being separated by the speculum, the conjunctival sac is thoroughly flushed with a two-per-cent. solution of boric acid or the physiological salt solution. The stream from the rubber bulb is directed especially into the culs-de-sac above and below, into the semilunar fold, and into the outer angle. Shreds of secretion may be caught by the speculum, and great pains must be taken to remove all such material. By this proceeding all coarse flocculi are removed, and this is all that can safely be attempted. Sublimate solution, 1 to 10,000, is equally admissible and has a coagulating property greater than the above solutions, but in no case is any fluid of an irritating character employed. It is well known that micro-organisms are always present on the normal conjunctiva, and washing cannot remove them, but it does carry away shreds and flocculi in which doubtless plenty of germs are contained. What proportions are harmless and what are pathogenic we cannot know. But all strong antiseptics cause irritation and unfavorably influence the healing process. Perhaps, as Randolph has suggested, this is explained by conversion of harmless germs into others of a pathogenic quality. The anæsthetic solutions of cocaine or any other drug, and in my practice atropine solution, four grains to the ounce, which have

[1] Read in the section of ophthalmology at the meeting of the British Medical Association in Montreal, September 1, 1897.

already been employed, are absolutely sterile and furnished fresh for each operation in half-drachm bottles, corked and sealed, and not used again unless sterilized anew.

At the close of the operation I frequently let the stream from the bulb play forcibly on the wound to wash away clots and débris, and it often forces its way into the anterior chamber. I may gently press open the wound and often succeed in expelling material.

I have given up the practice of irrigating the anterior chamber by a pipette or instrument entered within it. Panas' fluid, the biniodide of mercury, 1 to 20,000, injected into the chamber, I have seen in several instances to bring about patchy opacity of Descemet's membrane, and I have ceased to use it. In flushing the eye, whether before or after the section, the speculum may be lifted from the globe to give the fluid freer access. If, as is usual with me, the speculum has been removed before the lens is delivered, the upper lid is held by a strabismus hook and the lower lid by the finger of an assistant. It is none the less easy to wash off the eyeball.

If prolapse of the vitreous has occurred, the greatest care should be used to excise all that may intrude between the lips of the wound, because it is a most fertile medium of infection. This remark applies to the normal and not to fluid vitreous.

4th. Dressings. The absorbent cotton, the bandage whether of gauze or flannel, the muslin patches, have been kept in an oven for two hours at a temperature of about 300° F., inclosed in a perforated tin box and then are placed in a covered glass jar and are exposed to the air only at the moment when called for. No antiseptic substances are employed to medicate them —reliance is placed upon the efficacy of dry heat and careful seclusion and frequent renewal. If a bandage is to be used, the muslin patch is dipped in sublimate, 1 to 3,000; the dry cotton, as it lies upon the eye before the bandage is applied, is wetted with the same solution. The moist dressing is a comfort to the patient and facilitates escape of fluid from the lids. It is my habit to remove and renew the dressing every twenty-four hours, and under the same precautions. I always assure myself whether a normal process of healing is taking place, and if any sign of infection appears I am prepared immediately to institute treatment. I may remark that the continuous use of water as hot as can be borne, about 110° to 115° F., with cotton compresses, is the effective treatment to stay the progress of suppuration. If there be exudation in the anterior chamber, I usually remove it and may also attempt irrigation by sublimate, 1 to 3,000. I have seldom used the actual cautery or pure carbolic acid on the wound, and in most cases the degree of reaction forbids much interference beyond the use of hot fomentations.

Within five years in my private practice two cases have occurred in houses where at the time of operating I have discovered that there was a foul water-closet in the vicinity of the patient's room. I adopted all available precautions to prevent mischief in the details above narrated, and ventilated the rooms thoroughly before operation, yet suppuration attacked the wounds. One eye escaped unharmed. The eye of the other patient was badly damaged. In such cases the pernicious germs must be in the air in too great numbers to be dispelled or neutralized, and the lesson is to refuse to operate in places of such unsanitary surroundings. Whatever exceptions may seem to invalidate the rule, it is certainly the wisest and most salutary for the patient to restrict operations to properly constructed and properly administered hospitals. It is evident that in eye surgery we are limited in great degree to measures of asepsis rather than of antisepsis, and that our attention must be given chiefly to the purity of the hands and especially of the instruments, the solutions, and the dressings.

THE PRECIPITATION OF EARTHY PHOSPHATES FROM URINE BY HEAT.

By J. B. NICHOLS, M.D.,

THE frequent appearance of a cloudiness or precipitate upon boiling urine, clearing with the addition of acid, is a phenomenon familiar to those who have had the least experience in the examination of this fluid. Some explanations have been offered as to the cause of the precipitation, most of them in a measure true, but no one of them adequate alone to account for all the phenomena which present themselves. The subject is usually mentioned very briefly and imperfectly in the standard works on the urine, and it seems generally to be little understood. It is the purpose of this paper to present the results of a study of this point.

The phenomena present in the ordinary manipulations of urine are these: On being heated in a test tube, as in testing for albumin, to a point at or near the boiling temperature, a white cloudiness or precipitate appears in some (not all) specimens of urine, which clears up when a drop or two of acid is added —a reaction which distinguishes phosphates from an albuminous precipitate. If the urine be cooled again after the cloudiness has been developed by boiling, the precipitate is totally or partially redissolved, and the fluid clears either entirely or in part.

Composition of the Precipitate.—The precipitate thus thrown down by heat consists of phosphates of calcium and magnesium. Some observers have asserted that calcium carbonate, calcium sulphate, calcium oxalate, and a proteid compound also occur in the precipitate (Sommer and Scharling, Stokvis, Méhu), while by others the presence of magnesium phosphate has been denied and ignored. In a couple of analyses made by me, the precipitate being very profuse, I found the phosphates of both calcium and magnesium present, while carbonates and sulphates were absent. The magnesium phosphates being more soluble than those of calcium, it is probable that the calcium salt might be present alone in cases in which only a slight precipitate is produced by heat; the carbonate, sulphate, and oxalate of calcium are probably precipitated in boiling urine only exceptionally, if ever, while proteid substances would be absent in non-albuminous urine.

The "earthy phosphates" which occur in the urine are the orthophosphates of calcium and magnesium. These phosphates are as follows:

$CaH_4(PO_4)_2$, variously called tetrahydro-calcic phosphate, acid calcium phosphate, dibasic calcium phosphate, monocalcic phosphate.

$CaHPO_4$, monohydro-calcic phosphate, monobasic calcium phosphate, dicalcic phosphate, neutral calcium phosphate.

$Ca_3(PO_4)_2$, tricalcic phosphate, normal calcium phosphate: it is also frequently called basic calcium phosphate, though, it would seem, from the strict meaning of the term, inaccurately.

$MgH_4(PO_4)_2$, tetrahydro-magnesic phosphate, monomagnesic phosphate, acid or dibasic magnesium phosphate.

$MgHPO_4$, monohydro-magnesic phosphate, dimagnesic phosphate, neutral or monobasic magnesium phosphate.

$Mg_3(PO_4)_2$, trimagnesic phosphate, normal or "basic" magnesium phosphate.

These phosphates are readily transformed from one to another by changes in the surrounding conditions; they exist in the urine in rather indefinite proportions, varying according to circumstances. In general, they are only slightly soluble in pure water, the normal salts being least and the dibasic salts most soluble; the magnesium phosphates are somewhat more soluble than the calcium phosphates. They are quite soluble in acid fluids, even if only slightly acid. Certain neutral salts, as sodium chloride, also have considerable solvent power over the earthy phosphates. Their solution in the urine is believed to be chiefly due to the presence of acid salts, especially acid sodium phosphate, NaH_2PO_4, to which the acidity of the urine is generally mainly attributed, also to CO_2, NaCl, etc. The earthy phosphates are insoluble in alkaline media, and hence are precipitated from the urine upon the addition of alkalies.

Cause of the Precipitation.—Numerous explanations have been offered as to the cause of the precipitation of the earthy phosphates from urine by heat.

1. The appearance of the precipitate when urine is heated and its re-solution on cooling readily suggest the hypothesis that the earthy phosphates are less soluble in hot than in cold media. This explanation is offered by Dalton, Roberts, Kober, Fowler, and Woody, and, partially, by Jones. It is perhaps a superficial conclusion and not based on critical investigations (which in this case, indeed, present peculiar difficulties); yet in the various discussions of the subject which I have found I have never seen this view specifically denied or questioned. It is certainly very unusual for the solubility of solids to decrease with heat, but such cases, as that of calcium hydrate, occur. While this factor may possibly be operative, and perhaps in high degree, the occasional failure of the precipitate entirely to redissolve on cooling shows, however, that it can not be the sole element involved in the case of the urine.

2. One of the chief explanations of the precipitation of the phosphates by heat is based on the supposition that the chemical nature of the phosphates varies with changes of temperature, less soluble salts being formed by heat. This theory, which is generally attributed to Scherer, has been held or concurred in by Carles, Huppert, Jones, Ott, Parkes, Schaffner, Smith, Stokvis, Van Nüys, and Wynkoop, and quoted by numerous others.

According to Huppert's revision of Neubauer and Vogel's work on urine analysis, which apparently presents the best chemical knowledge of the subject, the solubilities of the earthy phosphates and the changes effected in them by heat are as follows: $CaH_4(PO_4)_2$ is soluble in about 700 parts of pure cold water; $CaHPO_4$ in about 6,700 parts; $Ca_3(PO_4)_2$ in about 100,000 parts. $MgH_4(PO_4)_2$ is quite soluble in water; $MgHPO_4$ (anhydrous) in about 1,000 parts of cold water; $Mg_3(PO_4)_2$ (the freshly precipitated amorphous salt) in about 5,000 parts. Their solubilities are increased in the urine by the presence of acid and neutral salts, which also retard the changes brought about by heat. Dibasic phosphate, if in sufficiently concentrated solution, on being heated, partially breaks up into phosphoric acid and monobasic phosphate, thus:

$$CaH_4(PO_4)_2 = H_3PO_4 + CaHPO_4.$$

The monobasic salt being much less soluble remains partially undissolved. Owing to the insufficient concentration of the solution of $CaH_4(PO_4)_2$ this reaction is not supposed to take place in the urine. On heating sufficiently concentrated solutions of the monobasic salts, they partially break up into the dibasic phosphates, which remain in solution, and the normal phosphates, which being only slightly soluble are partially precipitated, thus:

$$3(CaHPO_4) = CaH_4(PO_4)_2 + Ca_3(PO_4)_2.$$
$$3(MgHPO_4) = MgH_4(PO_4)_2 + Mg_3(PO_4)_2.$$

The chemical theory of Scherer and others, then, is this: On heating urine, if the earthy phosphates are in sufficiently concentrated solution, the monobasic salts partially break up into the insoluble normal phosphates, which precipitate, and the soluble dibasic phosphates. On cooling, the reverse process is supposed to take place and the precipitate wholly or partially disappears. Under the conditions present in the urine the occurrence of any changes in the dibasic phosphates is disregarded.

According to this theory, accompanying the formation and precipitation of normal phosphates there should be an increase in the acidity of the solution due to the increased quantity of the acid dibasic phosphates formed. That boiling increases the acidity of urine which precipitates phosphates on heating has been asserted by some observers, and this is confirmatory of the hypothesis under consideration. Other observers have not found this increase of acidity; and Brett asserted that it is apparent rather than real, and is due to a more marked action of fluids upon litmus paper while hot. My own experiments have been too few to warrant any definite conclusion as to the relative acidity of such urine while hot; still, I have not been able to find any increase in the acidity over what it was before boiling. I have constantly found boiled urine after cooling to be materially diminished in acidity. It is worthy of notice that an increase of acidity would probably promote the solution of the normal phosphates formed.

By adding to a solution of $CaCl_2$ or of $MgSO_4$ one of Na_2HPO_4 (not in excess), and filtering away the precipitates, clear solutions free from CO_2 will be obtained, containing phosphates of calcium and magnesium respectively, which, on boiling, will give precipitates that will clear partially but not wholly on cooling. This result may in the case of fresh solutions be partly due to a more active reaction between the sodium phosphate and the calcium and magnesium salts taking place under the influence of heat, resulting in an increased production of calcium and magnesium phosphates; but aside from this it cannot be explained on any other theory yet offered than that of a chemical change in the earthy phosphates being effected by heat. This theory is, therefore, at least in part, probably true with respect to the occurence of the phenomenon in urine. That it is the chief, or even a prominent, factor in the case cannot, I believe, be affirmed until it is shown that these phosphates are not absolutely less soluble in hot than in cold fluids.

3. It has occurred to me that the supposition (hinted at in the preceding paragraph) might be entertained that under the influence of heat a more vigorous reaction might occur between the sodium and potassium phosphates and calcium and magnesium salts other than phosphates in solution in the urine, resulting in an increased formation of the earthy phosphates. This supposition may be dismissed with the remark that these phosphates may be precipitated by heat from artificial solutions in which no other phosphates are present, and that in the urine calcium and magnesium do not normally occur to any extent except as phosphates.

4. Salkowski about 1883 presented the theory that calcium phosphate occurs in the urine in a weak combination with sodium or potassium phosphate, which is broken up by heat, causing the calcium phosphate to separate and precipitate. No other authority appears to have accepted this view, and it has been combated

by Smith. As the precipitation by heat may occur in artificial solutions in which no sodium or potassium salts are present, this theory may be dismissed from consideration.

5. After prolonged heating the precipitate, or its persistence after cooling, may be partially due to loss of fluid by evaporation. This, however, cannot account for the precipitation as it occurs in the ordinary brief boiling in a test tube.

6. An explanation of the phenomenon in question which has gained considerable currency is that the earthy phosphates are, partially at least, held in solution in the urine by free carbon dioxide, CO_2, and that upon its expulsion by heat they are precipitated. This theory was first presented by Brett, in 1836; it has been held also by Heller, Landois, Loebisch, Neubauer, Salkowski and Leube, Tyson, Ultzmann and Hofmann, Vogel and Zülzer.

Carbon dioxide dissolved in water gives it a degree of acidity, due to the presence of virtual carbonic acid, H_2CO_3. The gas is expelled from watery solution by heating; it may also be driven out with some facility, without heat, by vigorous agitation. The earthy phosphates of the urine are soluble in water containing CO_2, as in other acid media; and a permanent precipitate is obtainable in such solutions on dissipating the gas either by heating or, to a less extent, by vigorous agitation. Free CO_2 is a normal ingredient of urine; and the natural inference follows that it has some solvent influence over the earthy phosphates there and that its expulsion by heat or otherwise would tend toward their permanent precipitation.

The acidity of urine is usually (after the fluid has cooled, at least) materially and markedly diminished by boiling. This fact, pointed out by Brett in 1836, I have verified by repeated trials, determining the acidities by titration with decinormal sodium hydrate solution, phenolphthalein being used as the indicator; the color of urine interferes somewhat with a close estimation of the point of neutralization when phenolphthalein is used, but the results were sufficiently accurate for comparative purposes. Within certain limits it appears that the longer the heat is applied the greater is the decrease of acidity and the more profuse is the precipitation. I have also been able to effect a slight diminution of the acidity of urine by vigorously shaking it, though I have never produced a precipitate in this way.

It is probable that the decrease of acidity of urine caused by heating is due to the expulsion of CO_2. From *a-priori* considerations precisely that result is to be expected from the presence of CO_2 in the urine; reasoning by exclusion there is no other acid principle in the urine upon which heat is capable of producing so marked and rapid an effect; and the behavior of urine in this respect corresponds closely with that of solutions of CO_2.

The expulsion of CO_2 and the diminution of acidity caused by heating urine, with the resultant decrease of solvent power over the earthy phosphates, readily suggest themselves as a cause of the precipitation of the latter. Moreover, I have found the precipitate produced by boiling when the urine is fresh (CO_2 being then present) to be more profuse than on subsequent boiling (when CO_2 is absent) after the first precipitate is filtered out. The re-solution of the precipitate on cooling, and the fact that turbidity can be produced by heat in solutions of the phosphates free from CO_2, on the contrary, show that the expulsion of this gas is not the chief cause of the precipitation; but it must have some action in the case, especially, perhaps, in the instances in which the precipitate does not entirely redissolve on cooling.

A cursory investigation was made to determine whether the expulsion of CO_2 might not account for the occasional precipitation, by heat, of the carbonate, sulphate, and oxalate of calcium reported by some observers. Calcium carbonate is somewhat soluble in water containing CO_2, and is precipitated by heating; but I could produce no similar result with the sulphate or oxalate. Calcium carbonate is also precipitated on boiling solutions of calcium bicarbonate or calcium carbamate, which may under certain unusual circumstances occur in urine.

7. The transformation of urea to ammonium carbonate by heat is an old explanation, attributed to Henry, of the precipitation of the earthy phosphates, and has recently again been presented by Shattock. The re-solution of the precipitate on cooling is fatal to this theory; also the fact that the precipitation may occur in solutions free from urea. Heat, it is true, slowly decomposes urea, and if the ammonium carbonate produced remained in the urine the effect would be a decrease of acidity; but the heat that acts on the urea also drives out the NH_3 and CO_2, and it is hardly conceivable that under ordinary circumstances ammonium carbonate could remain in the fluid. The precipitation after prolonged boiling, cited by Shattock in favor of his theory, is probably due to evaporation of the fluid.

8. The theory that the earthy phosphates are held in solution in urine by ammonium chloride, whose decomposition by heat causes them to be precipitated, was presented by Rees and Barlow in 1836, but has received no support. This hypothesis may possibly be correct enough in a degree so far as artificial solutions are concerned, but it can have little share in the explanation of the phenomenon as it occurs in the urine, for the following reasons: The clearing of the precipitate on cooling alone overthrows it. Ammonium chloride occurs in normal urine only in minute proportion, and its solvent influence on the earthy phosphates is insignificant in comparison with that of sodium chloride and the acid salts of the urine. The earthy phosphates give a precipitate on heating also when dissolved in an aqueous solution of sodium chloride, which is certainly not dissipated by boiling; and the same precipitate is obtainable in numerous other artificial solutions containing no ammonium chloride. Rees stated that the acidity of urine is increased by boiling, and accounted for it by loss of ammonia.

Among the experiments made by me the following may be cited for its general bearing on the subject: A quantity of earthy phosphates was obtained by adding sodium hydrate to urine, and filtering, washing, and drying the precipitate at room temperature. A saturated solution of these phosphates was made in water containing CO_2; on boiling in a test tube a profuse precipitate was obtained, clearing somewhat but still marked on cooling, and about half the CO_2, as determined by volumetric acidimetry, was expelled; after vigorously shaking in a test tube a slight precipitate was obtained, the CO_2 being decreased one-half. A saturated solution of the phosphates was made in a solution of NaH_2PO_4 of a strength about equal to that of the urine; on boiling in a test tube a profuse precipitate appeared, which on cooling was nearly or entirely redissolved, the acidity of the solution not being diminished; on dilution with about double the amount of the NaH_2PO_4 solution no precipitate occurred on heating. A solution of the phosphates was made in the above-noted solution of NaH_2PO_4 to which CO_2 had been added; on boiling a profuse precipitate was formed, which cleared only partially on cooling, most of the CO_2 being expelled; no precipitate could be obtained by brisk agitation, although CO_2 was driven out to the same extent as by boiling. A saturated solution of the phosphates in one-per-cent. solution of NaCl gave a slight precipitate on

boiling, clearing when cool. It thus appears that the precipitate forms on heating whether CO_2 is present or not; but when it is present the precipitate is more persistent on cooling. The expulsion of CO_2 by shaking has much less effect in producing the precipitate than has heating.

From all the considerations above presented the following conclusions seem justified: The precipitation of the earthy phosphates from urine by heat is mainly due either (*a*) to their chemical nature being altered by heat, less soluble salts being formed, while the process is reversed on cooling and the salts redissolve; or (*b*) to their being less soluble in hot than in cold media and being therefore thrown down by heat, redissolving on cooling. Possibly both these factors are operative, and the former one certainly is to some degree. Another cause, which is perhaps especially manifest in those cases in which the turbidity persists after cooling, is the expulsion of CO_2 and loss of acidity caused by heating, which diminish the solvent power of the urine over the earthy phosphates. After prolonged boiling the precipitate or its persistence on cooling may be also partially attributed to evaporation of a portion of the fluid.

This statement does not entirely clear up the obscurity of the subject, but it defines the sphere of operation of certain factors and limits the field within which the true main cause of the precipitation is to be found.

Circumstances under which Precipitation Occurs.—The occurrence of the precipitate depends upon the degree of concentration of the earthy phosphates in solution in the urine; turbidity will be produced by heating only when the concentration is so great that when the fluid is heated the point of saturation is passed. This explains why the phenomenon does not occur with all specimens of urine. If in relatively strong solution, the phosphates will be profusely precipitated by heat, and (especially in connection with the lessened acidity caused by boiling) the precipitate will not entirely clear on cooling; in a less degree of concentration the fluid will become turbid on boiling and entirely clear again after cooling; while in relatively weak solution there will be no precipitate whatever on heating. This view is confirmed by the fact that upon cautiously adding alkali to urine that gives no precipitate on boiling, thus increasing the relative concentration of the phosphatic solution by diminishing the acidity, a point can be reached where the fluid will become cloudy on heating and clear again when cool; and by carrying the process still further a precipitate which persists on cooling can be obtained with heat. A similar result can be obtained by adding calcium chloride, which increases the amount of calcium phosphates present and so augments the phosphatic concentration.

It is to be observed that the concentration of the solution of phosphates in the urine depends upon two distinct factors: (*a*) the absolute quantity of earthy phosphates present, and (*b*) the amount of the substances (acid phosphates, CO_2, chlorides, etc.) which hold the earthy phosphates in solution. Hence the occurrence of the precipitate on heating urine has in itself no significance as to the quantity of earthy phosphates present; it indicates simply their relative concentration in the fluid, and may be due either to excess of phosphates with high acidity of the urine, or, as is usually the case, to low acidity with a smaller amount of phosphates. It is to a slight degree susceptible of a positive or corroborative interpretation, taken in connection with a known high acidity as to the quantity of earthy phosphates, or in the presence of a sediment as to its phosphatic nature. The phenomenon occurs alike in urine from healthy and diseased persons, and has little or no clinical significance.

Literature.—I have been unable to find the original writings of Henry, Scherer, Schaffner, Sommer and Scharling, and Beneke, who have made studies of this subject. Aside from numerous works which make only a bare mention of the phenomenon, the following list exhibits the literature bearing on the subject which I have found:

THE DIFFERENTIAL DIAGNOSIS BETWEEN MALARIAL AND TYPHOID FEVERS.[1]

By J. F. JENKINS, M.D.,

JACKSON, MICH.

THE difficulties in making a diagnosis between malarial and typhoid fever are in many instances very great, from the fact that typhoid fever presents itself under so many and varied conditions, the type at one time being very marked, at another time assuming many of the phases of malarial fever. Sporadic cases occurring in country districts and very generally in villages are not infrequently diagnosed malarial fever, and doubtless the deaths reported to local boards of health under the head of malarial fever are usually due to typhoid fever.

Dr. Osler states in a paper recently read by him that "north of Mason and Dixon's line physicians are prone to diagnose malaria for other disease; south of the line they are more prone to diagnose other disease for malaria; in both regions it is a source of greater error than any other affection." There are many localities in this State, as well as other States north of Mason and Dixon's line, where malarial fever still prevails, especially during the autumnal months, and it is in these sections that it is so frequently found a difficult question to determine whether the patient has malarial or typhoid fever.

In each and every case the source of infection should be thoroughly investigated, and in many instances such an investigation will give material aid in arriving at a correct diagnosis.

It is seldom that typhoid fever commences with a pronounced chill, while malarial fever is usually ushered in with a chill, more or less severe, followed by high fever; sometimes typhoid fever commences with a distinct chill—that is, with a shaking chill; but the temperature rise is not so abrupt, never reaching 103° to 105° F., as it usually does in malarial fever within the first twenty-four or forty-eight hours. The development of typhoid fever is in the large majority of cases slow and insidious; there are a feeling of weariness, general malaise, some fever, which increases day by day, and under these conditions quinine may be administered in antiperiodic doses and may lessen the pyrexia, but, like the annual overflow of the Nile, it is certain again to make its appearance. In malaria epistaxis is rare, while in typhoid fever in its incipient stage it is frequently present, especially among the young, but seldom occurring in patients beyond the age of fifty. In malarial fever the pulse rate will not be very much increased by taking the patient suddenly from bed and placing him in the upright position, while in the incipient stage of enteric fever the pulse rate is greatly increased by such a change of position. In the early stage of typhoid fever this alteration of position will frequently assist in determining the nature of the fever.

Where the malarial fever prevails, and it is a question whether or not the infection is the product of the Eberth's bacillus or the hæmatazoa of malaria, ten grains of quinine given every three or four hours until thirty grains are administered, and this amount repeated every twenty-four hoursf or two or three days, will materially assist in differentiating the disease. The infection of malaria will be destroyed by quinine, while in typhoid fever the drug may reduce the pyrexia, but it will soon reappear. Among the lagoons of Northern Indiana, more than a quarter of a century ago, the writer followed out a plan similar to the one above mentioned, and frequently found that instead of malarial infection the only factor in the case was the infection of typhoid fever. These fevers commonly had all the characteristics of typhoid fever, excepting that they were invariably accompanied by profuse perspiration. The local physicians termed them "slow fevers," and finally they assumed the name of typho-malarial fevers, but post-mortem examinations whenever made disclosed the pathological lesions of typhoid fever.

The importance of making an early diagnosis in typhoid fever is generally admitted, because the hygienic and dietetic management of the disease is absolutely of more importance than internal medication; the lesion in the alimentary canal often leading to fatal results, even in apparently the mildest form of enteric fever.

Within the past few years the microscope has made us familiar with the typhoid bacillus, and bacteriologists have mde us acquainted with its natural history, its growth, its favorite habitat for development, how it behaves within and without the body, its most favorable conditions for propagation, and how to avoid and destroy the bacilli outside the body. These facts are still leading us to more certain methods of diagnosis, and we may look forward to methods which will be more definite in making out a differential diagnosis of fevers instead of depending upon symptoms.

Ehrlich's test, or what is termed the diazo-reaction, appears to have a limited value. This test, which it is not necessary to describe here, typhoid fever responds to after the first week; it may be used to determine whether the infection is due to the Eberth's bacillus or the hæmatozoa of malaria.

Another means of diagnostic import in fever supposed to be typhoid is in the examination of the stools microscopically for the Eberth's bacillus; if it is found, it is evident the patient has enteric fever.

The serum diagnosis of typhoid fever has been undergoing investigation during the past year, but its practical usefulness is still an unsettled question. The difficulty in Widal's or Johnston's test, as well as others above mentioned, is that it requires an expert, and hence it is almost useless in general practice.

The discovery of the hæmatozoa of malaria by Laveran is at least next in importance to the discovery of the tubercle bacillus by Koch. It has given the medical profession an intelligent concept of malarial fever in its various manifestations, and the literature on this subject has already been cleared of an immense amount of rubbish which has enveloped the medical practice of the past.

The combined infection of Eberth's bacillus and the hæmatozoa of malaria seldom occurs, excepting as it may still linger in the mind of some medical hayseed, who, Rip-Van-Winkle-like, continues to hold fast to the opinion that malarial fever develops into typhoid fever, or is in some way dovetailed into it. On this question permit me to quote Dr. Osler, who states that "among the one thousand cases of malaria and the five hundred cases of typhoid fever which have been at my clinic, almost every one of which has had a blood examination, there has been but one doubtful case of double infection."

Double infection so infrequently occurs that it will seldom enter as a factor in the differential diagnosis between malarial and typhoid fever.

Dyspnœa of Uræmia.—

℞ Ether sulph. ..... ℥i.
S. Two or three teaspoonfuls in a little sweetened water.

Or ether can be administered hypodermatically in doses of two or three cubic centimetres, every three hours, and in the intervals it can be given by the mouth. It produces abundant diuresis and calms respiratory spasm.—LEMOINE *and* GALLOIS.

A NEW OPERATION FOR MALIGNANT DISEASE OF THE TESTICLE—THE NECESSITY OF A MORE EXTENSIVE OPERATION THAN CASTRATION FOR CARCINOMA, SARCOMA, ETC., OF THE TESTICLE.

By J. COPLIN STINSON, M.D.,

In deciding on an operation for malignant disease of the testicle, the problem is to remove the disease thoroughly. Castration is an operation which can be performed with very small danger to life, but whether for sarcoma or carcinoma the operation is not attended by large success, so far as complete cure is concerned. There is some evidence that it may be attended by permanent success, and there is still further evidence that the operation may be an excellent palliative measure, even when there is no cure. Thus in ninety-nine cases collected by Butlin there were four deaths from causes directly connected with the operation. Many of the patients were not traced, but there were five cases of sarcoma well at the end of from twenty months to two years, and two cases of carcinoma without recurrence at the end of forty-two months and one hundred and eight months respectively. While these results are encouraging, yet I am sure that with a radical operation still more encouraging results can be obtained. The objects of my paper are to describe an operation which will yield a greater number of permanent cures than will castration, and to report a case in which I operated by the radical method.

The following structures should be removed by operation in order to give our patient the best possible chance for permanent cure:

1. The diseased testicle and its coverings.

2. The portion of the scrotum containing the diseased organ, including in addition the raphe of the scrotum and the septum scroti.

3. The spermatic cord, its vessels, etc., as high as the internal inguinal ring.

4. The inguinal glands, fat, adhesions, etc.

The operation is performed as follows:

1. An incision is made from the external inguinal ring downward and inward to the beginning of the raphe of the scrotum. The cut follows the sulcus between the scrotum and penis. It is then carried downward and backward, parallel with and external to the raphe of the scrotum, and terminates at the scroto-perineal junction. The incision divides the tissues of the scrotum.

2. A second incision, which is slightly curved, is made from the external ring downward, following the sulcus between the scrotum and the thigh and the perineum. It terminates by joining the first incision at the scroto-perineal junction. This also divides the layers which form the scrotum.

3. The scrotum, the testicle, and its coverings, the median raphe, the septum scroti, etc., are as a mass freed from all their attachments except to the cord, up to the external inguinal ring. Any masses of fat, glands, adhesions, etc., should also be freely removed with these structures.

4. A third incision is made parallel with and about one-half an inch above Poupart's ligament, from the external ring to one-half an inch above the internal inguinal ring. It divides the structures superficial to the aponeurosis of the external oblique. The latter is well exposed and divided in the direction of its fibres to about one-half an inch above the internal ring. The cut edges are lifted and freed from the structures beneath, so as to expose the cord, etc., up to the internal ring. The cord, etc., are separated from the surroundings from the external ring to high up within the internal ring, care being taken also freely to remove all mass of fat, glands, adhesions, etc., in the rings and canal.

5. Make moderate traction on the cord so as to draw it out as far as possible from the internal ring, and secure it high up within the internal ring with a clamp. Divide below it. Any bleeding vessel or vessels are ligated separately with fine catgut. The raw surface of the stump is covered over by bringing together with continuous sutures of catgut the cut edges of the external coat of the cord. When the clamp is removed the sutured edges of the cord at once slip back into the abdomen.

6. The cut edges of the aponeurosis of the external oblique and the pillars of the external inguinal ring are brought together with continuous sutures of chromicized tendon or chromicized catgut.

7. The flap of skin covering the inguinal glands is dissected downward and all of the inguinal glands and fat removed. If the glands are adherent to the skin, the latter is also freely removed.

8. The flap is now replaced and the cut edges of the skin of the groin and the scrotum are united with fine silk sutures without drainage. A small strip of bichloride gauze may be inserted for a short distance in the lower angle of the scrotal wound and left in place for a day or so. All hemorrhage should be arrested before the wound is closed.

Dressings and after-treatment: Bichloride-of-mercury gauze or sterilized gauze is placed next to the wound. The dressing is held in position by long strips of adhesive plaster, then a layer of cotton, and then a firm spica and T-bandage. Care should be taken to avoid infection from urine and fæces; keep the patient in bed two weeks. Dress the wound on the seventh day or earlier, if there are indications when the silk sutures are removed. The firm dressings on the inguinal region are not removed till one month after the operation.

In June, 1897, I had an opportunity of operating on a patient for carcinoma of the testicle by this radical method.

History of the patient: Age, forty-five years; general condition good. In the last week of May or the 1st of June, 1897, he noticed that something was the matter with the left testicle, which was about twice the normal size. Some days afterward the skin in front of the body of the testicle broke down and a sloughy mass formed. It was not painful. I saw the patient June 23, 1897. Examination showed the left testicle enlarged to about three times the normal size, not painful or tender to the touch. In front and connected with the skin was a sloughy convex surface, about an inch and one-quarter in diameter. The mass was part of the testicle and bled freely on being picked with thumb forceps. The skin for about one-quarter of an inch around the protruding mass was moderately hard and indurated; the edges were raised and appeared to grip the mass. The cord was thickened. The glands in the left groin had been removed about a year before for chancroidal infection and abscesses. The prostate appeared to be normal for a man of his age. I made operation June 24, 1897. Chloroform was administered by the drop method by Dr. G. Gross. The steps of the operation were the same as described above, with two exceptions: the skin incision made from the external ring downward and inward to the penis, and external to the raphe of the scrotum, was carried higher on the root of the penis and encroached on the scrotal tissue of the normal testicle for about one-half an inch. This was done in order that the incision should be removed as far as possible from the indurated skin. No dissection was done for the removal of glands in the groin, as these had been extirpated about a year before. The stump of the cord was whipped over with

fine chromicized catgut. The cut edges of the aponeurosis of the external oblique and the pillars of the external inguinal ring were united with chromicized catgut sutures. The cut edges of the skin of the groin and the scrotum were brought together with fine catgut. A narrow strip of moist bichloride gauze was inserted for a short distance in the lower angle of the scrotal wound. This strip was removed thirty hours after the operation, and the dressings were reapplied. The wound healed by primary union. Recovery was uninterrupted. The patient will be kept under observation. I believe that in treating cases of malignant disease of the testicle a more thorough operation than castration should be performed.

In the radical operation I describe, the incisions are made wide of the diseased organ. The cord, etc., are removed as high as possible away from the testicle, while the thorough extirpation of the inguinal glands, fat, etc., also removes channels by the way of which infection might spread or in which infection is already present. No incision is made into diseased tissues, and thus secondary infection is prevented. The septum scroti and the raphe of the scrotum are removed, as they are formed by the junction of the series of coverings which invest the testicle and which make up the different layers of the scrotum. Even with such free removal of the scrotum there is quite sufficient of this tunic left, so that its cut edges can be brought accurately together without tension, and without making the slightest degree of pressure on the testicle. This is due to the extreme flabbiness of the scrotal tissues. There is every reason why this, the thorough operation, should be performed. It can be easily and quickly done. The mortality should be at or about *nil*, and I am sure time will show, if our cases of malignant disease of the testicle are operated upon by this radical method, that we shall have a large percentage of permanent cures.

THE TREATMENT OF HYDROCELE BY THE INSERTION OF STERILIZED CATGUT WITHIN THE TUNICA VAGINALIS.

BY GEORGE G. VAN SCHAICK, M.D.,

NEW YORK,

SURGEON AND PATHOLOGIST TO THE FRENCH HOSPITAL; SURGEON TO THE ST. VINCENT DE PAUL ASYLUM.

The treatment of hydrocele by the insertion of sterilized catgut within the tunica vaginalis is due to a French surgeon, to the best of my belief. I first heard of it in France a couple of years ago, but have failed to find the name of its originator.

The object of this operation is to cause an aseptic inflammation of the serous lining of the tunica, resulting in a modification of its secreting power. This is also obtained by the injection of iodine and other irritants, and by scoring the serous lining by means of nitrate of silver fused upon a probe. It would appear from the results I have obtained that the use of catgut is commonly followed by less pain than the other methods, and the success of the treatment is fully as good.

The technique consists simply in the following steps: Thorough disinfection of the scrotum, which is tapped with a small trocar, in order to secure a rather slow evacuation of the fluid. A catgut ligature of medium size is introduced within the cannula as soon as the serum begins to flow, and rapidly pushed within the tunica through the cannula, until about eight inches has passed through it. When all the liquid is evacuated the cannula is removed, and the catgut hanging out of the puncture is snipped off with scissors as close as possible to the scrotum. By manipulation of the scrotum we secure the complete entrance of the catgut within the tunica. The wound is then sealed with collodion.

If the asepsis has been perfect there is no possibility of the occurrence of any infection. The rather nauseating pain that sometimes occurs after iodine injections is commonly absent. No febrile movement occurs. I have so far observed nine cases, whose histories may be briefly given:

Case I.—A. W——, carpenter, aged forty-one years, had noticed a swelling for six months, but never did anything for it. The scrotum was tapped and the catgut inserted in October, 1894. Seven ounces of liquid flowed away. The next day the patient said he had felt rather uncomfortable during the night, but had no severe pain. A week later there seemed to be a slight amount of fluid in the tunica. This rapidly disappeared. Inquiry six months afterward revealed the fact that there had been no return.

Case II.—L. C. H——, lawyer, seen in November, 1894. He came to the office saying that his regular physician was out of town, and his hydrocele must be tapped at once. He had been tapped thirteen times before, the hydrocele having existed for eight years. He accepted my proposition to use the catgut. Nine ounces of fluid was evacuated. The operation was followed by slight occasional pain for two weeks. Inquiry in August, 1897, resulted in the answer that he had never had a recurrence.

Case III.—F. B—, saloon-keeper, has had a hydrocele for five years; it has been tapped six times. Insertion of catgut in March, 1895, appeared to cause more pain than usual, but the patient was very emotional. Fourteen ounces was evacuated. The man complained of sharp pain during the night, and insisted upon receiving a hypodermic injection of morphine. He said he felt much worse than after simple tapping, and remained in bed for four days. At the end of this time the tunica appeared to contain nearly as much fluid as before, and the patient was much discouraged. A fortnight later the fluid had all disappeared, and has not returned at the present writing.

Cases IV., V., and VI.—Each of these patients had a hydrocele of moderate size, and all were cured without any disagreeable complications.

Case VII.—F. R——, musician, has had a very large hydrocele for ten years, and thinks it has been tapped fourteen or fifteen times. In this case I used a rather large size of catgut (No. 6 instead of No. 3, as usual) and introduced about twelve inches. The operation was performed in October, 1896. Seventeen ounces of fluid was evacuated. The patient felt no pain until the next day, when he complained of a dull aching. Some fluid returned, and within a week the tunica appeared to contain about seven or eight ounces. The testicle then began to swell, and remained very large for three weeks, but caused no pain. At the end of this time, during which he was seen in consultation by Dr. James E. Kelly, this condition rapidly subsided, and the hydrocele has not yet recurred. During the whole time there was no evidence of sepsis, and I attribute the trouble to an exaggerated irritability of the parts.

Cases VIII. and IX.—These patients were both seen in February, 1897, and had hydroceles of moderate size. There was no recurrence after treatment.

One other patient operated on last month appears to be doing very well, but the case is too recent to be included in the list.

This little operation is one of great ease and simplicity, and certainly has given excellent results as far as I have had an opportunity to try it. No one who is not certain that he can obtain perfect asepsis in every detail should undertake it, but in careful hands it can

hardly give rise to any severe complication, and is worth trying in every case in which the Volkmann or other cutting operation is refused by the patient.

TROUBLES ARISING FROM PHIMOSIS, WITH REPORT OF CASES.[1]

By F. D. REESE, M.D.,

Oneland, N. J.

I do not intend to weary you with a long paper on this subject, for Dr. Sayre in 1870 and others since have written too well and explicitly for me to add to their accurate and exhaustive observations. But I believe that it is well for us occasionally to be reminded of the evils that are due to neglected phimosis.

Phimosis is an elongation and constriction of the prepuce, making it difficult or impossible to expose the glans penis. It is quite probable that convulsions are the most frequent complication due directly to this condition. As Peterson says, an infant is a bundle of nerves and nerve centres and reflexes, in a state of great activity, prepared to receive, store up, and re-energize a world full of new impressions suddenly thrust upon it. The continual irritation of the nerves from accumulation of confined smegma and subacute inflammation of the mucous lining of the prepuce overbalances the inhibitory action of the higher motor centres, and causes convulsions.

These are called reflex spasms, because the nervous irritation does not arise primarily in the higher motor centres, but in the peripheral nerves of the genital organs. Then, if this is the case, we as physicians, to be faithful to our charge, should examine the penis of every boy baby at his birth, and if there is a congenital phimosis or an adherent prepuce it should be relieved at the earliest opportunity. What is there more pitiable and lamentable than a confirmed epileptic?

Hare, in his essay on "Reflex Epilepsy," says: "Further than this, the mere temporary irritability of a cicatrix does not throw the patient into convulsion after convulsion immediately, but the convulsive condition, having once been begun by such a cause, may be brought back even when no irritation longer exists of an acute form, by some central disturbing mental condition entirely separated from the periphery."

What he says in regard to irritability due to a cicatrix is equally true of any other cause of irritation. And further, he says the law may be laid down as an almost unvarying one, that every nervous act is followed by other similar nervous acts, rapidly or slowly, according to the severity and frequency of the first acts; and if this predisposition be once set up, the subsequent acts may readily be excited by agents which primarily would have produced no effect.

Then, if this law be true, and I have no reason for disbelieving it, for experience confirms it, we should remove every irritation that might be a primary cause of convulsions, of whatever form or wherever found, whether it is a depressed portion of the skull, errors of refraction, tumors of the rectum, or congenital phimosis.

To show that congenital phimosis does cause reflex spasms, I will report the two following cases:

William W——, aged two and one-half years, family history negative, was always a colicky, crying baby, well nourished, but undersized; bowels regular. During six months the following symptoms developed: He became restless at night, jumping up in bed and staring as if frightened; also in the daytime he would stop and stare and lose himself for an instant. These spells soon developed into complete spasms, numbering three during the night and one every two or three hours in the daytime.

Upon examination I found a constriction of the prepuce, with adhesions to the glans penis. In the absence of any other pathological condition, I concluded the spasms were of reflex origin and due to the congenital phimosis and adhesions.

I operated April 23, 1896, freely exposing the glans and turning out the confined smegma. The spasms began immediately to occur less often, and on May 29th, one month and six days after the operation, he had his last spasm. Since then he has been as well and rugged as any child could be.

On December 5, 1894, I was called to see Master McD——, aged three and one-half years. He was born of healthy parents, but was very much under size and suffered from spasm of the right sterno-cleido-mastoid muscle, with head turned to the right, jerking of the eye muscles, and squinting. He complained of colic and had indigestion and malnutrition. He was also restless, irritable, and anæmic. An examination revealed a congenital phimosis and adhesions of the prepuce. I operated December 15, 1894. There was a gradual improvement from the first. While the boy is still small for his age, he seems perfectly healthy, with a tranquil disposition.

The following case illustrates the influence of preputial irritation upon the disposition:

Howard L——, aged twelve years, family history negative, is small in stature. He has a bright intellect, but formerly did not like to play with his mates of either sex, and was non-communicative and despondent. He complained to his mother of frequent and difficult micturition; he also said to her that he wished he had been made like other boys. He was brought to my office March 20, 1897. An examination revealed a very small penis, with almost complete closure of the prepuce, which was chronically inflamed. An operation was advised, and when the boy was informed of it he said he would gladly have it done if it would make him like other boys. The vesical irritation and difficulty in urinating were relieved at once by the operation, and his whole demeanor has been changed as a result. He has become more communicative and is developing into a leader among his companions.

I am led to believe from my own experience that in many cases hernia claimed to be of congenital origin is due directly to the straining caused by difficulty in urinating.

The next and last case that I shall report is unique, as far as I have been able to ascertain, for it illustrates the possibility and probability that phimosis is at times the primary cause of septicæmia.

Baby R—— was born July 15, 1896, of healthy parents, in normal labor. He nursed the mother's breast. I discovered that the infant had congenital phimosis and advised an operation, but the parents objected. Occasionally I saw the child, and found that he suffered from colic, difficulty in micturition, and constipation.

October 15, 1896, at 7 A.M., I was sent for. The patient had been vomiting, and this was followed by a sinking-spell. His extremities were cold and he was covered with a clammy sweat. The mother said he had been passing pus, tinged with blood, in his urine. The temperature was 102° F., the pulse was frequent, the boy was constipated, and his abdomen was tympanitic. I ordered oleum ricini and gave a digestive ferment; I also had him fed with sterilized cow's milk. There seemed to be no special change after the reaction from the sinking-spell until October 19th, when the patient began to take on an icteric hue.

[1] Paper read before the third district branch of the Medical Association of New York, Norwich, June 8, 1897.

Counsel was called and the opinion was given that it was a case of acute hepatitis. One-tenth grain of calomel was given every two hours, but was of no avail. The vomit became tinged with black mucus and the urine was freely mixed with pus. The child died October 21st, just six days after he was taken ill.

A post-mortem was held a few hours after death, Drs. Higgins and Watson being present. The body was well nourished, but jaundiced; the thoracic organs were healthy. On opening the abdomen the bowels were found empty of fæcal matter, but filled with gas. The stomach contained a little brownish-black mucus; otherwise it was empty. The liver was about twice the normal size, the gall bladder was normal, the spleen was slightly enlarged. The kidneys were lobulated, capsules slightly adherent; the pelves of the kidneys contained urine and pus, and the lining membrane was congested. The bladder was contracted, and its contents and the condition of its mucous membrane were the same as in the pelves of the kidneys. The microscope, in the hands of Dr. Higgins, revealed pus and blood in the urine and congested kidneys.

My theory of the cause of death in this case is as follows: The boy had congenital phimosis which confined the smegma, causing an irritation of the membrane of the prepuce, and finally suppuration, which infected the urethra. This infection extended along the urethra into the bladder, ureter, and pelvis of the kidney, and finally a general absorption of pus took place, causing septicæmia and death.

These cases and others that might be cited appear to enforce very strongly the importance of detecting and removing phimosis. Surgical treatment is often remedial in troubles that might seem very remote, and if generally applied to congenital phimosis would certainly prove in many cases the proverbial ounce of prevention which is better than the pound of cure.

Progress of Medical Science.

Pseudo-Tuberculosis Hominis Streptothrica.—Flexner reports the case of a colored man, seventy years old, presenting extensive consolidation of both lungs and symptoms generally of pulmonary tuberculosis. No sputum could be secured for examination. Death resulting, the lungs were found to be voluminous, but free from adhesions. The entire left lung, with the exception of the anterior edge of the upper lobe, was more or less perfectly consolidated. In those portions in which the consolidation was frank the lung presented an opaque appearance and was grayish in color, and softening had set in. Some of the cavities contained the products of disintegration, but all appearances of active encapsulation were wanting. Where the hepatization was less complete the pulmonary structure was œdematous and swollen, although perhaps not completely airless, and discrete tubercle-like nodules were visible. The pleura over the hepatized areas was covered with a fibrinous exudate. In the right lung the consolidation was less extensive and more focal in character. The pleural cavity contained a small quantity of pink-colored fluid in which floated flakes of fibrin. The intestines were moderately dilated. The omentum was rolled up, occupying a position beneath the transverse colon and extending across the abdominal cavity. The pelvis contained about half an ounce of fluid of brownish color and mucilaginous consistence. Between the loops of intestine were delicate shreds of fibrin. In addition smaller and larger nodules resembling tubercles, mostly translucent, were scattered irregularly over all the exposed peritoneal surface, being more uniformly distributed upon and within the thickened, rolled-up omentum. The liver and spleen on section exhibited similar nodules. Cover-slip preparations from the lungs stained by Gabbett's method showed no micro-organisms resembling tubercle bacilli. Stained with the carbol-fuchsin were numerous examples of a branching organism in many places collected into clumps or convoluted masses. Cultures from the left pleural cavity and the peritoneum remained sterile. Three separate sets of cultures were prepared from the lungs. In all at the end of twenty-four hours a vigorous growth of bacteria identifiable as belonging to the group of the bacillus coli communis had taken place. An inoculated guinea-pig showed no noteworthy local reaction, nor could the adjacent lymph glands be felt at any time. The animal, however, lost in weight, and died at the end of the seventh week. Upon post-mortem examination none of the lymphatic glands was found enlarged and there was no lesion resembling a tubercle in any organ. Cultures upon glycerin-agar made from several sources remained sterile. Cover slips from the serous cavities, the blood, and the viscera also yielded negative information. In cover slips prepared from the lungs at the time of the autopsy, as well as in sections, the micro-organisms, as stained by the ordinary methods employed for tubercle bacilli, with decolorization by acids, held the dye very loosely. The best method of staining proved to be Gram's or Weigert's modification for fibrin. Two kinds of lesions were present. In the peritoneal cavity tubercle-like nodules were found, consisting of epithelioid and lymphoid cells, with occasional granular cells. Necrosis by fragmentation was not uncommon in the centres of the tubercles, and fibrin, either before or coincident with necrosis, was commonly observed in the nodules. In the lungs also tubercles were present, but were less striking than was a diffuse exudation of leucocytes, plasma, and fibrin, which filled the air-cells, infiltrated the stroma, and tended to undergo necrosis, producing larger and smaller spreading caseous foci of degeneration. The number of masses of the streptothrix was very great and bore an intimate relation to the pathologic process. It is believed that the organism found present in the case reported is a new species, for which the name streptothrix pseudo-tuberculosa is proposed, and further that it is capable of causing in human beings a rapidly spreading and destructive disease resembling florid tuberculosis, for which the appellation of pseudo-tuberculosis hominis streptothrica seems warranted.—*Johns Hopkins Hospital Reports*, June, 1897.

Ulceration and Rupture of Gall-Bladder; Operation; Recovery. Verral (*British Medical Journal*, August 7, 1897, p. 341) has reported the case of a woman, forty-four years old, who had suffered for four days from pain over the upper part of the abdomen, together with nausea. The bowels had acted naturally, but the patient took a laxative. On the following day the bowels moved slightly, but the abdomen was somewhat swollen. Subsequent laxatives, as well as enemata, were, however, without effect. The woman had previously had several attacks of colic, with jaundice, which passed off after the taking of a laxative. She presented the expression characteristic of abdominal disease, and there was much distention, especially in the flanks, where there was also some dulness on percussion. The area of liver dulness was diminished and displaced slightly upward. There was a sense of hardness over the gall bladder. The abdomen moved with respiration. The rectum was empty and ballooned. Nausea was frequent. The tongue was furred but not brown. An incision five inches long, three inches above the umbilicus and two below, was made, and the cavity exposed. It was

bathed in bile-stained fluid, with flakes of lymph on parts of the intestines. On the under surface of the gall bladder was a round hole, about one-third of an inch in diameter; stones could be felt in the bladder, and a dozen or so of small and very sharp fragments and one small perfect stone were pressed through the hole with the fingers. No stones could be felt in any of the ducts. The whole abdominal cavity was searched, but no stones or fragments were found. All but one of the first row of stitches introduced to close the opening had to traverse the whole wall of the bladder, as it was too much thinned for Lembert stitches to hold. This row, being doubled in, was covered by Lembert stitches, taking a good hold, placed at right angles to the first row. The abdomen was freely flushed, a large glass drain carried down to the gall bladder, and the wound closed; but before the edges could be drawn even fairly close, the intestine had to be punctured and gas let out. Calomel was given and followed by a saline, and nutrient enemata were administered every four hours, with one or two teaspoonfuls of hot water by the mouth occasionally. The drainage-tube was removed after forty-eight hours, the gauze drain put into it having been frequently changed. Flatus was passed frequently, with and without a rectal tube. The bowels acted loosely twenty-six hours after the operation, and from this time nutrient enemata were necessarily given up, as they were not retained, and increasing quantities of milk and beef tea with brandy were taken by the mouth; and there was no nausea. The tongue remained moist and the abdominal distention gradually lessened. Suppuration took place around nearly all the sutures, but the wound was soundly healed in less than three weeks.

The Treatment of Coxalgia.—Jalaquier (*La Presse Médicale*, June 26, 1897) is opposed to resection, and thinks that this operation should be reserved for coxalgias complicated with constantly discharging fistulas or abscesses that have resisted punctures followed with injections of camphorated naphthol or of iodoform ether. The operations of the author have been atypical, and he never has felt sure that he has arrived at an entire curettage of the articulation. He agrees with Menard that preliminary injections create a condition favorable to the success of the operation. In the treatment of non-suppurative coxalgias he is not exclusive. In the hospital and where the patient can be closely watched he employs continued extension. When the pains have disappeared at the end of the seventh or eighth month he usually applies a plaster dressing and permits walking on crutches, having the patient wear a raised shoe on the healthy side. When the case cannot be attentively watched Dr. Jalaquier applies the plaster at first after resecting under chloroform, if the position is defective. The author agrees with Brun in saying that abscesses do not follow more frequently in children treated by this method than in those treated by continued extension. The author does not share the fears expressed by Kirmisson relative to resecting under chloroform a coxalgia in defective position with or without dislocation, but he emphasizes the statement that he does not employ this method in coxalgias complicated with abscess. When coxalgias are cured or almost cured in a defective position, subtrochanteric osteotomy gives good results. Of one hundred and twenty-two cases treated at the Trousseau Hospital sixty-seven have presented abscesses. Of the one hundred and twenty-two patients eleven died, seven of meningitis, four of pulmonary complications. This mortality rate is not accurate, as many of the children were not watched to the end. Of the one hundred and twenty-two cases forty-six were treated by simple continued extension, and it is curious that in this series we find five deaths from meningitis and four from pulmonary complications. Eighteen were treated by simple immobilization without resetting; they furnished two deaths from meningitis. Forty-one patients submitted to resecting under chloroform. In this series he found no deaths from meningitis or pulmonary complications. This may be due to good fortune, but the author thinks it is because he has never applied forced resection in children having abscesses or when the general condition was bad. As to the comparative value of camphorated napthol and iodoform-ether in the treatment of abscess, he states that eighteen abscesses were cured after sixty-eight injections of camphorated napthol, or an average of three or four punctures for each patient. Twenty-three abscesses were cured after fifty-two injections of iodoform ether, or about two punctures for each patient. Twenty-two abscesses were cured by the combination of the two agents. Abscesses that proved refractory under camphorated napthol were cured after several injections of iodoform-ether. For these reasons the author prefers iodoform-ether. Some abscesses thus treated become fistulous, but the proportion cannot be exactly given; this occurred only when the skin was ready to break spontaneously. The cure of these fistulas can be obtained if care is taken to avoid secondary infection and resort is had to frequent touchings with a solution of lactic acid, one in three.

Dilatation of the Stomach in Nursing Children.—Comby (*La Presse Médicale*, June 26, 1897) after having studied the symptoms of dilatation of the stomach in children of all ages, found opportunity to measure the gastric capacity on the cadaver in eighty subjects less than two years of age, and has been confirmed in his opinion as to the extreme frequency of dilatation of the stomach in poorly nourished infants. According to his observations the physiological capacity of the stomach, varying of course according to the height and weight of the children, will be as follows: At birth, 30 to 40 c.c.; first month, 50 to 60 c.c.; second to third month, 80 to 100 c.c.; three to six months, 120 to 150 c.c.; six to twelve months, 200 to 220 c.c.; one to two years, 300 to 350 c.c. The results of eighty-two autopsies made at the Hôpital des Enfants Malades, excluding those cases in which the stomach was altered and softened or so enormously dilated that it could not be measured accurately, he found: In twenty-six children from eighteen days to three months of age, six only had a normal or subnormal capacity, twenty had from double to triple the normal capacity. The minimum figures were 45 c.c. in a child of six weeks; in another of two months the condition was that of a newborn or premature child. The maximum was 300 to 310 in children of from two to three months, overfed and having considerable dilatation. Between these figures we find 150, 200, 260, which indicate a more moderate deviation. With nineteen children, aged from three to six months, we find four having a moderate or subnormal capacity. Two of these were fed at the breast and two were tuberculous. All the others had enormous stomachs reaching 300, 330, 340 c.c. or double the physiological capacity. Between six and twelve months six out of twenty-six had normal or subnormal capacity; these were children fed with more care than is usual, or of tardy development or tuberculous. A small and retracted stomach is often found in tuberculous children. Fourteen other children in this series gave capacities of 350, 400, 440, 480, 635 c.c. All these children were fed on the bottle and overfed. The remaining seven between one and two years had a gastric capacity of from 400 to 740 c.c.; this last figure was reached by a rachitic child of two years. As a result of these figures we see that a large majority of the bottle-fed children

entering the hospital have a more or less marked dilatation of the stomach. This dilatation of the stomach is responsible for a slowness in digestion and an autointoxication which results seriously. The use of the stomach pump six or seven hours after the injection of food has demonstrated the presence of curdled milk and putrid matter. At autopsy punctiform ulcerations of the mucous membrane are often found, together with serous products and blackish spots caused by capillary hemorrhage. This dilatation often plays an important part in the pathology of the nursing child and is often the direct or indirect cause of death. Lavage of the stomach with a Nélaton tube, No. 20, 22, or 24, according to the age of the child, is servicable, as it removes putrid food and has a soothing effect. If there is vomiting it usually ceases. Lavage is more easily performed in children than in adults.

The Serum Diagnosis of Typhoid Fever.—Guerard (*Journal of the American Medical Association*, July 3d) concludes: From an analysis of the results which have so far been obtained in the application of the Widal test, it would seem, in the first place, that the serum reaction is by no means specific, in the strict acceptation of the term. In the second place, it is evident that this test has certain limitations in its practical utility, and that unless properly applied with a due appreciation of these limitations it is liable to lead to false conclusions. The chief precautions to be observed in making the serum test are: 1. The virulence of the typhoid cultures employed. 2. The dilution of the serum. 3. The time limit for the reaction. The culture should be of high and known degree of virulence and the bacilli actively motile; the dilution should be in the proportion of at least 1 to 10, with a limit of fifteen minutes for the reaction to appear. Others recommend a dilution of 1 to 30 or 50, with a time limit of one or two hours, but, according to our judgment, there is no special advantage to be gained by using these higher dilutions. The possibility of error, which in either method is sometimes unavoidable, is in our method at least on the right side. It is better to err occasionally in giving a false positive diagnosis than by a negative result to exclude perhaps many true cases of typhoid. In our collective investigation it was found that sixteen of the forty-two observers had used the higher dilutions, 1 to 20 to 1 to 50, while twenty-six had adhered to the original 1 to 10 dilution of Widal. It should be remembered, however, that, aside from this possible source of error, the reaction may also be due at times not to a present but to a past case of typhoid so mild in character that it has been entirely forgotten. The absence of a reaction in any single case does not necessarily exclude the diagnosis of typhoid fever, as the reaction may be delayed till late in the disease. But if on repeated examinations no reaction appears, it is strong presumptive evidence of the absence of typhoid fever. Dried blood and fluid serum give very much the same results, but there is a decided advantage in the use of fluid serum, because the proportions in the mixture with the serum can be more accurately determined. The best mode of procuring the serum is by means of cantharides blisters. When the subject of the serum diagnosis of typhoid fever was first brought before the public, it was hoped that at last the long-sought infallible diagnostic test for typhoid fever had been discovered, which was at once rapid, simple, and suitable for clinical use at the bedside. With the non-fulfilment of these hopes, some physicians have come to look upon Widal's test as practically useless for diagnostic purposes. But, nevertheless, the results which have been obtained by many different observers with an extended application of this method of diagnosis would seem to warrant the conclusion that, in the hands of the expert bacteriologist, it is capable of rendering valuable assistance to the physician, along with the other signs of typhoid fever, in a large majority of cases, although, like other signs of disease, it is sometimes wanting or indecisive.

The Antitoxic and Therapeutic Activities of Human Blood after Recovery from Infectious Diseases.—It has been shown by numerous observers that the blood of convalescents from a number of the infectious diseases contains protective substances, and attempts have been made to use the serum obtained from such blood in the treatment of the respective diseases. Observations of a similar character, covering a period of about a year, have been made at the medical clinic of Professor Leyden at the University of Berlin, by Huber and Blumenthal, with especial reference to scarlet fever, measles, pneumonia, and erysipelas; and the results are embodied in a communication published in the *Berliner klinische Wochenschrift*, August 2, 1897. The antitoxic substances were obtained by mixing at once the blood (from one hundred to one hundred and fifty cubic centimetres) obtained by venesection with a like amount of sterile physiological solution of chloride of sodium, and adding one per cent. of chloroform. After the mixture was shaken and stirred it was put aside for twenty-four hours and permitted to stand, when it was gently expressed through sterile linen and finally filtered through sterile gravel. The resultant fluid was clear, of a dark-red color, was sterile, and remained so permanently on the addition of chloroform. If it be desired to remove the hæmoglobin, a second infiltration is practised, and the fluid then becomes lighter in color. The fluid was found to contain the specific antitoxic substances of the blood of convalescents, and it proved of equal antitoxic activity with serum prepared in the usual manner, while the amount obtained was almost twice as large. About one hundred injections were made, and in no instance did an abscess form. It was found that the fluid had no appreciable effect upon healthy persons. Temporary infiltration, with redness and sensitiveness, often appeared at the site of injection. Of thirteen cases of scarlet fever treated with the filtrate of blood obtained from convalescents, a distinctly favorable effect was observed in three. In the remainder the result was less positive, and none at all was noted in one. The temperature declined between the third and the sixth day in nine cases, as compared with the average of the sixth or the seventh day; reaching normal between the fifth and the tenth day, as compared with the ninth to the eleventh day. The duration of the disease was thus distinctly shortened. The injections were not rarely followed by a transitory elevation of temperature. No serious complication was observed in any of the cases. Of nine cases of measles treated with the filtrate of blood obtained from convalescents, a distinctly favorable effect was noted in two or three. In the remainder the result was rather doubtful. In none, however, was the critical defervescence deferred later than the third day. Of fourteen cases of pneumonia treated with the filtrate of blood obtained from convalescents, death took place in two; in eleven the crisis occurred between the third and the eleventh days. In four a conspicuous decline in the temperature took place following the injections, with improvement in the general condition. Similar results were not obtained with the filtrate of blood from convalescents from scarlet fever and from measles, and not in cases of other kinds treated with the filtrate of blood from convalescents from pneumonia. This filtrate from the blood of convalescents from pneumonia also proved capable of protecting rabbits from infection, although mice were not so protected. The conclusion is expressed that the blood of convalescents

from pneumonia contains antitoxic substances capable of specific activity with regard to pyogenous and other deleterious products of the disease, but not capable of causing or not present in sufficient amount to cause a definite crisis to modify appreciably the morbid anatomic process and to prevent extension of the disease. In ten cases of erysipelas treated with the filtrate of blood obtained from convalescents, no definitely favorable results were noted, and this is in accord with the opinion that antitoxic substances do not appear in the blood after an attack of this disease. Further, complications were not prevented, and the injections were followed by pain, redness, swelling, and infiltration. The fluid appeared, however, to have some local influence, inasmuch as the site of inoculation escaped involvement.

Calomel and Acids.—Ever since calomel was introduced into therapeutics classic authors have drawn attention to the minute precautions that its use requires if one wishes to avoid serious results. It is well known that this substance is unstable. Chemistry teaches that it is easily decomposed upon contact with salts and acids, and is transformed into corrosive sublimate. There are authors who will not admit the truth of this idea. They hold that the cases of poisoning observed are due to idiosyncrasies; others assure us that they have never found sublimate in the digestive tract; others again have a theory of intoxication, and think that the accidents arise from a reaction between calomel and albumin. The dangers that this drug presents cannot be contested, as the experiments of Ottolenghi prove. This author has given calomel in therapeutical doses to dogs and compelled them to drink salts and acids. The animals always presented symptoms of intoxication, which appeared with more rapidity and severity than if the calomel had been taken alone. In these experiments the symptoms were not the same as those observed after the ingestion of corrosive sublimate. Ottolenghi affirms that, contrary to the current opinion, calomel is not decomposed in the stomach; in fact, if we place calomel in solutions of salts or acids, no phenomenon will appear if the temperature is no higher than that of the body, 37° C. That which does not take place in the laboratory does not take place in the stomach in those cases to which we refer. The exaggeration of the toxic effect of calomel after the ingestion of salts or acids arises from the fact that its combination with albuminoid substances contained in the stomach will be facilitated and will yield products much more soluble, so that calomel, which is normally absorbed in very small quantities, will pass in much larger amounts into the circulation, thus provoking signs of grave intoxication.—*Gaz. Méd. de Liège*, June 24, 1897.

Antiseptic Properties of Bile.—Mayo Robson, in an article on "Diseases of the Gall Bladder and Bile Ducts" (London *Lancet*, May 29th), says: "It has been supposed that the bile is an antiseptic fluid which tends to prevent decomposition in the alimentary canal, but, in a series of observations which I published some years ago on a case of biliary fistula, I found that the absence of bile from the intestine of a woman during a period of fifteen months did not lead to any irregular fermentative process, showing that the alleged antiseptic effect of bile on the fæces is probably imaginary. Normal bile is, however, generally sterile. This was proved by Netter, in 1884, who experimented on dogs, and the fact has been confirmed by Gilbert and Girode and later by Naunyn, who found it sterile in two cases within a few hours of death. Frequent inoculative experiments on animals have confirmed these observations, thus explaining a well-known fact that in many cases bile has been extensively poured out into the peritoneal cavity without setting up peritonitis; but in disease of the gall bladder or bile ducts the bile is seldom or never sterile, and is capable of producing severe peritonitis. Bloch has demonstrated that the bile in cases of disease of the gall bladder or bile ducts always contains micro-organisms; hence he thinks it advisable to perform cholecystotomy in two stages, in order to avoid soiling the peritoneum and producing infective peritonitis. When the flow of bile along the ducts is arrested, micro-organisms often invade the gall bladder either from the blood or the intestine. Charcot and Gombault demonstrated the presence of organisms within it after ligaturing the common duct in dogs. This was confirmed by Netter in 1886, who found that twenty-four hours after aseptic ligature of the common duct in dogs, organisms, both staphylococcus and bacillus coli communis, could be cultivated from the bile. The bacillus coli communis exists normally in the human body, and is said to be the most abundant and most constant of the bacteria found in man in health. At one time, as shown by Escherich, it may act as an ordinary pyogenic organism producing local abscesses, at another as an active pathogenic germ producing fatal septicæmia. Mr. C. B. Lockwood found streptococci and other organisms, but no amœbæ coli, in an empyema of the gall bladder. Netter found staphylococci and streptococci present in pathological human bile, and Martin, Gilbert and Girode, and Bouchard have found the bacillus coli communis in the bile in cases of inflammation of the biliary passages. In acute or phlegmonous cholecystitis the walls of the gall bladder are swollen and œdematous, and may be infiltrated with pus. In three out of five of such cases Naunyn found the bacillus coli communis in the pus. Barbacci and others have shown that peritoneal sepsis may occur without perforation of the gut. The spread of infection through the walls of the gall bladder can readily be explained on the same hypothesis, showing how virulent peritonitis may arise in these cases, though there be no perforation. Gilbert and Girode found typhoid bacilli in the pus from a case of empyema of the gall bladder which came on as a sequence of enteric fever. Gilbert and Dominici also assert that they produced suppuration in the gall bladder and liver of rabbits by injecting a culture of typhoid bacilli into the common duct. These biological facts are borne out by the clinical observations of Dr. Murchison and of Dr. Hale White, who have found evidence of inflammation and ulceration in the gall bladder in well-marked and fatal cases of typhoid fever, there being no other cause than the specific disease to account for the trouble. Chiari investigated systematically a series of twenty-two cases of typhoid fever. With the exception of three cases, one of which was in the infiltrating and two were in the necrotic stage, he obtained typhoid bacilli invariably out of the gall bladder, and in fifteen cases they were obtained in pure culture. In thirteen of the nineteen cases in which a positive result was obtained there was inflammation of the gall bladder, with small-celled infiltration, œdema, and hyperæmia. In all twenty-two cases the diagnosis of typhoid fever was confirmed by cultivations from the spleen, mesenteric glands, or liver, or from the larger bile ducts. How do they reach the gall bladder? There are three possibilities: either they enter by the bile ducts, or from the blood, or directly through the wall of the gall bladder. The last-mentioned manner must be very exceptional. Their entrance from the blood has been apparently disproved, and it is therefore probable that they enter by the bile ducts. There is no doubt that the bacilli multiply in the gall bladder, and it is possible that they may be responsible for post-typhoidal cholecystitis, for gall stones, and also for relapses of the disease.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, October 30, 1897.

THE AMERICAN PHYSICIAN AS A PARTICIPANT IN FUTURE INTERNATIONAL MEDICAL CONGRESSES.

No one will gainsay the fact that the recent International Medical Congress in Moscow was a success from every point of view. It is probably the conviction of every participant that it was carefully and thoroughly planned, splendidly organized, and satisfactorily executed. Judged solely from the enormous attendance and from the amount and character of the work done, the meeting justified the existence of international reunions of this kind. From the purely scientific side alone, although there were no epoch-making communications, the sessions of the majority of the sections fully realized the expectations of the participants. Confronted with this knowledge, we are led to inquire what share the members of the medical profession of this country contributed to the success either by their presence or by their contributions. It has been stated that upward of one hundred physicians from the United States were in attendance, but this we believe to be entirely beyond the mark. It is very probable that the number of *bona-fide* physicians who participated in the congress from this country was not much above fifty. This estimate does not include medical students, reporters, and "doctors" of other kinds than medical. Numerically, therefore, the contribution from the United States was about one-one-hundredth of the entire body. This alone was a serious handicap in making their presence felt, but it is not to be compared with the obstacle offered by reading papers poor in thought and poorer yet in preparation. We would not be understood as saying that many of the communications presented by American congressists were not worthy of the audiences to which they were offered, and were not listened to with becoming deference. But this cannot be said of them all. It was noticeable, moreover, that although quite a large number of papers was announced by Americans, when the time came to read them the readers were thousands of miles away from Moscow. This happened in so many instances that the disagreeable thought came to one that this method at least had the advantage of bringing the writer's name prominently before the eyes of a few hundreds, yes, thousands of his colleagues, although the article in question might still be secreted in the recesses of his brain. It would seem that a man who informs the secretary of a society or a congress that a paper from his pen may be announced morally obligates himself to fulfil his engagement. Naturally there are many extenuating circumstances, but the fortuitous exigencies which prevent congressional participation usually do not arise so soon before the congress that the officials cannot be notified in time to keep the title of the recalcitrant's paper from appearing on the final programme.

It practically has been decided that the next international congress will be held in Paris during the opening year of the dawning century. The fact that a universal exposition, which is planned to surpass all predecessors, will be held there the same year, will undoubtedly attract a great number of our people, physicians among the rest. We believe that the time will be opportune for the profession of this country, participants in the prospective congress, to make their presence felt and to justify that reputation for brilliancy and integrity, not alone in practical fields, but in bacteriology, physiology, and hygiene as well, which they deservedly sustain at home and which they are partially accorded abroad. One or two hints at this time may be serviceable in contributing to such an end.

A physician should not presume upon the time and patience of his colleagues by reading a paper composed of truisms, some facts borrowed from text-books, and much padding. Such exhibitions contribute to international ill-feeling and to personal disdainment. No more should he report procedures based on alleged chemical or physiological experiments which he is not ready and able to demonstrate by chemical or physiological tests. Above all, he assiduously should refrain from announcing papers that he does not anticipate being able to present. This latter procedure has already been done to death. If he will take the results of his honest work and intelligent thought, it matters not whether they be based on experimentation or observation, he may be assured of kindly reception and courteous attention. Moreover, he will have the satisfaction of feeling that he is doing for the reputation of the profession in his country what his Latin confrères did so conspicuously at the last congress, enhancing its scientific position.

THE YELLOW-FEVER SITUATION.

THERE are no signs of improvement in the yellow-fever situation in the South as yet, the number of new cases reported in New Orleans each day being between fifty and sixty, and until a frost or a notable fall in temperature occurs, of which there is no present prospect, little improvement can be hoped for. The area of infection continues also to spread, cases having been discovered during the past week in Memphis, Tenn., and Selma, Ala., and consequently the territory of the shotgun quarantine, with its prostration of trade and financial loss, is constantly widening. The exodus that ensued upon the announcement that the fever

had invaded Selma furnishes a typical illustration of the unreasoning fear that possesses the minds of people in times such as these. The panic that seizes upon everybody the moment a case of yellow fever is discovered in some hitherto unvisited place is almost incredible, and would be ludicrous were it not pitiable. On Saturday last it was announced that some cases had occurred in Selma, and by Sunday evening all but about three hundred of the white inhabitants of the city had left it, over $12,000 worth of railway tickets having been sold in that time. The regular passenger service was insufficient to take away all the fugitives, and many special trains were made up to accommodate those who were clamoring for a means of escape from the pest. These trains, once filled, were run through the State without stopping, every little hamlet having its guard at the station to shoot any one who would attempt to leave the cars. Atlanta is the city of refuge for all these frightened men and women, and such numbers have gone there that it is feared it will soon be impossible to find accommodations for them. Many of those who cannot get as far as Atlanta or some Northern city are camping out in tents or huts in the woods, having isolated themselves completely, fearing to let a human being approach, lest he bring the dread pestilence with him. The death rate in the present visitation has been remarkably low, but this seems to have had no effect in calming the apprehensions of those who have been exposed or fear they may be. The psychology of this epidemic will make an interesting study.

In the *Herald* of recent date is a cable despatch from Buenos Ayres, giving the results of an interview said to have been had with Sanarelli in Montevideo concerning his curative serum. According to this account, the serum is useful solely as a curative agent and is unavailable as a means of protection against the disease. He said he had tried to immunize dogs, horses, and other animals, but the method was slow and uncertain. In the way of a cure of yellow fever, however, he claimed that his experiments had been successful in animals, though he had been unable as yet to make a practical test on man. "This new serum," the report continues, "if compared with other serums intended for preventive or curative purposes, will be found to be far above them in efficacy, though it is not yet perfect. Before announcing his final conclusions and the composition of his curative serum, Dr. Sanarelli will try to make a more potent serum for experiment on a fever patient. He will soon leave Montevideo for Rio Janeiro, where he will continue his experiments."

It is rather difficult to tell, from this report, just what the serum is or what it is expected to do, and we shall doubtless have to wait until Sanarelli arrives in Genoa, to which place the Italian papers state he is now on his way, before knowing what stage he has reached in his experiments looking toward the elaboration of a curative or prophylactic serum.

The Pasteur Monument Fund, so it is announced, has reached the very satisfactory sum of $60,000.

THE FAVUS QUESTION.

As will be noted in our news columns, the authorities in Washington have taken the timely and wise step of ordering that immigrants affected with that loathsome, contagious, and highly undesirable disease, favus, be excluded from our shores.

The position which the RECORD took in this matter over two years ago makes this action highly gratifying to us, to say the least. We have fought to exclude the disease as one wholly unnecessary for us to add to our already long list of exotics. In view of a failure in this direction we have urged that it be kept out of the schools and out of the barber shops. It is now being quite generally excluded from the schools in this city, but how many children of foreign birth are endangering, not perhaps the lives, but possibly the lifelong happiness of our American schoolchildren throughout the country no one can tell. In an editorial upon the "Increase of Favus" in the MEDICAL RECORD of June 1, 1895, we pointed out that while in 1877, so far as reports were available, there were but thirty-two instances in the whole country, sixty had been reported from this city alone in 1893.

We said at that time that it was a great mistake not to keep these children from landing in the country, and that, if they could not be stopped at quarantine, some means of segregation should be instituted. An alarming increase of late would seem to be indicated by the statement of a recent correspondent in the MEDICAL RECORD, who has observed over eighty instances in one dispensary during a period of five months.

The following is the closing sentence of our comment two years ago:

"This is much too young a country to compete with the old world in the matter of favus statistics, and there should be a quick return to the good old times when New York could boast but four instances of the disease."

May not the MEDICAL RECORD's plea have had an influence in bringing about the praiseworthy action just taken by the national government?

THE ASEXUALIZATION OF CRIMINALS.

FOR many thousands of years among civilized people and savages alike, one of the most difficult problems to solve has been "what to do with confirmed criminals." At this date the solution seems as far off as ever. The methods of punishment by the ancients were strictly deterrent. No mercy was shown the delinquent, but he was punished for his sin with the greatest severity. Possible reformation by less harsh means did not enter into the question. With the advent, however, of the Christian era, more merciful treatment was introduced, and now in some countries the inmates of prisons are better housed and fed than the honest poor. Notwithstanding all this, the most sanguine of penologists can hardly say that the results have been commensurate with the efforts, and probably the present system is no more successful than the old one of severe punishment. We have several times re-

ferred to the few reformers who contend that society must organize to prevent by means of asexualization the propagation of degenerates and criminals. Dr. Barnard Eastman recently read a paper before the Kansas Medical Society at Topeka, upholding these views, but, after all the arguments which he advanced in support of this drastic measure, he is forced to the tame conclusion, that "the practical difficulties which would be encountered in attempting to carry out this theory, with that disregard of fear or favor necessary to its success, are at present insurmountable."

DEATH FROM GENERAL ANÆSTHESIA.

Many deaths occurring as the result of the administration of general anæsthetics undoubtedly are not widely heralded and some may not even be reported as due to this cause. Three instances of sudden death during anæsthesia have occurred in a single New York institution within the current year: two from chloroform and one from ether.

A recent issue of *The Hospital* calls attention to the alarming frequency of deaths from anæsthesia in England, especially from chloroform. At the time of writing there had been twenty-two cases reported in three months, and at the time of going to press four more deaths from this cause had been made public. One naturally wonders in how many cases the true cause of death has been concealed. In *The Hospital* of April 24th, there are reported seven additional cases collected from the daily papers, four of these having been reported in one day. In one instance the jury found that death was due to excitement in anticipation of the operation. In regard to this finding we call attention to the investigation of Dr. Leonard Hill, who says: "Chloroform paralyzes the splanchnic vasomotor tone just as shock does, and in the condition of shock or emotional fear the compensatory mechanism for the effect of gravity is almost abolished, and chloroform may easily be the last straw to paralyze completely the circulation. It is, no doubt, in this way that an expectation of disaster has sometimes conduced to its occurrence." Again, the *Hospital Nurse's Mirror* of April 3d reported a case from the Windsor Royal Infirmary, of a nurse who collapsed suddenly under gas and ether, while having some teeth extracted.

A few figures taken from the statistics of Goult as a result of a collective investigation of the German Surgical Society of Berlin, as to the number of deaths from the various anæsthetics and their combinations, may be of interest. During the five years, from 1890 to 1895, there were 88 deaths from chloroform out of 2,286 cases, 7 deaths from ether out of 6,020 cases, 1 death out of 10,162 cases in which chloroform and ether were combined, 1 death out of 5,744 cases in which chloroform, ether, and alcohol had been used.

Would it not be more scientific to have an honest report of deaths from anæsthetics and a more careful study of the subject of anæsthesia? These reports bespeak likewise the need of a more careful examination of the patient before the administration of an anæsthetic. The duty of administering an anæsthetic in hospitals usually falls to some recent graduate or to the junior member of the staff. His practical knowledge of the subject is usually very limited, and the operator, being aware of this, feels it necessary to have an eye upon this part of the work, when he ought to be able to concentrate his entire attention on the operation. So far as we have been able to learn, the Philadelphia Polyclinic is the only institution that has appointed an instructor especially for the purpose of training the hospital staff and students in this branch of medicine. We are not in favor of carrying specialism to extremes, but, as we have stated on one or two previous occasions, there is room for a few specialists in anæsthesia, as only a physician who is thoroughly acquainted with the work and has had practical instruction and experience should be chosen for this important part of a surgical operation.

SPECIAL INSTITUTIONS FOR THE TREATMENT OF PULMONARY TUBERCULOSIS.

More is probably known of the etiology and pathology of pulmonary tuberculosis than of any other disease, and it will be thought, considering this minute knowledge, that the ravages made by consumption might be curtailed to a greater extent than is now the case.

The treatment of phthisis in special institutions has met with a large measure of success abroad, as our readers may have gathered from the discussion on this subject at the Moscow congress, and there would appear to be no reason why similar establishments should not have a like success in this country. The rational method of treating tuberculosis is, without doubt, for the sufferer to live under those conditions which fulfil in the highest possible degree the laws of hygiene and diet. In private life, except by the very rich, these conditions are very difficult to attain. Climate and situation, which play so prominent a part in the curative treatment of lung affections, are naturally important in the choice of a site for a sanatorium, and as the climate in many parts of this continent is peculiarly favorable, these objects are easily obtained.

UNAUTHORIZED AUTOPSIES.

The very laudable eagerness for autopsies in cases of doubtful cause of death very often tempts hospital internes to strain a point to gratify it. A recent case in point is reported from the Hahnemann Hospital in this city, in which such an examination was made without the permission of the immediate relatives or friends, and without an order from the coroner. While there can be no question as to the motive of the act on the part of the participants, it is nevertheless quite evident that they exceeded their authority in the premises and became liable for prosecution. The trouble was initiated by the undertaker, who informed the widow that an autopsy had been performed upon the body of the deceased, and that in consequence the corpse was not fitted for exhibition at the funeral. While it does not appear, from the standpoint either of reason or of fact, that the mere examination of the

brain and the necessary removal of the calvarium would cause notable disfigurement, the original and unwarranted assumption of responsibility for the act itself is none the less apparent.

If the facts are as stated in the preliminary court examination, the parties involved in the affair are technically guilty before the law. Whether or not the case be brought before the grand jury, as has been threatened, the discussion of the principle upon which the charge of misdemeanor is founded is timely and proper, in view of the constant temptation to dodge the law in the interests of pathological science. In cases of doubt as to the real character of the disease causing death, and when an autopsy is denied by the friends of the deceased, the physician can decline to give a death certificate; but he can go no further without permission from the coroner, to whom all such doubtful questions should be referred. It is always better to be sure first than to try to explain afterward.

News of the Week.

The Detroit Medical and Library Association.—At the annual meeting held on October 4th, Dr. Andrew P. Biddle was elected president.

The Public Library (consolidation of Astor, Lenox, and Tilden) has secured the services of Dr. John S. Billings in the preparation of a complete catalogue.

Schools of Midwifery in Chicago will be affected, it is said, by the recent ruling of the State board of health that all medical instruction must hereafter be carried on in the English tongue.

Favus Subjects Excluded.—Immigration and customs officials have been informed by a circular just sent out by Commissioner-General Powderly that they are henceforth to send back immigrants affected with favus.

The Department of Charities, finding that the city is supporting about twice as many would-be paupers as is necessary for the city to pay for, has begun to cut down salary expenses by discharging nurses, druggists, and examining physicians.

Dr. Ludwig Weiss has been appointed consulting dermatologist to the Hebrew Orphan Asylum in this city.

A Dinner to Sir William Gowers.—The members of the Society of Medical Stenographers in England have decided to celebrate by a dinner the conferring of knighthood upon the founder of the society, Sir William Gowers. The dinner is to be held on the 25th of November, and Sir William Broadbent has expressed his willingness to take the chair on the occasion.

Obituary Notes.—Dr. Jacob Hay died at York, Pa., on October 18th, at the age of sixty-four years, in consequence of disease of the stomach and heart, from which he had long suffered. He was graduated from the University of Maryland in 1854, and he was a member of county, State, and national medical societies. He had been president of his local medical society, and had for several years been a member of the local board of school control. He had also served as a member of the board of pensioner examiners, and he was a member of the Masonic fraternity.

A Medical Service at St. Paul's Cathedral in London.—At the request of the Guild of St. Luke a sermon to the members of the medical profession was preached in St. Paul's by the Archbishop of York on October 19th. The service, which was held in the evening, was largely attended by the medical men of London, all wearing academical costume and accompanied by the ladies of their families.

Johns Hopkins University.—There are one hundred and seventy medical students at the Johns Hopkins University. Some of them are women. Dr. Michael Foster, professor of physiology in the University of Cambridge, England, delivered an address before the students on October 11th.

Diphtheria and Typhoid in Maryland.—The prevalence of diphtheria and typhoid fever in various parts of Maryland has given the State board of health an increase of work. There has been complaint at Cumberland on account of the contamination of the Potomac River from places above Cumberland. This same contamination has had a very bad effect on the drinking-water of Washington.

Maryland Association of Military Surgeons.—The various staff surgeons of the militia of Maryland have formed a permanent organization, called the Maryland Association of Military Surgeons.

Our Lucrative Profession.—There are nearly four hundred doctors in St. Louis who are practically starving, says Dr. Lamphear, and in Brooklyn physicians are said to be hiring as motormen. Dispensaries and patent medicines are the alleged causes.—*The Medical Examiner.*

Against Lodge Physicians.—It is stated that the Quebec College of Physicians and Surgeons has issued a decree prohibiting medical men from accepting positions as physicians of charitable or benefit societies, under pain of withdrawal of the privilege to practise.

Sanarelli in Italy.—The Rome correspondent of *The Lancet* writes that Dr. Sanarelli, the discoverer of the bacillus icteroides, is expected shortly at Genoa, whence he will start on a series of visits to the leading medical schools in Italy, at each of which he will deliver a lecture on his discovery of the bacillus of yellow fever and set forth his maturer recommendations for the prophylaxis as well as treatment of this disease.

Medical Society of the County of Broome (N. Y.).—The annual meeting of this society was held in Binghamton on October 5, 1897. Dr. J. D. Appley reported a "case of chronic abscesses following typhoid fever," Dr. W. S. Overton one of "chorea complicating pregnancy," and Dr. L. D. Farnham two of "cancer of

the breast cured by operation." A communication on "Hypnosis and the Phenomena of Consciousness," presented at the last meeting by Dr. W. A. White, was discussed. The presidential address was delivered by Dr. B. E. Hadeker.

Dr. W. F. G. Hunter, of Kentucky, who was recently acquitted of the charges of bribery in the senatorial contest in that State, has been appointed by President McKinley United States minister to Guatemala.

Small-pox is prevailing to an alarming extent in Larnaca in the island of Cyprus, and many of the inhabitants are fleeing from the town to the open country in hope of escaping infection.

Cincinnati Justice.—Not long ago a woman was arrested in Cincinnati for riding a bicycle. She was modestly dressed and was behaving properly, yet the Solon of the police court fined her fifty dollars and sentenced her to the workhouse for thirty days on a charge of loitering. The woman was a prostitute, but it is a strange law that punishes a person engaged in the pursuit of health and happiness on a wheel. Riding a bicycle will become a dangerous pastime if one can be accused, in so doing, of loitering as well as of scorching.

Those Printers again.—A local paper, speaking of a street accident, says: "Dr. Jones was quickly summoned, who, after examining the patient's purse, decided that the case was hopeless."—*Medical Times.*

The French Urological Association held its second annual meeting in Paris on October 21st, 22d, and 23d, under the presidency of Professor Guyon. The questions proposed for discussion are: 1. "The Operations Performed on the Testicle and its Adnexa for the Relief of Prostatic Hypertrophy," to be introduced by Drs. Albarran and Carlier. 2. "Non-Gonococcic Urethritis," to be introduced by Drs. Eraud and Noguès.

A Plea for a Department of Public Health.—At a meeting of the board of trade and transportation, held in this city on October 13th, Dr. Warren E. Anderson, of Pensacola, formerly a member of the Florida State board of health, read a paper advocating the creation of a United States department of public health independent of the treasury, war, navy, or any other department of the national government. He said that "uniformity of quarantine laws and regulations can be obtained only through Federal control. This is greatly to be desired, as it alone can prevent the wild, reckless, and absurd shotgun quarantines, allay panics, restore confidence, and prevent commercial rivalry of seaports in their greed for trade from endangering the public health of the entire country. The State should be represented in the national health councils, and the laws there made should be executed through this representative. All sanitary or quarantine officials should be residents of the State whose health interests they are to protect, and no official should be appointed in the way of political preferment, but only upon personal qualifications approved by commercial organizations where such exist. The foreign tonnage tax should be applied to the purposes of quarantine, and thus relieve the people and the commerce of the country from the heavy and unjust burdens laid upon them by the present system of health protection. The Marine Hospital service should be remanded to the performance of that duty which it has so faithfully done for the past hundred years—the care of sick and disabled American seamen. A failure upon the part of the Federal Congress to provide the citizen with adequate protection against the invasion of imported disease and the prevention of the recurrence of such scenes as are being enacted along the lower Mississippi Valley and the Gulf coast, will be regarded as a national calamity."

College of Physicians of Philadelphia.—At a stated meeting of the section on general medicine of the College of Physicians of Philadelphia on October 11th, Dr. C. W. Burr read a report of two cretinoid brothers. Dr. S. M. Hamill read a paper on "The Condition of the Salivary Digestion in Anæmia." The investigations upon which the paper was based led to the conclusion that there were no constancy and no distinctiveness in the characters and properties of the saliva under the various conditions of anæmia. Dr. D. L. Edsall read a paper on "The Gastric Conditions in Anæmia," in which he pointed out essentially that while in cirrhosis the acidity of the gastric juice is likely to be increased and in pernicious anæmia to be diminished, the condition of this secretion bears no constant relation to the state of the blood. Dr. J. C. Wilson exhibited the brain from a man who was originally supposed to be suffering from typhoid fever, with the development finally of cerebral symptoms. Death ensuing, an accumulation of pus was found in the region of the vermiform appendix, and also an intracranial abscess containing some six ounces of pus, situated between the dura and the brain, actually involving neither of these, and included within a dense pyogenic membrane.

Philadelphia Pediatric Society.—A stated meeting of the Philadelphia Pediatric Society was held on October 12th. Dr. F. A. Packard demonstrated a number of cases exhibiting congenital deformities of the extremities. Dr. C. W. Burr read a report of a fatal case of chorea occurring in the course of an attack of nephritis following scarlet fever. Dr. T. S. Westcott described a simple method for calculating the quantities of cream and whole milk to make any formula for home modification. Dr. Alfred Hand, Jr., reported a case of scurvy in a child.

Hospital Diagnosis.—A barkeeper in London felt out of sorts and had a rash on his face. He applied for treatment at the outdoor department of one of the large hospitals, and was told that his blood was poisoned in consequence of his frequent nibbling of potted meats and fish at the lunch counter. He returned to work and stopped nibbling, but got no better and returned to the hospital. This time he was told he had small-pox and was bundled off to the pest-house, his neighbors and patrons of the dive where he

dispensed wet goods being thrown into a state of consternation. While they were bemoaning his lot and theirs he suddenly reappeared, having been assured at the small-pox hospital that his case was one simply of varicella. Now the hospital authorities are investigating the hospital doctors, and threaten to dismiss them for their blunder: the inevitable result will be a falling off in the number of patients, and consequently a less effective appeal to the charitably disposed.

Pathological Society of Philadelphia.—A stated meeting of the Pathological Society of Philadelphia was held on the evening of October 14th, the president, Dr. J. H. Musser, in the chair. Dr. D. Riesman demonstrated a specimen exhibiting extensive gelatinous infiltration of all parts of the peritoneal cavity, together with a considerable quantity of gelatinous material derived from this source. The morbid process was believed to be a form of colloid carcinoma. Dr. H. W. Cattell exhibited the stomach and kidneys from a case of carbolic-acid poisoning. The former presented a characteristic lustrous silvery appearance. It was pointed out that occasionally the odor of carbolic acid can be perceived about the kidneys when not detectable about the stomach. The president delivered his annual address and the treasurer read his annual report. According to the latter the receipts during the past year, including a balance on hand of $1,318.91, amounted to $2,225.81, and the disbursements to $1,198.29. The number of active members of the society is two hundred and seven. An election for officers was held, with the following result: *President*, Dr. W. E. Hughes; *Vice-Presidents*, Drs. F. A. Packard, C. W. Burr, Alfred Stengel, John Guiteras; *Secretary*, Dr. D. Riesman; *Recorder*, Dr. A. E. Taylor; *Treasurer*, Dr. T. S. Westcott; *Curator*, Dr. J. D. Steele.

Expulsion from a Medical Society for Unethical Conduct.—The Cumberland County Medical Society, at its semi-annual meeting at Bridgeton, N. J., on October 12th, expelled from its membership Dr. S. M. Wilson, a graduate of the University of Pennsylvania and a practitioner of twenty-eight years' standing, for unethical conduct in acting as physician for a company engaged in the employment of a proprietary cure for alcoholism.

"The National Medical Review."—With the October number of this interesting journal Dr. Charles H. Stowell retires from the editorship, and will be succeeded by Drs. Thomas E. McArdle and George W. Johnston. Dr. Stowell has made a most readable paper, and his successors will have no sinecure in maintaining the high standard he has set, though we have no doubt they will do so. We wish the retiring editor full measure of success in his new field of usefulness.

Philadelphia County Medical Society.—A stated meeting of the Philadelphia County Medical Society was held on October 14th, the president, Dr. James Tyson, in the chair. Dr. E. W. Holmes read a paper on "Hay Fever," in which he maintained that the disease was a neurosis dependent upon disorder of terminal nerve filaments in the nares, the exciting agent consisting of some form of fine powder, such as the pollen of plants, etc. Of treatment he could not speak hopefully, but recommended change of residence.

D. Hayes Agnew Memorial Pavilion.—This new addition to the hospital of the University of Pennsylvania was opened at Philadelphia on October 15th, with appropriate ceremonies. The building is a substantial three-story brick structure, with a front of one hundred and fifty-four feet and a depth of one hundred and eighty-four feet. Its erection cost $150,000, and it has a capacity of one hundred and twenty beds. It includes also an amphitheatre with a seating capacity of two hundred and seventy, and two others with a capacity of one hundred and twenty-five each, together with hospital wards, dispensary rooms, etc.

Prof. Rudolf Heidenhain, the well-known professor of physiology at the University of Breslau, died October 13th, at the age of sixty-three years. After receiving his diploma in 1854 he entered the laboratory of Professor DuBois-Reymond, under whose direction he conducted his researches into experimental physiology. He had held the chair of physiology at Breslau since 1859.

A Midwife Fined.—A midwife was recently arrested here on the charge, made by the County Medical Society, that she practised medicine without a license. She was convicted and made to pay a fine of $50.

The Anniversary of Pasteur's Death was celebrated on September 28th in Paris. The members of the staff of the Pasteur Institute met in the crypt and placed wreaths on the tomb. On the same day a mass was celebrated in the presence of the family in the parish church at Arbois, Pasteur's birthplace.

The Surgeon-General of the Navy.—The President has appointed Medical Director William K. Van Ripen to be surgeon-general of the navy, to fill the vacancy caused by the death of Dr. Bates. Dr. Van Ripen is a graduate of the New York University Medical School in the class of 1862.

The Plague is steadily increasing in India. It is officially announced that an outbreak has occurred in the Jalandhar district of the Punjab. The village of Khartkarhalan, the seat of the infection, has been cordoned. In the hospitals of Poonah two hundred and ninety-four cases of the plague are being treated, and the physicians are attending one hundred and fifteen cases in the Bombay hospitals. There were forty-two deaths at Hardwar up to October 26th. Thus the disease is now prevailing in the interior as well as on both the east and west coasts of the Indian peninsula.

The People's Baths.—According to the annual report of the New York Association for Improving the Condition of the Poor, of the work done at its People's Baths, No. 9 Centre Market Place, the number of baths taken from October 1, 1896, to September 30,

1897, inclusive, was as follows: Men, 75,454; women, 12,935; children, 12,634; total, 101,023. The increase over the corresponding period of 1896 was 7,215. The total number of baths taken since the work began was 502,675. A fee of five cents is charged, which entitles the bather to a new piece of soap, clean towels, and the use of a compartment for twenty minutes.

The Microbe of Trachoma.—It is announced from Vienna that one of the university professors there has discovered the specific diplococcus of Egyptian ophthalmia.

Segregating the Consumptives.—The State board of health of California has issued orders directing physicians in charge of asylums to segregate consumptives and report the number in each asylum. This is preliminary to the enforcement of stringent rules by the board for segregating consumptives in all health resorts. Many persons in Southern California have been clamoring for such action. The southern counties are overrun with consumptives, and in most places they are a menace to healthy persons.

Another Jack the Ripper.—France has a "Ripper," who can give points to the English Jack of former days. He has confessed to twelve of the nineteen murders he is supposed to have committed.

Diphtheria prevails to such an extent in a part of Hoboken that it has been found necessary to close one of the public schools, interrupting the studies of over one thousand children.

Explosion on a Warship's Launch.—Dr. W. R. Dubose, two other officers, and a number of the men of the battleship *Texas* were injured by the explosion of the boiler of one of the steam launches of that vessel in Boston Harbor, on Friday last. No one was killed, but several of the sailors were seriously injured.

Dr. Laporte, whose misfortune in losing a patient in childbirth, after he had performed craniotomy with a packer's needle, as told by our Paris correspondent, was convicted on October 22d of homicide, and was sentenced to three months' imprisonment. The sentence appears from the evidence to have been a most unjust one, and the unfortunate has the comfort, slight though it may be, of knowing that he has the sympathy of his confrères everywhere.

The President's Physician.—It is reported in Washington that Capt. Leonard Wood, passed assistant surgeon of the army, will probably succeed the late Surgeon-General Bates of the navy as medical attendant to President McKinley. Dr. Wood is stationed in Washington as attending physician to army officers and their families. He was appointed to the army as assistant surgeon from Massachusetts in 1886.

Dr. Van Fleet, of this city, was sued for libel in consequence of some remarks made by him at a meeting of the County Medical Society, concerning the advertisement of an optician in the *Medical Register*. The case has been recently tried and resulted in the acquittal of Dr. Van Fleet. Judge Wallace ruled that there was nothing in the advertisement to cast reflection, but, as Dr. Van Fleet was seeking the removal of the advertisement before a body competent to grant it, his remarks constituted a privileged communication; and further, there was nothing to show personal malice on the part of Dr. Van Fleet. He directed the jury to bring in a verdict for the defendant.

The Hodynsky Plain Disaster.—The commissioners appointed to inquire into the disaster on the Hodynsky Plain in Moscow during the coronation festivities, have reported that the number of lives lost was fourteen hundred and twenty-nine.

"United Statestians" is the uncouth appellation which the editor of the *Practitioner* gives us, at the suggestion of some anonymous word-coiner. The inhabitants of this glorious country are very well satisfied to be called Americans, but if some jealous Canadian objects we would modestly suggest the designation "United Statesmen."

Physicians for Bombay.—The Indian government has asked for twelve medical men to be sent out from England to the Bombay presidency for duty in the plague-stricken districts. The conditions of engagement are: £25 for expenses previous to starting, a free passage to Bombay and back, and 500 rupees a month.

Injured by Kissing.—A curious tale is related in the *Münchener Nachrichten* of a man who lost consciousness after implanting thirty-seven hundred and fifty kisses upon a young woman's lips in the course of three hours. He had made a wager that he could kiss his sweetheart ten thousand times within ten hours, but soon realized the universal truth that there can be too much of a good thing.

Alcoholism in the Army.—The annual report of Surgeon-General Sternberg, made public, says that alcoholism is not so prevalent as it was in the army, but the improvement has been slight. The admission rate for intemperance was 29.08 per 1,000 for the army as a whole, 31.20 among the white soldiers, and 5.70 among the colored soldiers. Seven deaths among the whites were due directly to alcoholism.

Deaths from Starvation in Cuba.—Dr. Brunner, medical inspector of the Marine Hospital service stationed in Havana, reports to Surgeon-General Wyman that the death rate in Havana is enormous and that the sanitary conditions in the city are going constantly from bad to worse. About two-fifths of the total deaths are due to the lack of sufficient food among the country people, whom Weyler's infamous and inhuman policy has driven into the city. Dr. Brunner writes, in the latest report of the Marine Hospital service: "An inspection of a pest hole, known as Los Fosos, was made by me on Thursday, October 14th. This place has been set aside for the country people sent to Havana. Los Fosos consists of a large wooden building, about one hundred and fifty feet in length and sixty in width.

The building is situated in an inclosure which is used for the storing of carts of the municipality. There were five hundred people found in and around this building, and of that number over two hundred were found lying on the floor, sick and dying. I saw no child under ten years of age who could be considered in good health. They were invariably suffering from some form of enteritis or dysentery. The emaciation of their bodies was startling. This place is not a hospital, but simply a place of residence for these people, and a conservative estimate of the death rate would be about ten per day. The number is recruited by fresh accessions from the country. There were over one hundred and fifty children below the age of ten years, and I did not observe one whose chance for living thirty days, under the existing conditions, was good. There are two other such places in the city where the same conditions exist." The hospitals of the city are frightfully overcrowded, the Mercedes, for example, having five hundred patients while it has accommodations for only two hundred, and now they are forced to refuse to receive any new patients.

To Test the Antiseptic Treatment of Typhoid Fever.—In response to the suggestion of a correspondent that the value of the antiseptic treatment of typhoid fever be put to a careful scientific test, Dr. Woodbridge writes, in the *Journal of the American Medical Association*, that he will cheerfully accept the conditions. He says he will meet the suggested commission "whenever it may command my services and wherever it may choose to hold its sessions, whether in some typhoid-stricken city in the United States, in England, on the Plains of Thessaly, or wherever the disease may occur; only show me the patients and I will supervise the treatment of as many cases of typhoid as may be necessary to enable the commission to make a final and decisive report. No one shall be taxed either for my services or for my expenses." Another writer in the same journal suggests that the Paris Academy of Medicine be asked to make the inquiry.

Obituary.

DR. WILLIAM H. FORD,

PHILADELPHIA, PA.

Dr. William H. Ford, president of the Philadelphia board of health, died suddenly of heart disease at his summer home at Belmar, N. J., on October 18th, at the age of fifty-eight years. He was graduated from Princeton College in 1860 and from Jefferson Medical College in 1863. He was in 1862 appointed acting medical cadet in the United States army, being stationed at the Wood Street United States Army General Hospital in Philadelphia. Later he was detailed as medical officer on board the hospital steamer *Whildin* in the Pamunkey River, where he continued in sercive for a short time, when he was again stationed at the Wood Street Hospital, remaining there until the spring of 1863. In the following summer he was appointed assistant surgeon of the forty-fourth regiment, Pennsylvania volunteers, and soon afterward he was made surgeon. He remained with his regiment until the defeat of General Lee after the battle of Gettysburg, when he was mustered out of service. In 1863 he was elected resident physician in the Philadelphia Hospital, and in the following year he was re-elected. In 1865 he went abroad and spent three years in general and medical study. In 1868 he began the practice of medicine in private, and from 1869 to 1871 he was assistant demonstrator of anatomy in the Philadelphia School of Anatomy. During the Centennial exposition in 1876 he was a member of the Centennial medical commission of Philadelphia, being also chairman of the committee of this body on sanitary science. In the same year he was a delegate to the International Medical Congress held at Philadelphia. In 1871 Dr. Ford became a member of the Philadelphia board of health, in 1875 its secretary, and in 1877 its president, continuing in the latter office until his death. During his connection with this board he planned and had issued a weekly bulletin of vital statistics of Philadelphia. He was largely instrumental in organizing the odorless system of cleaning wells, the public collection of garbage, and in establishing a department for regulating house drainage in Philadelphia. The organization of a department of milk inspection was also due to his efforts. In 1893 Dr. Ford planned and supervised for the board of health the construction and fitting up with all modern appliances of a large pavilion hospital for the treatment of cholera and contagious diseases in conjunction with the Municipal Hospital. He took an active interest in the construction of a large and complete disinfection plant at the Lazaretto, and proposed the erection of a hospital for tuberculosis at this station. In 1876 Dr. Ford was elected physician to the Foster Home. In 1879 he was made a member of the board of managers of the Sanitarium Association of Philadelphia, and in the same year he became a member of the board of directors of the Tenth Ward Charity Society and was elected chairman. Dr. Ford was the author of a thesis on "Gunshot Wounds of the Chest," founded upon his experience in military hospital wards. From 1872 to 1876 he edited the reports of the board of health, and from 1872 to 1875 he compiled the vital statistics of Philadelphia. He was the author of "Statistics of Births, Marriages, and Deaths in the City of Philadelphia," published in 1874. He was for several years one of the associate editors of the Philadelphia *Medical Times*.

PASSED ASSISTANT SURGEON BRATTON.

MARINE HOSPITAL SERVICE.

Passed Assistant Surgeon William DuBose Bratton, of the United States Marine Hospital service, died at Sabine Pass, Tex., on October 2d, under peculiarly distressing circumstances. In the need of medical officers during the present yellow-fever epidemic, Dr. Bratton, though an invalid and therefore on waiting orders, voluntered his services to meet the emergency. He was ordered to Sabine Pass to assume charge of matters relating to the quarantine service at that port. On October 1st he had been superintending the disinfection of a vessel, and, returning to the ship to reassure himself upon the work done, he fell through a ventilating-hole, striking his head on an iron knee, producing concussion of the brain. He remained undiscovered for several hours, and when found was unconscious and remained so until death occurred, eighteen hours after the accident. He was born in South Carolina, June 23, 1860, and was graduated at the Medical College of South Carolina, March 1, 1884, and for the year following was house surgeon at the Charleston City Hospital. He entered the Marine Hospital service in 1885, his first station being in this city.

Reviews and Notices.

VITA MEDICA: CHAPTERS OF MEDICAL LIFE AND WORK. By SIR BENJAMIN WARD RICHARDSON, M.D., LL.D., F.R.S. London, New York, and Bombay: Longmans, Green & Co. 1897.

THESE chapters upon incidents in the medical and scientific life of the autobiographer will have for his admirers a peculiar interest in the fact that only two hours after their completion the author was seized with the illness which ended fatally three days later.

The work is published, therefore, fresh from the pen without the author's revision or correction. It is somewhat pathetic to read, in the preface, written so short a time before the end, that some studies of like nature were still in hand, but that he had thought it best to issue at the present time what he had dared to imprint upon these pages. Chapter xxviii., page 496, the shortest in the book, is entitled "A Last Word," in which he said: "I have set myself to record a medical life from the medical side of my own life; not in any sense as a model picture, but in the earnest hope of the day when men of physic shall find in the study of the natural body the grandest work the human intellect can command."

DIGEST OF CRITICISMS ON THE UNITED STATES PHARMACOPŒIA, Seventh Decennial Revision (1890). Published by the Committee of Revision and Publication of the Pharmacopœia of the United States of America, 1890–1900. Part I., Comprising Abstracts of Papers up to July 1, 1896. New York. 1897.

THE committee on revision has here presented in a hundred and eighty pages the first portion of the digest of criticisms and suggestions for improving the National Pharmacopœia.

A TEXT-BOOK OF MENTAL DISEASES, FOR THE USE OF STUDENTS AND PRACTITIONERS OF MEDICINE. By THEODORE H. KELLOGG, M.D. New York: William Wood and Company.

THE time is particularly opportune for the appearance of an authoritative American treatise on mental diseases. The author of the text-book before us has embraced the opportunity, and the result is a volume that enhances at the same time his reputation as an alienist and littérateur, and advances the deserved position of American psychiatry. No one acquainted with the literature of insanity and who has had intimate contact with the insane can fail to be impressed by the fact that the author has made himself intimately familiar with both, and has given forth as the result a distinctly individual and praiseworthy treatise. The volume of about eight hundred pages is divided into two parts, the first being concerned with general mental pathology, the latter with the special groups and the typical forms of insanity. Under the former are discussed the history, the statistics, the nosology, the etiology, and the evolution, stadia, clinical progression, and termination of mental diseases. The symptomatology is then taken up in great detail; first, the psychical, then the somatic symptoms, the different subdivisions of each being considered in a separate chapter—for instance, under the former, disorders of the intellect, of the emotions, and of volition; under the latter, the disorders of the various systems making up the body. The pathology, diagnosis, prognosis, and treatment are then considered before the special forms of insanity are discussed. The arrangement of the volume leaves nothing to be desired. The subject is unfolded in a natural way, and for the beginner in psychiatry the work cannot fail to be impressive, suggestive, and very useful.

In the chapter on the nosology of insanity the author recites the various classifications that have been given by psychiatrists, and then points out the necessity of a new classification based particularly on etiological ground, which he proceeds to give. The virtues of Dr. Kellogg's classification are very apparent to the reviewer; nevertheless he believes that serious objections can be urged against its adoption. It is unwieldy and too complex for all save the psychologist and advanced psychiatrist; in short, a classification of insanity that befits a text-book for students and practitioners should be simple, lucid, and as brief as possible, even though these qualities are opposed to absolute scientific accuracy and detail.

The chapter on the etiology of insanity is comprehensive, well put together, and one of the best. The same may be said of the chapter on treatment, by all means the best one in the volume. It is doubtful if any more reliable guide can be put in the hands of the inexperienced physician or the developing alienist than the chapter now under discussion. It is stamped throughout with the hallmark of one who has come into intimate association with the insane under three very different conditions, viz.: in private life, in public institutions, and in sanatoria. The advantages and disadvantages of each are specifically and judiciously set forth. The chapter on the prognosis of insanity is clearly the work of one who has lived with the insane and whose conclusions are based on the experience such intercourse has given. In other words, one is convinced that the conclusions of the author are not the mirroring of work in the library. The author is apparently alive to the value of simple statement and of emphasis, and does not indulge in the latter when the former is sufficient. The chapter on the pathology of insanity is brief, devoid of illustration, and disappointing. It is the only chapter in the book that does not reflect credit on its author. The formula for the diagnostic examination of patients will no doubt fulfil the expectations of the author, who believes "that it may prove highly suggestive and useful to the general practitioner," providing the latter can have Dr. Kellogg's book before him when he is examining a patient, but the general practitioner will probably find his strength unequal to memorizing it.

That Dr. Kellogg has made one of the most important additions to text-book literature of insanity must be apparent to every one who carefully examines this volume. We believe that it will become a standard for American students. It is not without serious inherent shortcomings, and a number of minor deficiencies, syntactical, orthographical, and other, might have been eliminated by careful proofreading. Although the style of many passages is very impressive, the reviewer has a feeling after finishing the volume that oftentimes the phraseology is unnecessarily learned and weighty, and although moderately familiar with the literature of the subject which the book so commendably exposits, still he found it necessary on more than one occasion to lean on an encyclopædic dictionary, and in one instance that staff failed him.

A MANUAL OF PHYSIOLOGY, WITH PRACTICAL EXERCISES. By G. N. STEWART, M.A., M.D. With numerous illustrations. Philadelphia: W. B. Saunders. 1897.

THE author herein gives the result of years of teaching physiology to medical students. A series of practical exercises is given, which are well adapted for practical work in a laboratory. In fact the book should be used only as a guide for work in the laboratory. All the various chapters on the blood, lymph, respiration, digestion, nervous system, the senses, are clearly written, and the instruments described are up to date. The illustrations are excellent, and the book is certainly a credit to the writer.

SIR JAMES Y. SIMPSON. By EVE BLANTYRE SIMPSON. Famous Scots Series. New York: Charles Scribner's Sons.

THIS tells in a pleasing style of the school days, start in life, rise, popularity, honors, hospitality, religion, failings, etc., of a man whose life must have something of interest in it for every physician.

A TEXT-BOOK OF SPECIAL PATHOLOGICAL ANATOMY. By ERNST ZIEGLER, Professor of Pathology in the University of Freiburg. Translated and Edited from the German Edition by DONALD MACALISTER, M.A., M.D., Linacre Lecturer of Physic and Tutor of St. John's College, Cambridge, and HENRY W. CATTELL, M.A., M.D., Demonstrator of Morbid Anatomy in the University of Pennsylvania. Sections I.–VIII. New York: The Macmillan Company. London: Macmillan & Co., Limited. 1896.

THE present volume includes eight sections: section i., blood and lymph; section ii., the vascular mechanism; section iii., the spleen and the lymph glands; section iv., the osseous system; section v., the muscles and tendons; sec-

tion vi., the central nervous system; section vii., the peripheral nervous system; section viii., the skin.

Volume II., when published, will contain the pathology of the alimentary tract, liver, pancreas, respiratory and genito-urinary systems, eye, and ear.

The translation has been done with evidences of the utmost care and attention to detail. The illustrations are excellent, and the publishers' portion of the work is all that could be desired.

TELEPATHY AND THE SUBLIMINAL SELF. An account of Recent Investigations Regarding Hypnotism, Automatism, Dreams, Phantasms, and Related Phenomena. By R. OSGOOD MASON, A.M., M.D., Fellow of the New York Academy of Medicine. New York: Henry Holt and Company. 1897.

THE new psychology, as it is called, has an attractiveness about it which brings forth writers and readers.

The present series of papers give studies in the outlying fields of psychology, and is intended as an aid and introduction to the study of "the more subtle forces in our being." Interesting material will be found in the chapters on thought transference, lucidity, double personality, automatism, crystal gazing, phantasms, etc.

A TREATISE ON THE SURGERY OF THE ALIMENTARY CANAL, COMPRISING THE ŒSOPHAGUS, THE STOMACH, THE SMALL AND LARGE INTESTINES, AND THE RECTUM. By A. ERNEST MAYLARD, M.B., B.S. Lond., Surgeon to the Victoria Infirmary, Glasgow, etc. Pp. xxiv. + 724. Philadelphia: P. Blakiston, Son & Co. 1896.

IT is impossible in a brief review to do justice to this elaborate exposition of the subject of gastric and intestinal surgery. Some idea of the scope of the work may be obtained from a glance at the table of contents and list of case reports, from which it will be evident that the author has gone most expansively into the literature of the subject, American as well as foreign. Apparently no important case has escaped him.

Part I., on the œsophagus, includes sixteen chapters, neoplasms being most thoroughly discussed. Among the many admirable plates is one excellent skiagraph (p. 24).

In Part II., on the stomach (fourteen chapters), we note as especially worthy of study the two chapters on ulcer, two on pyloric and cardiac obstruction, and the descriptions of gastrostomy and gastrectomy.

Part III., dealing with the intestines, includes nearly three hundred pages, and is exhaustive. Three chapters are devoted to appendicitis, and a large number of operations for entero-anastomosis are carefully described and illustrated. More than a hundred pages are given to the rectum.

Each division of the subject is introduced by a chapter on anatomy and physiology. The pathology, symptoms, and prognosis of each lesion are first presented, followed by the treatment. The operations are described in separate chapters, the descriptions being clear and concise, with the omission of all useless details. Each subject is thoroughly elucidated by the introduction of clinical reports of cases.

Many of the illustrations (one hundred and seventeen in number), are unusually valuable. In fact there seems to be little room for criticism, unless the busy reader may object to a certain amount of "padding" in a book which is supposed to be devoted purely to operative surgery. But the temptation to write a bulky, rather than a practical working monograph, seems to be what most medical writers find hard to resist.

THE MENOPAUSE AND ITS DISORDERS. By A. D. LEITH NAPIER, M.D., F.R.C.S. Ed., M.R.C.P. Lond., F.R.S. Ed., etc., Senior Surgeon and Surgeon in charge of Gynæcological Cases, and Lecturer in Clinical Surgery and in Gynæcology, General Hospital, Adelaide, etc. Pp. xv. + 307. London: Scientific Press, Limited. 1897.

AS stated in the preface, the aim of the author is to set forth the results of the latest studies in menstruation and the phenomena attending its cessation.

There are thirteen chapters, each of which is succeeded by a copious list of references. The introductory chapter on menstruation is quite interesting, considerable attention being paid to modern theories. The author leans to the "nerve theory," fortifying his position very well. The succeeding chapter on "Anatomical Considerations" is an able one. The author's theory is briefly as follows: The action of the uricular glands causes a peripheral uterine irritation which sends afferent impulses to the nerve centre regulating menstruation. Thence efferent impulses are sent to the uterus, determining continued growth of the glands, stroma, and vessels. The menstrual flow is due to the breaking down of congested capillaries and shedding of the superficial epithelium. The rhythm of menstruation is due (1) to metabolic changes in the endometrium, followed by katabolic changes for the removal of effete matters; (2) to periodic enlargement of the uterine glands; (3) to automatic nerve action.

In chapter iii. the physiology of menstruation is discussed at length; in chapter iv. the normal climacteric; chapters v. to ix. (inclusive) deal with its ordinary disorders, blood dyscrasias and constitutional affections, and the psychoses; Chapters x. and xi., on fibroids and malignant disease, are exceedingly interesting and will repay careful study; the concluding chapter treats of vaginal and uterine displacements in elderly women.

We have no hesitation in commending this monograph as the best which has yet appeared on this important subject. It is not only original, but presents special points of excellence, notably the clear scholarly arrangement of the material, the summary which concludes each chapter, and the exhaustive bibliography. The therapeutical side of climacteric disorders, which has hitherto received but little attention, is carefully handled, and will be especially helpful to the general practitioner. In this age of overproduction in medical literature, it is always gratifying to meet with a book which needs no apology, but is its own *raison d'être*.

AN ACCOUNT OF THE LIFE AND WORKS OF DR. ROBERT WATT, Author of the "Bibliotheca Britannica." By DR. JAMES FINLAYSON, M.D., Physician to the Glasgow Western Infirmary and the Royal Hospital for Sick Children. With a Portrait. London: Smith, Elder & Co. 1897.

A NEAT little volume of forty-inch thick paper and large-print page, having a delicately tinted frontispiece portrait. An appendix contains dates of interest in Watt's life.

OBSTETRICAL POCKET-PHANTOM. By DR. K. SHIBATA, Specialist in Gynæcology and Obstetrics, Tokio, Japan. Preface by Professor Franz von Winckel. With eight illustrations, one pelvis, and two jointed manikins. Translated from the third edition by ADA HOWARD-AUDENRIED, M.D., Physician to the Children's Clinic at the Woman's Hospital, Philadelphia. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street. 1895.

THE twentieth century approaches. Its advent is heralded by a work written by a Japanese professor and translated by a medical man of the gentler sex. To be sure it is small, but then, too, it is good,—and a small good thing often shows in what direction the wind is pushing the world along. Students will find this an aid in the study of parturition.

NEW YORK COUNTY MEDICAL ASSOCIATION REGISTER FOR 1897.

THIS book contains the names and addresses, with office hours, of the 1,056 members of the New York County Medical Association, and also the names and addresses of all other regular physicians in this city. In addition to these lists the book contains much valuable information concerning medical laws, etc., and several short essays on topics of current interest, one of which is a brief statement of the advantages to be derived from the adoption of Modern Greek as the international language.

A SYSTEM OF SURGERY. By American authors. Edited by FREDERIC S. DENNIS, M.D., Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical College, New York, President of the American Surgical Association, etc.; assisted by JOHN S. BILLINGS, M.D., LL.D., D.C.L., Deputy Surgeon-General U. S. A. Profusely illustrated with figures in colors and in black. 8vo, pp. 908. Philadelphia: Lea Brothers & Co.

THE third volume of this valuable work appears with commendable promptness, and contains a large amount of interesting and practical material. It comprises chapters on the surgery of the larynx, tongue, jaws, teeth, salivary glands,

neck and chest, eye, ear, skin, genito-urinary system, and syphilis, and may be considered as a collective work mostly in special lines. In a general way it may be said that each author has done his best to present his subject from the authoritative standpoint of an expert and with due consideration for the purposes of the work as a whole. Dr. D. Bryson Delavan's chapter on the Surgery of the Larynx and Trachea is a judicious *résumé* of the subject, well written, clearly presented, and practically considered. The Surgery of the Mouth and Tongue, by Professor Mudd, compasses a large field, and each portion receives its due attention. The descriptions of pathological conditions and operative procedure are clearly and concisely presented. The Diseases of the Salivary Glands forms a short and practical paper by Professor Porter, of Harvard. The Surgery of the Neck, by Dr. Willard Parker, gives evidence of an earnest study of the subject, but with too much apparent deference to other surgical authorities. The editor, with the universal adaptability of his kind, assigns himself to a passing emergency by treating in a thoroughly *ex-cathedra* fashion the Surgical Injuries and Diseases of the Chest. Professor De Schweinitz, of Philadelphia, gives an excellent chapter on the General Diseases of the Eye, which will be especially appreciated by the general surgeon, while Drs. Noyes and Weeks treat the Operative Procedures on the Eye in a thoroughness of manner and detail leaving nothing to be desired. The Surgery of the Ear, by Dr. Bacon, makes an interesting and instructive chapter within the short limits of its assignment of space. The Surgical Diseases of the Jaws and Teeth, by Professor Tiffany, is a thoroughly scientific presentation of principles and practice too little known and appreciated by both the general practitioner and the dentist. The chapter on Surgical Diseases of the Skin, by Professor Hardaway, of St. Louis, has a good selection of the varieties of the subject, and treats them in an intelligently practical manner. Professor J. William White, of Philadelphia, assisted by Dr. W. H. Turner, contributes an exhaustive section on Genito-Urinary Diseases, making almost a book by itself, and Professor R. W. Taylor, with an equally elaborate and painstaking chapter on Syphilis, closes the volume. The usual number of illustrations embellish the book, a good proportion of which are in colors.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 21, 1897.

EDWARD G. JANEWAY, M.D., PRESIDENT.

The Wesley M. Carpenter Lecture.—DR. WILLIAM HALLOCK PARK delivered the lecture, which was the special order of the evening, taking for his subject, "The Contributions of Bacteriology to Therapeutics." He said that bacteria caused disease by their mechanical presence in the tissues, by the poisons produced in their growth, or by the withdrawal from the body of their food substances, or in other ways, as yet unknown. They caused injury to the body chiefly by their action on the body cells through their poisons. The most important determining factor was whether or not the body at the time and place of infection was in proper condition for the growth of the bacteria. Ordinarily, the human body was not a good place for bacterial growth. We must look to the living tissues for some decided influences in addition, otherwise it would be impossible to offer a reasonable explanation for the very variable degrees of virulence exhibited. It was long ago noticed that people were not apt to contract certain diseases a second time. If a few virulent anthrax bacilli were injected into a susceptible animal, the bacilli would soon begin to increase, and would give rise to fever and other evidences of disease, and finally cause death. More minute examination would reveal the fact that the bacteria apparently attracted great numbers of leucocytes; in an immunized animal no such phenomenon would be observed. This attraction of the leucocytes by bacteria was not due apparently to any inherent property of the leucocytes, but rather to the effect of substances in the serum on the leucocytes. Besides this action of the leucocytes, it was probable that the blood contained substances directly bactericidal. As to the nature of the action of toxins and antitoxins on each other, it might be stated, as a working hypothesis, that a toxin was a substance directly poisonous, according to the intensity of its affinity for the cell substance of any living body. Thus, a chicken might be injected with three times as much tetanus toxin as would be fatal to a horse, and still the chicken would live; but sufficient could be injected to cause its death. According to his view of the subject, an antitoxin might be defined as a toxin which, by contact with living cell substance, either within or without the cell, had been changed. The toxin might have been changed by uniting with a portion of the cell substance, or might have been simply acted upon by it. He could not conceive of cells being so constituted as to have a response for each specific toxin; but if we considered the antitoxins to be toxins altered by contact or union with the cells, the specific action was easily explicable. As these substances had not been obtained in a pure state chemically, we could only theorize regarding them. Antitoxins do not remain permanently in the blood, but are gradually eliminated, disappearing after a few weeks or months. Bacteria differ as to the portions of the tissues in which they can develop. Thus, a few tetanus bacilli driven by a splinter into the foot multiply but slightly, but they find sufficient soil to produce a toxin quickly, and in sufficient quantity to cause death. The bacillus of diphtheria requires a different soil; it is practically harmless in the skin and intestine, but when inhaled causes diphtheria. The tubercle bacillus invades the tissues very slowly. Clinically, as well as bacteriologically, it was known that lack of food, exposure to heat and cold, overexertion, extreme youth, and other influences predispose to disease, while the opposite conditions help the body to protect itself.

Tetanus.—The lecturer then took up the consideration of a few of the more important diseases. He said that since the advent of aseptic and antiseptic surgery tetanus had become less frequent in operation wounds, but a sufficient number of cases were still reported annually in this locality to make the disease of practical importance. The tetanus bacillus was now accepted as being the cause of all the various forms of tetanus —puerperal tetanus, tetanus neonatorum, idiopathic and traumatic tetanus. There must always be some wound in which the bacillus could find lodgement. At one stage of the development of the bacillus it contained a very resistant spore. The tetanus bacilli had been found very commonly in the soil, in horse and cow manure, and in hay. The tetanus bacillus remained at the seat of infection, and did not spread through the body; hence, the disease was a true toxæmia. In practice, the infection was usually one of the tetanus spores, and these spores required special conditions for their development. Early and thorough cleansing of even seemingly insignificant wounds was an important prophylactic in those regions in which tetanus was common. The toxins in the wound were almost as dangerous as the bacilli themselves. Tetanus antitoxin had been applied practically on a large scale in immunizing animals against possible tetanus. This plan had been adopted among the animals kept by the board of health for experimentation, and in this way it had been possible materially to reduce the mortality among these animals. Some operators favored giving an immunizing dose of tetanus antitoxin before performing an operation on a valuable animal, such as a horse. The results of the cura-

tive treatment were not so brilliant as those of immunization; hence the great importance of such prophylaxis. After the appearance of the first tetanic symptoms, the administration of the tetanus antitoxin was ordinarily useless, in both the lower animals and in man. When the incubation period was long, the results were much better. Dr. Alexander Lambert had found that in thirty-one cases developing in eight days after infection the mortality was 61.3 per cent., while in similar cases not treated with the tetanus antitoxin the mortality was estimated to be as high as eighty per cent. From the available statistics, it seemed certain that the tetanus antitoxin possessed a certain curative effect. From twenty to fifty cubic centimetres should be given, twice daily, in all cases of tetanus, and the treatment should be begun at the earliest possible moment.

Diphtheria.—Diphtheria antitoxin had been singled out among the antitoxins because of its success in the treatment of diphtheria. The great mass of physicians was at the present time convinced that diphtheria antitoxin, in doses of from two hundred to three hundred units, would confer immunity against diphtheria for from two to four weeks, and that the period could be lengthened at will by a repetition of the injections. They were also convinced that when cases were seen early, and before general poisoning had ensued, the antitoxin could be relied upon to arrest nearly all cases of diphtheria. In the more advanced cases, as seen commonly in practice, it was fair to state that the antitoxin treatment greatly reduced the mortality, in both pure and mixed infections. The speaker fully indorsed the view held by Drs. Biggs and Girard, viz., it mattered not from what point the subject was regarded, only one conclusion could be reached, and that was that there had been an average reduction of mortality of not less than fifty per cent., and, under the most favorable conditions, a reduction to one-fourth, or even less, of the previous death rate. This had occurred in different seasons and different countries, and always in proportion to the extent of the use of the antitoxin. The experience with diphtheria antitoxin very naturally led to the question: "Why should tetanus and diphtheria antitoxin differ so greatly in their curative action?" The answer was to be found in the fact that the tetanus toxins developed unnoticed for a number of days, and the disease was only detected only after general poisoning had taken place; whereas the diphtheria poisoning started on the surface, and before its toxins had been absorbed there was abundant evidence of the presence of the disease. The hope had been expressed that it would be possible to avoid the rashes that sometimes follow the administration of diphtheria antitoxin, but there was no more hope now than five years ago of separating the antitoxin from the horse serum. We had, however, a much more concentrated serum, and, therefore, less horse serum was introduced at a dose. By better attention to the selection of the animals and to their general condition, we might hope to obtain a diphtheria antitoxin so pure as to give practical immunity from these unpleasant complications. In the dried antitoxin we had a preparation which could be preserved indefinitely. The dose of diphtheria antitoxin, in the curative treatment of diphtheria, should be from one thousand to three thousand units, according to the severity of the case and the age of the patient, and this dose should be repeated in from twelve to eighteen hours if no improvement was noted or the case remained severe. Dr. Park stated that the absolute mortality from diphtheria in New York, Paris, and Berlin was lower than last year. Formerly, the death rate in Berlin had been 80 per 100,000, now it was 26; in Paris, the average death rate had been 63, but last year it was only 17, and this year also 17; in New York, the average mortality had been 140, but last year it was 91, and this year 86.

Tuberculosis.—Regarding tuberculosis, the lecturer said that it was now universally admitted to be caused by infection with the tubercle bacillus. Other microorganisms might become associated with the tubercle bacillus, and their symptoms might even eventually predominate. Tuberculous diseases of the glands, bones, and joints frequently became arrested without treatment, and the same was true probably in from ten to twenty per cent. of cases of pulmonary tuberculosis, but a natural cure or arrest was, after all, the exception. Nor could we say that after such a cure there was any immunity, for it was well known that people easily contracted tuberculosis a second time.

Tuberculin.—A study of the tuberculous processes in man, in spite of their subacute course, inclined one to approach the treatment by immunizing injections or treatment by antitoxins with considerable scepticism, albeit with some hopefulness. Koch's old tuberculin had now been largely displaced by the new tuberculin. According to Koch, after each injection there was a noticeable improvement in the tuberculous process, and, after several months, all reactions ceased, the patients having become immune to the toxin. Further injections were useless until this immunity had passed off. Many cases of true tuberculosis were claimed to be cured or greatly benefited by several periods of such treatment. The old tuberculin of Koch neutralized the tuberculosis toxins, but was not bactericidal, and consequently Koch had sought to obtain the bactericidal action in the new tuberculin. He had found that the envelope of the tubercle bacillus was so resistant that it could be destroyed only by agents and processes which would render the preparation useless. In the new tuberculin, the bacilli are dried in a vacuum, ground in an agate mortar, placed in distilled water, and centrifugalized. The sediment is then removed, dried, and again ground in a mortar, and mixed with sterilized water. The clear fluid is the pure tuberculin. It could be readily seen, Dr. Park said, that contamination was difficult to avoid by such a method of preparation, and the strength of the solution must vary greatly at different times. As a preservative, twenty per cent. of glycerin was added. It was claimed that, in marked contrast to the old tuberculin, the new tuberculin was strongly immunizing. The initial dose should be one five-hundredth milligram, the proper dilution being made with decinormal salt solution. The dose should be gradually increased, and the remedy given on alternate days. Temperature reactions of only about half a degree had been reported. The full dose of the new tuberculin was twenty milligrams. Unfortunately, only general accounts had been published of Koch's experimental work on animals. In lupus cases, and cases of phthisis, Koch had reported marked improvement in every instance, with no bad symptoms, and all the patients had improved in their general condition and in the physical signs. Koch gave no hope of benefit in advanced cases of tuberculosis, or in cases of pronounced mixed infection. This necessarily excluded a large number of cases seen in ordinary practice. The results from the old tuberculin in this country had been very slight. It was claimed that the new tuberculin not only neutralized the poison, but directly killed the bacilli through the substances produced by the body cells from the tuberculin.

Preparations of Tuberculin.—With regard to the different preparations of tuberculin, it was probably safe to say that there was none better than that made by Koch himself, but the tuberculin sent out by the manufacturers deputed by Koch to make tuberculin did not have the characteristics insisted upon by Koch, but gave every evidence of contamination and varia-

bility. This had been the experience at Dr. Trudeau's sanatorium, where they had also found that when the contents of a vial of the new tuberculin were centrifugalized, not only did many samples contain tubercle bacilli, but these bacilli were alive and capable of causing infection. In this connection, it was worthy of note that two of Koch's animals which were being immunized by tuberculin developed tuberculosis, as a result of the tubercle bacilli injected.

Present Status of Tuberculin Treatment.—Reports from abroad seemed to indicate that lupus showed even more benefit from the new than from the old tuberculin. Regarding phthisis, laryngeal tuberculosis, and other tuberculous processes, no definite opinion was expressed, even by those observers who had used it under specially favorable circumstances. All urged great care in increasing the dose, especially from new vials.

Serum Treatment of Tuberculosis.—Turning to the discussion of the serum treatment of tuberculosis, Dr. Park said that since 1894 attempts had been made to treat tuberculosis in man and animals with serum. The majority of observers claimed the power of neutralizing the effect of tuberculin when injected into tuberculous guinea-pigs, but this test was insufficient, as tuberculin was not the same as the unaltered products of the tubercle bacillus. Moreover, Trudeau had shown that other non-specific substances had the same effect in neutralizing the tuberculin. Very few observers had been able to obtain appreciable effects with serum obtained from different sources.

At the Trudeau sanatorium several patients had insisted upon the serum treatment and had received it. No effect, either good or bad, had been observed in them. Many of the tuberculins on the market now were apparently no better than normal horse serum.

Diseases Due to the Pneumococcus.—Typical lobar pneumonia, as well as certain forms of endocarditis, pericarditis, cerebro-spinal meningitis, etc., are now known to be caused by the pneumococcus. Lobar pneumonia had the peculiar characteristic of frequently terminating suddenly by crisis. This had been supposed to be due to the development of antitoxins in the blood, but there were certain facts which made this view extremely doubtful. For instance, some cases developed a pneumococcus septicæmia at the very time when liberation of these antitoxins was to be expected. Again, the majority of pneumococci died in cultures after five or seven days. It was possible, therefore, that in the lung certain conditions develop which render the solid unsuitable for the further growth of the bacillus or for the development of the toxins. In 1886, A. Fraenkel had begun immunizing-experiments on animals. The serum used in over forty cases of pneumonia in man gave doubtful results; it was apparently neither harmful nor beneficial. Of a number of animals, some could be immunized, while others succumbed. The curative power of the serum was probably very weak. As yet, the serum could not be said to be of practical value in the treatment of pneumococcus infections, and it probably never would be. The serum was, however, practically harmless, so that further experimentation was justifiable.

Streptococcus Infections.—Most of the forms of tonsillitis, erysipelas, cellulitis, and septicæmia were due to streptococci. In none of the streptococcus inflammations had there been noticed much tendency to the development of immunizing substances in the blood. It was true that cases of cellulitis, erysipelas, and abscess, after a period of a few days or months, tended to recovery, so that, to a certain extent, it might be assumed that protective processes had been called forth. Experimentation on man had shown that but little immunizing substance was developed by repeated attacks of erysipelas. Two methods had been used for immunizing and in attempts to establish a curative treatment. One method was to heat to a certain point bouillon cultures of virulent streptococci; in the other method, living and virulent streptococci were themselves injected. Marmorek had given the most attention to this subject. The serum had been found to be very unreliable and to lose its virtue rapidly. Thus, Dr. A. W. Williams, in some experiments carried on at the laboratory of the New York board of health, had found that the contents of a vial which were potent last June exhibited no effect in September. He had obtained directly from Marmorek a vial supposed to contain a very high-grade serum, yet it had lost its power in two months. Other experimenters had noticed the same result as from Marmorek's serum. It could not be said that any of the antistreptococcus serums on the market now were reliable, and certainly all were very variable in their action. In 1895, Marmorek had published ninety-six cases of scarlet fever, four hundred and eleven of erysipelas, and sixteen of puerperal fever treated with his serum. Marked improvement was reported in all of those due to streptococci. Seven of the sixteen cases of puerperal fever were due to streptococci, and in all of these the patients recovered. On the other hand, four cases in which the streptococci were associated with colon bacilli proved fatal. In phthisis, when no cavities had yet appeared, the fever and sweatings diminished under the use of the serum, but no cures were claimed to have been effected. The speaker said that he had seen two cases of puerperal fever in which distinct results had been observed from the use of the serum, but in neither case were any streptococci obtained from the blood. The results obtained here in New York, by both physicians and surgeons, had not been specially favorable. It might be fairly concluded (1) that the preparations of anti-streptococcus serum now on the market are either weak or entirely wanting in curative substances; (2) that we are justified in using the serum only when it has been recently tested and shown to have some value; and (3) that we should, as far as possible, establish the variety of bacteria causing the infection, in every case in which the serum is used.

Treatment of Sarcoma by Erysipelas Toxins.—This subject, Dr. Park said, had received attention in this country chiefly from Dr. W. B. Coley, and consequently the views presented were those of that observer. He found that the inhibitory action of the toxins on carcinoma had proved nearly always to be temporary, and that in no case had the disease after their use remained in abeyance sufficiently long to allow it to be considered cured. In sarcoma, the only form in which he had advocated this treatment, the toxins, when injected subcutaneously into the tumor substance or into more remote parts exercised a distinctly inhibitory action on the growth of the tumor. This was the least marked in the melanotic form. On round-cell sarcoma this action was far more powerful. In a number of cases of round-cell sarcoma, in which the diagnosis was unquestioned, the patients remained well beyond three years. Nearly one-half of all the cases treated showed no appreciable decrease in size; others decreased at first, and then increased. In the spindle-cell variety, the tumor disappeared entirely in half of the cases, and the patients remained well sufficiently long to be regarded as cured. All the cases treated were considered as inoperable. Three cases of spindle-cell sarcoma remained well for three years. One after three years and three months had a recurrence in the abdomen. This, in itself, substantiated the diagnosis. Dr. Park said that it was curious that the largest percentage of successes occurred in the spindle-cell sarcomata—just that variety in which mistakes in diagnosis were prac-

tically impossible. In every case the diagnosis of the clinician had been corroborated by the pathologist before the treatment was begun. In estimating the value of this method, it should be remembered that the treatment was sometimes deleterious to the general health, and that occasionally these sarcomata disappeared spontaneously. Nevertheless, the proof was very strong that some sarcomatous tumors had been arrested and caused to disappear by the treatment. When a sarcoma was inoperable and progressive, he thought the treatment should be tried.

The Plague.—It was now known that the plague was due to a specific bacillus, and that the infection was transmitted, not only by the infected bodies of men, but by rats, insects, and flies. These animals had been thought to be a frequent cause of the dissemination of the disease. A serum which possessed a very fair degree of immunizing power had been obtained from animals. Out of 500 persons immunized with this serum, only 5 contracted the disease, and 3 of these died. In 149 cases of the plague treated with the serum, the mortality was forty-nine per cent., as against eighty per cent. in the untreated cases. In these cases a weak serum had been used which had been hastily prepared by Roux in response to an urgent and unexpected demand. A better serum gave only 2 deaths in 26 cases. Haffkine's treatment had been tried on 1,300 exposed persons, of whom 55 contracted the disease and died. Some immunity seemed to have been produced. Fever and prostration followed the injections, and lasted one or two days.

Typhoid Fever and Cholera.—Animals could be immunized to both typhoid fever and cholera. The serum possessed feeble antitoxic and bactericidal power. There was reason to believe that in a severe epidemic of typhoid fever it would be possible to carry out immunization, although, of course, it would be ordinarily far easier to enforce the well-known prophylactic measures. The curative treatment of typhoid fever with serum had given no marked results, although a few claimed a decided reduction in the duration of the disease.

Hydrophobia.—No specific micro-organism for rabies had yet been discovered in the brain or spinal cord, but it was certain from the phenomena of the disease that one did exist. The preventive treatment of Pasteur had been subjected to much severe criticism, but the speaker believed that to-day its efficacy was firmly established. The reported diminution in the percentage of those developing hydrophobia after bites of rabid animals seemed hard to believe, yet a conservative estimate of the death rate from hydrophobia in those not treated by the Pasteur method was from ten to twenty per cent., as against a little more than one per cent. under the Pasteur treatment. Occasionally, though very rarely, a person developed rabies some weeks after the treatment, when immunity should have been conferred. This had never yet been explained. He believed that hydrophobia had never occurred among the thousands treated at the Pasteur Institute, Paris, as a direct result of the treatment.

The Future Contributions of Bacteriology.—As to the future therapeutic results from bacteriology, the lecturer asserted that the outlook was bright for obtaining through serums, or the toxic substances of the micro-organisms themselves, the means of immunizing against most, if not all, the diseases due to specific micro-organisms. This immunity was not usually of long duration, but could be prolonged by repeated injections. The prospect of securing serums which would promptly arrest the development of diseases already established, by destruction of the micro-organisms and their poisons in the body, was rather less encouraging now than shortly after the discovery by Behring of diphtheria antitoxin. We could hope only to stop all growth of micro-organisms and prevent further action of bacterial poisons at the moment when a case came under treatment. From the fact that substances had been obtained which strongly inhibited certain bacteria, without affecting other bacteria, it seemed probable that we might find chemical substances which would have specific bactericidal power. The expense of experimentation was now very great, as many animals were required, and an additional obstacle to the work of laboratory investigators was found in a lack of co-operation on the part of the clinicians. So far, the work in bacteriology seemed to indicate that our advancement would be rather in the way of preventing disease. At the present time, outside of the diphtheria antitoxin, tetanus antitoxin, and the plague antitoxin, we had no serums which would give practically curative or immunizing results at a time when danger of infection was imminent or infection had already taken place.

National Bureau of Health.—Dr. A. Jacobi said that the New York Academy of Medicine had appointed years ago a committee to frame a bill, and to urge its adoption by the Congress of the United States, favoring the nationalization of the sanitary interests and rules of the whole country. In the past, as at present, the prevention and treatment of contagious diseases, both imported and indigenous, were matters of municipal, county, or State concern. When, a number of years ago, cholera appeared at our doors, the necessity of centralizing national safeguards became evident to every unbiassed mind; when, however, the immediate danger had passed, the democratic instincts, natural enough a century ago when the population was small and communication difficult, of egotistic individualism and jealous territorialism became again superior to legitimate anxiety and the teachings of recent experience. Late occurrences in the Southwest had furnished another proof of the fact that in the actual or alleged dangers of a newly imported contagion, not only the sanitary interests of seventy millions of human beings, but also the commercial necessities of the whole country, were at the mercy of every State government, every county commission, every village supervisor, ay, every mob, both ignorant and criminally reckless. Travel and trade had been stopped, high State affairs interfered with, health officers of the county and of States had been prevented by force from attending to their duties and labors in behalf of public health and hygiene. This was why yellow fever, instead of being stamped out at once, had spread, and disseminated both its actual and insane terrors. Instead of applying the methods of scientific prevention and extermination of yellow fever, the accumulated knowledge of the century pertaining to the care and extinction of contagious scourges was thrown to the winds. That would always be so until the commonwealth of the Union should take the responsibility of caring for the health and life of one and all.

Dr. Jacobi then made the following motion, which was seconded and carried unanimously:

"That the New York Academy of Medicine authorizes its president to call the committee appointed years ago, and never discharged, and direct it to resume its interrupted labors and to report to the Academy of Medicine, for presentation to the Congress of the United States for adoption, the old bill, or a new bill, or to support a proper bill offered by great medical or commercial bodies, contemplating the centralization under the national government of the means to protect efficiently the health of the American people against the importation and dissemination of contagious diseases."

Committee on Public Baths.—This committee, consisting of Drs. S. Baruch, G. B. Fowler, and R. Van

Santvoord, reported through Dr. Baruch that the committee had called on Mayor Strong on the day following the appointment of the committee, and had directed his attention to the fact that there was no longer any good reason for delay in erecting the public baths. The mayor was convinced, and suggested a city lot in Rivington Street as appropriate. Since then plans had been drawn up and bids advertised for, preliminary to the erection of a public bath on this site.

Donations to the Academy from a Layman.—Dr. F. A Castle said that it was not very common to receive donations from the laity, and in view of this fact, and particularly in view of the cordial interest taken in the welfare of the academy by Mr. S. P. Avery, he had thought it but right to bring before the fellows some recent gifts from this gentleman, and to suggest that a suitable acknowledgment of his kindness be made through the secretary. Among other things were an anonymous manuscript on materia medica, dating back to 1792, and a very rare volume, nearly two hundred years old, entitled "The Statutes of the College of Physicians of London."

SECTION ON GENERAL MEDICINE.

Stated Meeting, October 19, 1897.

Louis Faugères Bishop, M.D., Chairman.

Marked Cardiac Hypertrophy and Dilatation; Pertussis.—Dr. Richard C. Newton, of Montclair, presented the heart and lungs removed from a child nine years of age, who had died of consumption. The child had had whooping-cough at the age of five years. The heart showed hypertrophy of the right and dilatation of the left ventricle. The very great thickness of the walls of the right ventricle was worthy of note.

Internal Medicine as a Vocation.—Dr. William Osler, of Johns Hopkins University, Baltimore, read a paper with this title. He said that he wished there was some other term to designate that wide field left after the separation of surgery, midwifery, and gynæcology. Not in itself a specialty, but embracing some half-dozen fields, its cultivators could not be called specialists, but must bear the good old name of "general practitioner." In spite of assertions to the contrary he would maintain that the opportunities for a general practitioner were still great and the harvest was plenty, The laborers, while not a few, were scarcely sufficient to meet the demand. He had often told his students that syphilis was the only disease that they must know thoroughly—if one knew syphilis, one knew internal medicine. His hearers could easily recall the names of great physicians—Swett, Alonzo Clark, Austin Flint, Loomis; their works remained, but the best of a great physician's experience unfortunately died with him.

How to Prepare for Consultation Practice.—Wherewithal should a young man prepare himself if he desired to follow in the footsteps of such a man, for example, as Austin Flint? He would assume that he started with equivalent advantages, though this was taking a great deal for granted, because Austin Flint had a strong bias for medicine and he early fell under the care of such great men as James Jackson and Bigelow. These men had influenced Flint most conspicuously. His well-known address on "The Self-Limitation of Disease" was really a worthy commentary on Bigelow's celebrated essay on this subject.

But to return to the student who had just left the hospital. Should he go abroad? It was not necessary; the man chosen for his exemplar did not find it necessary to do so. Would a trip abroad be useful to him? Undoubtedly, for he would have a broader foundation on which to build. To walk the wards of Guy's or St. Bartholomew's or the Salpêtrière, to put in a few quiet months of study at one of the German university towns, would store the young man's mind with priceless treasures. It was assumed, of course, that he had a mind. If he could not go abroad, let him spend part of his vacation in seeing what was being done in the various medical centres. A New Yorker might learn something at the Massachusetts General Hospital, or in Philadelphia, or even with Welch at the Johns Hopkins Hospital. The successful consulting physician of to-day, it would be found, had evolved either from general practice or from the laboratory and clinical work. Many of the most prominent had risen from the ranks of the general practitioner.

The speaker said that it was his object in this address to speak particularly of the training of men who started out with the object of becoming purely physicians. From the vantage-ground of many years of hard work, Sir Andrew Clark had told him that he had striven ten years for bread, ten years for bread and butter, and twenty years for cakes and ale. A dispensary assistantship should be available, and anything should be acceptable which brought the young medical man in contact with patients; but let him see to it, as he valued his future life, that he was not entangled early in the meshes of specialism. Having become thus established, he could begin his medical education. At the present time he could follow three lines of work—chemistry, physiology, and morbid anatomy. The professional chemist looked askance at the physiological chemist, and *vice versa;* but there could be no doubt about the value to the physician of a thorough training in organic chemistry. In this country men possessed of such training were sorely needed. If at the time of starting our student had not had a good chemical training, the other lines should be more closely followed, because of the very long time required to get a proper knowledge of organic chemistry. Physiology opened a wider view and rendered possible a deeper grasp on the problems of disease. A thorough chemical training and a complete equipment in methods of experimental research were less often met with in a good clinical physician than a good knowledge of morbid anatomy. If he must limit his work, chemistry and physiology should yield to the claims of the deadhouse. In this early period he should see deadhouse work, if possible, daily. It was of special value in diagnosis, enabling him to correct his mistakes, and, if he read his lessons aright, might possibly keep him humble. After a thorough course of this training, it was a good plan to go to a German or French clinic for the summer only, which could be done at a very moderate expense.

The Dry-Bread Stage.—At this stage the young physician should live on the "crumbs," the pickings from men in the "cakes-and-ale stage." Some financial assistance could also be derived from class fees or from journal work. Success in the first ten years meant endurance and perseverance. "All things come to him who has learned to work and labor." In this dry-bread decade the young physician should not despise dispensary work. Many of the best-known men in London had served from fifteen to thirty years in the out-patient department before getting a hospital ward. Dr. Lauder Brunton only got a ward at St. Bartholomew's Hospital two years ago, yet he had been assistant physician and seen cases in the out-patient dispensary for more than twenty years. Dr. Samuel West had been an assistant physician for over twenty years. Dispensary work was of incalculable value in the development of the young physician; it was also of inestimable service in teaching. In this period he should not lose the substance of ultimate success while grasping at the shadow of present opportunity. Time in these years was his money, and he

must not barter away too much of it in profitless work —*i.e.*, in work which would not be of value in his education. Too many excellent clinical physicians had been ruined by spending too much time in journal work, thereby temporarily gaining but losing in the end.

A very serious problem confronted the large schools of this country. He knew of no single physician in this country with wards enough to give his third and fourth year students thorough practical bedside instruction. Therefore, to relieve the extraordinary congestion that must come in the schools, now that there is a four-year course, the younger men must be utilized in two ways, viz.: (1) in the dispensaries in which first-class clinical instruction could be given; and (2) by the adoption of some such method as exists in Edinburgh, of individual clinical instruction by those possessing an equipment and qualifications that met the approval of the authorities of the medical schools. The hospitals could not begin to give the amount of clinical instruction needed.

The Bread-and-Butter Stage.—The young physician would find that ten years of hard work would tell with his colleagues. The second, or "bread-and-butter" period, was more trying to most men, for the risks were greater. At this time many dropped out by the wayside and drifted into specialties. Success came more slowly to the physician than to the surgeon. Some surgeons were in full practice at forty years of age; not so with the physician. The surgeon must have hands, and, better, young hands; he should have a head too, but this seemed not so essential.

The Cakes-and-Ale Stage.—After these years of work our future consultant would probably have but little funds in the bank, but he should have a great stock of interest-bearing funds in his brain marrow. It was not improbable that he might awaken suddenly after twenty years of quiet work, done for the love of it, to find that success was assured. In this State there were probably a score of small hospitals, offering splendid material for good men, on which to build up a reputation. A young man should look for a consultation practice after twenty years of hard work in any town of forty or fifty thousand inhabitants. "Many are called: few are chosen." But even after he had reached the period of "cakes and ale," there were many drawbacks. There were two circles—an intraprofessional and an extraprofessional one. In his efforts to keep up with a trying consultation practice, and at the same time keep abreast with all the new things known to the younger men in the "bread-and-butter stage," the consultant should, indeed, arouse our sincere sympathy. Again, the consultant must walk with the boys, or he would be gradually but inevitably lost. In order to keep his own mind receptive and impressionable, he must travel with physicians between twenty-five and forty years of age. At some time or other there would come the temptation to court the Delilah of the press—lay or medical. It should be ever borne in mind that she was sure to play false in the long run, and that the young physician yielding to her allurements would certainly be shorn of his strength and reputation. It could not be denied that a little humbug succeeded immensely with the public, but it was not necessary. In a certain city were three physicians of such eminence that all present would recognize them if their names were mentioned. The first was a good physician, but no humbug: the second was no physician, but a great humbug: the third was a great physician and a great humbug. The first achieved the greatest success. "Better a handful of quietness than both hands filled with vexation of spirit."

Relation of General Medicine to the Specialties.—Dr. William M. Polk said that, in common with the other members of the academy, he felt much indebted to the distinguished gentleman who had come all this distance in order to give his impressions of the right path to follow to attain success in internal medicine. If that man were not sitting here in person before us, it would not be out of place to draw attention to the great success which he had attained by practically following the line which he had so gracefully sketched out this evening. There was certainly a good deal in the statement made by Dr. Osler concerning the surgeons and the amount of cerebral tissue required by them as compared with that which was essential to the success of those who confined themselves to internal medicine: yet no one could practise medicine in any department—even surgery—unless he had a knowledge of internal medicine. The surgeon took it up where the man of internal medicine left off. The poorest surgeon was he who began work as a surgeon, for the reason that he inevitably magnified his method to the detriment of that of the physician, and in so doing frequently stepped in when his confrère would have been able to carry the case to a successful conclusion. The great good that internal medicine had done was in ridding us of the necessity of taking medicine—in teaching us how, by living and moving, we can escape many of the ills that flesh is heir to.

Legitimate Advertising a Prime Requisite.—Regarding what was the best way of making a good consultant, Dr. Polk said that one of the first things was to know how to write and when to write—in other words, the aspirant for such a position must learn the legitimate method of professional advertising. If this were done, there was not the slightest danger of the young medical man drifting into advertising in the public press. But it should be borne in mind that the two could not be mixed. Another important element in his preparation for this great work had been strenuously insisted upon by the late Dr. Alonzo Clark, viz.: In the early part of one's career two or three cases sifted to the very bottom would teach more to the young and receptive mind than a whole hospital full of cases not so carefully and minutely studied.

Specialism a Curse.—To-day the curse of medicine was specialism. That seemed a broad statement: nevertheless it was a true one, because it was responsible for narrow-minded, poorly educated, and dishonest physicians. By this he meant that the human mind was so constituted that, given any problem to work out, it continued to build upon it and magnify it until oftentimes every other structure, no matter what its importance, was overshadowed. While, therefore, specialism had in many instances done much good, it was to-day demoralizing the profession in large measure by bringing it into contempt with the laity. Many a patient—perhaps honestly on the part of the physician—was made to feel and to believe that conditions which were amply met by many of the ordinary rules of hygiene and living were of such overshadowing importance that they must be attended to there and then, or dire calamity would overtake the individual. This might be the low side of specialism, but it had a low as well as a high side. In the past twenty years, during the rapid growth of specialism, it could not be denied that we had often allowed ourselves to drift into this side of it, which was by no means the highest. No man could be a good specialist who had not been a general practitioner. In this connection the example of the carrier pigeon should be emulated. The carrier pigeon, when loosed to execute a special mission, rose, ever circulating upward and upward, casting its eyes in every direction, so as to get the broadest possible view of the entire field before gathering to itself its strength and making straight for its goal.

Dr. Andrew H. Smith said that he had been particularly interested in the way the two preceding speakers had approached this subject from opposite standpoints. As he had understood Dr. Osler, the student should start out with the idea of making himself a consultant, and in no way to become a family physician. On the other hand, Dr. Polk had an eye to the main chance, and advocated starting out with a view to success in practice. Possibly after all the best would be the happy medium. Certainly all the time mentioned by Dr. Osler would be required in order to reach the goal that he had fixed. In the study of internal medicine it was necessary to take in a considerable knowledge of specialties. What was a man to do who approached a case of renal disease unless he was familiar with the ophthalmoscope? He had only done a part of his work when he had taken the history, noted the symptoms and signs, and examined the urine. Moreover, a careful chemical and microscopical examination of the urine was in itself considered a specialty. In order to become master of so many specialties, it was evident that he must refuse the opportunities for obtaining practice other than that of a consultant. He was reminded of what John Hunter had said when called to a sick person while he was earnestly engaged in the study of some subject. He put off going again and again, until he thought the patient's patience had become exhausted; then he left his work, saying: "I suppose I must go and earn that d—d guinea."

Great Consultants as Scarce as Great Statesmen.—The speaker said that it seemed to him that the great consultants of the future were going to be as scarce as great statesmen were at the present time. At the time that Austin Flint was so prominent as a consultant there were also many prominent statesmen, but they had died out. In medicine there was a multitude of very clever men, but only a few who stood head and shoulders above the rest of the profession. Aside from a special training, there must be some peculiar fitness. Take, for example, Dr. Flint. He could not use the laryngoscope, and probably not the ophthalmoscope; nor did he believe that Flint would have had a person swallow a bucket of water, to have it brought up again and the digestive fluids minutely examined. But Flint possessed certain habits of observation and perception; there was something about him which enabled him to see further into a millstone than others perhaps could see, even with the microscope or by means of the *x*-rays.

Dr. Smith said that he had often been asked by young medical men for advice as to how to shape their career. He had always told them to put themselves in touch with disease in any way that they could, but at the same time to attempt to handle only so much of it as they could attend to thoroughly and exhaustively. He also told them to treat every patient, whether a tramp or a millionaire, with precisely the same care and conscientiousness. This kind of work, continued year after year, without seeking the plaudits of the world in any way, and with the interest of the patient at heart more than one's own aggrandizement, would almost inevitably lead one in the end into a successful business. He thought all would agree that a good specialist must have first been a good practitioner.

A Distinction between a Good Diagnostician and a Good Practitioner.—A very important distinction was that made between a good diagnostician and a good practitioner. It used to be said a few years ago of the French school that its followers wished to make a diagnosis, and that then they were anxious to have the patient die in order that the diagnosis could be confirmed at the post-mortem table. This tendency was often observable among our own consultants. The pathological conditions were often carefully and elaborately explained by consultants, but when it came to treatment we received no further light. The consultant would often ask: "What have you been doing for the patient?" and after hearing the answer of the attending physician would advise him "to continue the same."

The Therapeutic Instinct.—Trousseau used to speak of "the therapeutic instinct." He believed there was something in this. Some consultants would inevitably strike out a nice idea in treatment; others would merely tell you what the patient had, and leave you to find out the best way of securing relief. The therapeutic instinct was often extremely well developed among practitioners in the rural districts, who had been largely thrown on their own resources. He had often been astonished at their fertility of resource—at how often they could "get there," when men much more thoroughly equipped halted by the way.

Internal Medicine Not Now in Public Favor.—Dr. A. Jacobi said that the chairman had asked to hear from those who wished to speak on the question, and had called on him. He did not wish to speak on the subject, and came entirely unprepared except what he might have gathered from a practice of forty years in this city. Perhaps when he had practised for sixty years he might be able to say something. He would accordingly make only a few commonplace remarks.

Dr. Smith had already pointed out that Dr. Osler had spoken of a particular class of men practising only internal medicine. This class was a very small one. But there was a very large class, to which he himself belonged, who had made internal medicine their vocation. This class of practitioners had lost ground in the last twenty years, in favor of the specialist of all degrees—particularly the lowest degree alluded to by Dr. Polk. Internal medicine had certainly lost ground with the public. The physician, by many months of careful study, might diagnosticate a tumor and its location, but this counted for little with the laity. When, however, the surgeon came and removed it, the people said: "What a brilliant operation!" and in many instances they might have added very pertinently: "Did he run off with the physician's fee?" At the present time, if a woman had a headache, she must needs have a neurologist; if she had a pain about the chest—it might be a pleurisy—she would go to a neurologist; if she had pain around the eye, she would seek advice from the ophthalmologist: if the pain were in the foot, she might perhaps go to the chiropodist. The nose must be blown by a rhinologist. The laryngologist now took away from the general practitioner even the cases of catarrhal croup. Then there was the abdominal surgeon and the appendicitis man, the stomach specialist and the hemorrhoidal specialist. There appeared to be nothing left for the general practitioner; it appeared, in fact, that the vocation of internal medicine had gone. Still, it had not really gone. He had been a general practitioner for many years, and expected to die a general practitioner. He was perfectly satisfied with his position. Many had become specialists because they did not know anything about general medicine.

The Sacred Position of the Family Physician.—To him internal medicine as a vocation was a sacred position in life. Such a practitioner not only had to deal with every organ of those who confided in him, but he was expected to know a great deal about their persons and their past—he knew not only their lives, but their hearts. It was his duty to look out not only for present diseases, but for such diseases as might develop—in other words, he was the hygienist of the family. If one wanted a good sanitarian, one must look for him, not among the surgeons, the laryngologists, or even the bacteriologists, but among the well and broadly educated practitioners of internal medicine. If the duties and the rights and the accomplish-

ments of the general practitioner were compared with the dexterity of the most eminent specialist, it would be found that there was more influence, private and public, associated with the achievements of the general practitioners. Internal medicine, as a vocation, was really the complex—the one-in-all of general medicine.

The Fame of Physicians Outlives that of Surgeons.—We spoke of the great physicians of olden times and all the way down to modern times. All the great names mentioned this evening were of those who had made internal medicine their vocation—Austin Flint, Alonzo Clark, Mitchell, Physick, and others—every one a general practitioner. The surgeons of their times had almost disappeared from the history of medicine, and certainly from the history of mankind and from the memory of the profession. Specialism, with the features characterized by Dr. Polk, was now about at its height—not at the top of the ladder, however. It would certainly be remodelled, and we would have in the future fewer-but better specialists. Whatever was good and useful for the common weal would have to be looked for in internal medicine, which would then be the vocation of the profession.

In closing, Dr. Jacobi quoted the words of a good specialist in this city: "The internal practitioner, the general practitioner, is the statesman of the profession;" and added: "So it is, and so it will be."

Dr. Osler, in closing the discussion, said that he hoped he had not been misunderstood as reflecting too strongly on the surgeons; he had intended to say only what was well known, that success to the surgeon came earlier than to the physician, and it was more a matter of the heart than of the head. He saw no reason why, in our large cities, the younger men who looked forward to having a hospital ward should not do some general medical practice, but they should look forward to building their reputation chiefly on their work in the dispensary and hospitals. He was quite sure that the method used in London had proved very successful. Some of the brightest and most successful medical men had not been in general practice, but had developed directly from dispensary and hospital work. There was no reason why the young medical man, in his first few years, should not learn the mere technical use of the laryngoscope and of the ophthalmoscope: indeed, some of this knowledge was now acquired in the senior year at the medical school.

The Consultant Must Keep Young.—He was sure if Dr. Flint did not know much about bacteriology he always took care to have around him young men who did. The great feature of Dr. Flint was that he retained to the last a great deal of receptivity; he had less lime salts in the cells of his cortex than any other man of his age whom he had met. He was young to the end, and apparently because he kept young men always about him.

The Diagnosis All-Important.—In a large proportion of cases, he thought, the only important function of the consultant was to establish the diagnosis. The last three cases that he had seen in twenty-four hours illustrated this very well. One man was dying of pernicious anæmia, because it had not been recognized, and he was being treated for malaria. The diagnosis would certainly prolong his life, to say the least. In the second case the diagnosis was not of importance, as it happened to be a cancer of the stomach. In the third case the diagnosis might or might not save the woman's life—it depended upon the surgeon. She had a stone in the common duct. Hundreds of dollars had been uselessly expended on her for medicine, all for the lack of a correct diagnosis. One sad feature about the life of the consultant was that he came often as a *nunc dimittus*—as simply the one who preceded the undertaker.

A Brighter Future for Internal Medicine. — Dr. Osler said that he thought the position of internal medicine would become better and better in this country, because the younger men would in greater numbers devote themselves to internal medicine in the broader sense of that term. After all, as Dr. Jacobi had said, the chief prizes of the profession did not fall into the hands of the specialist, but into the hands of men who had passed through many years of faithful and unremitting toil.

Vote of Thanks.—On motion of Dr. Polk, the academy tendered Dr. Osler a vote of thanks for the eloquent paper that he had so kindly presented.

SECTION ON SURGERY.

Stated Meeting, October 11, 1897.

B. Farquhar Curtis, M.D., in the Chair.

Intra-Uterine Fracture Complicated with Congenital Absence of the Toes and Metatarsal Bones.—Dr. A. M. Phelps exhibited an infant with this condition. At the sixth month of intra-uterine life the mother while in a street car had been injured by a heavy woman falling upon her. She gave birth to the child at full term, after a dry labor. It was then discovered that the infant's tibia and fibula midway between the knee and ankle were bent at a right angle, the sole of the foot looking directly backward. There was also an absence of three of the toes. The child had been brought to him when it was four months old, and he had advised postponing operation until the age of nine months. He had then operated, cutting down upon the point of fracture. He was able to demonstrate that it was indeed a fracture, because the upper fragment overlapped the lower, the latter being joined at right angles to the upper. A sufficient amount of bone was cut away to allow the foot to be placed in the normal position. Radiographs of the condition were presented, and they illustrated the points brought out. Photographs of the case before operation were also shown. At the present time there was a shortening both of the femur and of the tibia and fibula, of about three inches. The points of interest were these: (1) An intra-uterine fracture occurring with a congenital deformity of the foot; (2) the importance of the operation which was performed, as it placed the foot in such a position as allowed the foot-bearing socket for an artificial limb to be worn with great comfort; (3) it might also permit the limb to grow. An amputation at any time before adult life would very probably result in a conical stump, and if the foot and limb were left in their original position there might result extreme non-development with great shortening.

Chronic Hydrocele with Calcification of the Sac.—Dr. B. Farquhar Curtis presented a man, forty-one years of age, a native of Nassau, who for over twenty years had had what had been supposed to be a tumor of the testicle. Nothing was done in the way of treatment, as it was neither painful nor a source of great discomfort. On his admission to the hospital there was a tumor occupying the left side of the scrotum. It had a smooth hard surface, and the testicle could not be felt. Very firm pressure gave one the impression that the tumor was cystic. The test with light was negative. At first it was thought that a hydrocele could be excluded on account of the absence of translucency, yet the tumor had the shape and form of a chronic hydrocele in which the sac had become greatly thickened. The latter condition, of course, would explain the absence of translucency. At one examination an "egg-shell crackling" was obtained. At the operation the knife could not be made to penetrate the

mass. The cord was healthy, and, as the testicle could not be found anywhere, it was thought best to remove the whole mass. This was done, and then examination showed the condition to be a chronic hydrocele with an unusual amount of calcification. There was no history of tapping or anything else which would be likely to cause calcification. The entire sac had been converted into a firm shell. The sac contained a fluid very much like pea-soup in appearance, but examination showed it to be a mixture of cholesterin crystals with some fatty detritus. On the inner surface were some rounded masses, evidently due to some hæmatoceles that had formed there. The testicle lay at the back of the sac, and the latter was so distended that it had pushed down the epididymis quite flat. The operation had been done on September 30th, and the patient had made a good recovery.

Mammary Carcinoma; Operation by Meyer's Method.—Dr. Franz J. A. Torek presented a patient from whom a carcinoma of the mamma had been removed by Meyer's method of operating. It had been objected, he said, that this method was very mutilating, and was unnecessarily severe in many cases. An examination of his patient would, he thought, refute the statement that the operation was a mutilating one, notwithstanding the fact that the operation wound was very extensive; *i.e.*, its upper boundary was the clavicle, the inner boundary the sternum, the lower boundary the lower portion of the pectoral, and the posterior and outer boundary the latissimus dorsi muscle. Even by careful tests it was difficult to detect any distinct loss of function; even the adduction of the arm posteriorly was perfectly well carried out by the anterior and posterior fibres of the deltoid. This patient got up on the seventh day; the wound was entirely healed at that time, and she was discharged from the hospital on the fourteenth day. It would be observed that the tumor in the breast was comparatively small. About an inch and a half from the sternum and under the clavicle there had been a minute carcinomatous gland which no one could have possibly detected and removed except by this radical method. This in itself was a sufficient justification of this plan of operating. He had frequently found the glands infected under the pectoralis major muscle, and on this account believed that carcinoma of the breast should be removed by this method, and that we should not individualize and select other operations for certain cases. According to his experience, motion was better when the pectoral muscles were entirely removed than when they were cut through and united again, owing to the fact that when they were operated upon by the latter method there was more downward traction. The tumor had first been noticed by the patient last April, and the operation had been done on September 3d.

Amputation of Shoulder-Joint for Carcinoma; Skiagraphs.—Dr. Arthur L. Fiske presented a man, thirty-nine years of age, who had entered his service at the Cancer Hospital on August 30th. The family and personal records were good. Last January the man had first experienced a slight pain in the shoulder, and this had gradually become more severe. In the early part of June a swelling had been noticed about the shoulder, accompanied by more or less disability. There was no history of any injury. The clinical diagnosis was subperiosteal sarcoma. On September 11th, the shoulder was removed. This case illustrated well the value of skiagraphy in the diagnosis of such conditions. The skiagraph exhibited showed the difference in density between the tumor itself and the muscle mass about the shoulder. In carrying out the amputation a long incision had been made over the head of the bone in order to explore the tumor. It had been found to extend up into the region of the scapula. The vessels having been ligated through the incision, a circular amputation had been done, and the end of the clavicle and the glenoid cavity of the scapula removed. The pathological diagnosis of the tumor was a sarcoma undergoing myxomatous degeneration. The patient had had for a considerable time a good deal of cough and expectoration, and in the sputum numerous tubercle bacilli had been found.

Volvulus with Enormous Distention of Bowel.—Dr. Howard Lilienthal exhibited a man, forty-six years of age, who had been admitted to the Mount Sinai Hospital last August, with a diagnosis of appendicitis. He had been sick for two days, and constipated for a long time previously. The constipation at the beginning of the attack had really amounted to obstipation. On admission he had a temperature of over 101° F.; there was slight icterus; the face was anxious; the pulse was 100 and of good quality, yet the extremities were cold. There was an intensely painful point on the right side, but it was somewhat removed from the location of the appendix. There was also general abdominal tenderness, with so much distention that the speaker had been inclined to suspect general peritonitis. The patient was at once put under chloroform, and the usual incision was made for appendicitis. This exposed a very dark mass, which was tympanitic on percussion. Only on close examination was it possible to discern the striations characteristic of the large intestine. A very large coil of intestine was, with difficulty, removed after enlarging the incision. Actual inspection showed the cæcum and ascending colon to be in their normal positions. The direction of the fibres indicated that the condition was probably a volvulus of the cæcum, and this proved to be the case. The volvulus was readily reduced, but still there was no effort at evacuation. With a rather large trocar it was punctured at the upper part, and a considerable quantity of gas evacuated. Notwithstanding this it was still impossible to replace the intestine, so he deliberately made an incision, one inch long, into it. This gave vent to an enormous quantity of fæcal material. Although he did not expect the patient to recover, the operation was completed, the openings in the bowel being carefully closed with sutures. A packing was inserted down to these points, and the intestine stitched there to the abdominal wall. Strangely enough, the patient had made a perfectly smooth recovery, and the bowels had been easily kept open from the day after the operation.

Dr. B. F. Curtis said, with reference to Dr. Phelps' case, that there was a clear history of fracture, and the bone also showed it clearly. He thought that Dr. Phelps' theory that this was entirely independent of the condition of the toes must be accepted as correct.

Dr. Lilienthal asked what was the theory on which the calcification in the hydrocele case was to be explained. There was no evidence of tuberculosis, and the patient did not have atheromatous arteries.

Dr. Robert T. Morris said that if the tension had been sufficiently great to cause fatty degeneration of the endothelium, the neutral fat might have become absorbed and the fatty salts replaced by calcareous salts. It would be necessary, however, to account first for the fatty degeneration of the endothelial cells. Such a degeneration might arise from excessive pressure, probably from an acute necrosis.

Dr. Curtis said that he was inclined to attribute the calcification to the same causes as those which give rise to calcification of the spleen. The case was certainly a very rare one.

Dr. C. N. Dowd, referring to Dr. Torek's case, spoke of the advantage of the routine removal of the pectoral muscles in cases in which there was a clear

diagnosis of carcinoma of the breast. There had been a remarkable improvement, he said, in the statistics of breast amputations in proportion as the very radical method of operating had become more generally accepted. The mutilating effects were certainly not so great as had been at first supposed. He had himself operated at least twenty times, and all of these patients had had good use of the arm, and in some of them the functional result had been remarkably good, the patient being able to do considerable manual labor. The danger of amputation of the breast had not been especially increased by the more radical method of operating.

Dr. Fiske was inclined to favor a higher incision even than that used by Meyer, for there had been less subsequent œdema and binding down in the axilla in cases in which the higher incision had been used.

Dr. Torek said that in the case presented he had used an S-shaped incision, and had found it a very convenient one. He also liked the high incision, and the straighter it was made, the less would be the difficulty experienced in operating. It was his own practice, however, not to adopt any conventional method of making the incision, preferring to shape it to suit the individual case.

Dr. Curtis said that he felt that the operation was too severe for mild cases, although he hesitated to say so, in view of the improvement in the statistics since the more radical method had been adopted. But we should not allow ourselves to be misled. According to his experience, the tendency had been for the recurrence to take place in the skin, and hence he was inclined to sacrifice more and more of the integument. In the case presented, it was true the tumor was a small one, yet the case was undoubtedly severe, as shown by the extensive involvement of the glands. It seemed to him that in the average case it was illogical to cut away the muscle extensively, when it was impossible to cut very much beyond the disease in the glands. He had been one of the first surgeons in this city to operate by Heidenhain's method. The case was one of recurrent carcinoma. A year later the patient had returned with a carcinoma in the opposite breast. The entire muscle on that side had also been removed, and when the patient was last heard from, three years afterward, there had been no further recurrence. Although the functional result in these cases seemed to be good, it could not be denied that there was a decided loss of power. This could be best observed by causing the patient to keep the elbows close to the side, at the same time separating the hands widely, and by testing the patient's power to squeeze one's hand.

Dr. J. A. Wyeth said that he believed with Dr. Torek that in dealing with malignant growths we could scarcely go wrong in adopting a wide and free extirpation. A good deal depended upon the length of time the neoplasm had been present, upon what part of the mammary gland it had primarily involved, and upon how extensive were the adhesions of the mammary and pectoral fasciæ. When the upper part of the breast was first involved, it seemed to him that a wide extirpation should be done in every instance; it should also be done in those cases in which there was a reasonable doubt on this point. In a certain proportion of cases—and that proportion was increasing, because people were coming earlier for operation—in which there was a limited area of invasion in the lower and outer quadrant, the removal of the pectoralis major or its clavicular fibres was not essential. He removed a part, or nearly all of the sternal and costal portions of the pectoralis major, and was particular to take away all of the pectoralis minor. It was a clinical fact that the lymphatics of the pectoralis minor were most frequently engorged with the metastases. In almost all cases it was necessary to remove the axillary contents from above downward.

Dr. Torek said that he had become firmly convinced by experience of the advisability of removing the pectoral muscles. In cases apparently much milder than the one just presented by him, he had found repeatedly an infection of the glands under the pectoralis minor at a point where it would have been impossible to detect it except by this method of operating. He had not intended to lay much stress upon removal of the muscle, but this course enabled him to extirpate the visibly diseased tissues—the small glands underneath the muscles.

Dr. Wyeth, referring to Dr. Fiske's case, said that so far as he knew, there was not a successful case on record of an operation like the amputation of the shoulder just described by Dr. Fiske. He had himself done two of these operations, and both cases had terminated fatally within six months.

Dr. A. M. Phelps said that about five years ago he had operated in a case of sarcoma. The microscopist had been in doubt as to whether the case was one of pure sarcoma or of fibro-sarcoma, but from the fact that recurrence took place it was undoubtedly a pure sarcoma. It began in the glenoid cavity and involved the scapula more than the humerus. At the time of the operation there was no involvement of the humerus. He extirpated the scapula and saved the arm. A year and a half later the disease recurred in the head of the humerus. He then removed the humerus. At the present time the man was alive and well—two years since the second operation. After the removal of the scapula the man had had a traumatic empyema which had ruptured into the wound in two weeks, and after this had discharged for three or four weeks recovery had taken place.

Dr. Fiske said that he had removed a sarcoma of the shaft of the humerus on January 1, 1897. He had seen the woman in the middle of last July, and up to that time there had been no recurrence. A photograph of this subject was exhibited.

Dr. Wyeth said that he had presented to this section two years and a half ago an enormous osteo-sarcoma involving the head of the humerus. He tied the subclavian artery under cocaine anæsthesia, in the third surgical division, in order to arrest hemorrhage occurring during an exploration that he had made. He had afterward cut off the bone at the shoulder-joint, and presented the patient to the section while the wound was still an open one. This man was inoculated three times with erysipelas toxins, and was now well and strong, and he was beginning to think that the recovery was due to the erysipelas inoculations.

Dr. Curtis referred to the case of a young girl who had had a small tumor involving only the acromial end of the scapula, but so situated as to require the removal of the entire upper extremity. This he had done in September, 1896, and she had made a good recovery from the operation. However, recurrence took place in the scar very shortly afterward, and the girl died in the course of about three months.

Dr. Phelps thought the age of the patient and the character of the tumor had much to do with the matter of recurrence. His patient had been about thirty-eight years of age. In younger persons osteo-sarcoma was usually much more malignant.

Dr. Torek asked if any one had had a case of apoplexy and death occurring after amputation of the shoulder-joint. He had performed such an amputation on one patient, and she had done well up to the sixth day, when she had suddenly been attacked with apoplexy and died. In another case of carcinoma of the neck, in which an extensive operation had been required, an apoplexy had occurred on the

third day after the operation, and death had taken place about two months later.

Dr. George E. Brewer, speaking of Dr. Lilienthal's case of volvulus, said that the distention of the bowel had been something enormous; the mass was certainly as large as a man's thigh. From what he had seen of this case he had felt that it would have been utterly impossible for anybody to make a correct diagnosis before the operation.

Dr. Morris inquired as to where the bowel had been sutured to the abdominal wall after the operation.

Dr. Lilienthal replied that he had made it fast to the abdominal parietes by a suture above and below.

Dr. Morris said that a German surgeon had published a method of preventing the recurrence of volvulus by suturing the entire affected part to the peritoneum of the abdominal wall.

Dr. Lilienthal said that in his case the volvulus had been altogether too large to sew in this manner to the wound.

Dr. Wyeth said of the plan of suturing to the abdominal wall, that a suspicious point in the line of suture was an important part in the technique of intestinal surgery which was too often neglected, and which was not infrequently responsible for the fatal result.

Strangulated Hernia; Extensive Intestinal Resection; Recovery.—Dr. Thomas H. Manley presented a specimen of intestine that had been removed from a young Chinaman who had developed a strangulation of the bowel. No medical aid had been sought for four days, and there had then been enormous distention of the abdomen, a temperature of 103.5° F., incessant vomiting, and a feeble pulse of 130. The point of strangulation in the hernia was found in the usual situation, and the intestine was found to be perforated in several places and completely divided at one point. In this case he had used a running Lembert suture and had made a lateral intestinal anastomosis. The wound had been left open in the manner which had been so wisely insisted upon by the preceding speaker, and he believed that it was owing to this fact that his patient had recovered. The portion removed measured twenty-eight inches.

Dr. Morris said regarding this matter of leaving an open wound at a suspicious point that it was dangerous teaching, albeit safe enough practice in the hands of a surgeon of judgment and experience. Such a method always left a weak point, and exposed the patient to the danger of fistula.

Dr. Lilienthal said that, while no doubt leaving the wound open prevented one from obtaining an ideal surgical result, it would often be found a means of saving life, and certainly the danger of a fistula was a slight one compared with danger to life.

Epispadias.—1. A perineal fistula, made by cutting from the outside, upon the finger introduced into the bladder above to distend the perineum or by the use of Watson's perineal drainage tube. The subsequent steps may be proceeded with at once or ten days after, when time and rest have allowed drying and healing of excoriations. 2. Dissecting up the urethra, which lies open upon the upper surface of the perineum. 3. Separation by blunt dissection of the loosely connected cavernous bodies. 4. The urethra, laid in the gutter then formed, is secured by two sutures through the lower floor of the urethra and skin of the under surface of the penis. 5. The free edges of the urethra are united with continuous catgut ligature over a silver catheter extending to the bladder. 6. The cavernous bodies are then united with continuous catgut, and the skin, which is usually abundant, with interrupted silkworm gut.—Cantwell, *Annals of Surgery*.

THE MEDICAL COUNCIL: CLAIMS OF THE CANDIDATES: PERSONAL NOTES—OPENING OF THE SCHOOLS; THE LECTURES—DR. MANSON, DR. GOW, DR. PYE-SMITH, SIR J. CRICHTON-BROWNE, DR. CARTER—TYPHOID EPIDEMIC AT MAIDSTONE—SIR SAMUEL WILKS, BART. —DEATH OF CAMBRIDGE PROFESSOR.

London, October 5, 1897.

The contest for the medical council is producing a fine crop of electioneering circulars, to say nothing of the meetings, which have attracted larger numbers than was expected. If the excitement continues to increase until Monday, we shall redeem the profession from its apathy. But this interest in the election may affect only the larger centres. It is impossible to gauge the effect of the many circulars on the scattered country practitioners. If they rally around their own order they can easily elect either Dr. Diver or Dr. Rigby, and either would be efficient as a councillor. But if, as I think likely, they do not consider general practice in the country the chief qualification, the contest will lie between Mr. Victor Horsley, F.R.S., and Sir Walter Foster. Those who think we should be represented by a man of the highest repute must support Mr. Horsley, whose fame as a surgeon is supplemented by his position in science, for he grasped its blue ribbon at an unusually early age. Sir Walter Foster calls himself a provincial physician, but his opponents say that as a political man with a residence in London this is only an electioneering pretence. He is consulting physician to the Birmingham Hospital, where he was on the active staff for many years and discharged its duties satisfactorily. His little manual on the sphygmograph (1866) is being again talked of, though not in a way to gratify him; for he gave a sitting to an interviewer and photos of himself in his consulting-room, with the instrument prominent as well as a post card from Mr. Gladstone congratulating him on his skill. The paper containing the interview was produced at a meeting in his support, when he excused it on the ground that as a member of Parliament the public desired information about him, and complained that the matter was sprung upon him without notice, at which some of his supporters affected indignation but others were evidently rather shocked, while his opponents chuckled.

But it is as a medical politician that Sir Walter is best known. He has served ten years in the council, having first been nominated by the British Medical Association, but that in a manner which was condemned at the time and has caused him to bear the burden ever since of being regarded as the tool of the then ruling clique.

But Victor Horsley is also a medical politician, and bids fair to take a place in this respect such as that of the late Mr. Rivington.

The midwives question is the one which is most prominent at the present time and which agitates all ranks of the profession. On this Sir W. Foster in the council and in Parliament has proved weak-kneed and is largely regarded as a dangerous or unsatisfactory representative. Yet to the amazement of many he has secured the support of Dr. Rentoul, the most energetic opponent of the midwives bills, which Sir Walter supported. Mr. Horsley is much sounder on this question; he is opposed to any legislation upon it which does not place midwives under the absolute control of registered practitioners. Moreover he advocates reform of the council, amendment of the acts, and suppression of illegal practices. This is an attractive

programme, and as to the last item his experience as the moving spirit of the Defence Union would be of great service.

The medical schools opened with the month in the usual manner, though defections from the ancient custom of introductory addresses continue. Consequently *conversazioni* and other reunions are gradually supplanting the more time-honored opening. These latter, too, have a more limited interest, each school caring little how the others celebrate the occasion. This year, too, the interest in the opening day has been overshadowed by the election. The addresses, however, were quite equal to the average.

At St. George's Hospital Dr. Patrick Manson urged the importance of a study of tropical diseases. The hospital has lately secured his services as a lecturer on this subject, one on which his experience in the East eminently qualifies him. Dr. Manson's work on the filariais universally known, and his writings on this and cognate subjects are always regarded with interest. He is now physician to the Seamen's Hospital and medical adviser to the Colonial Office. He had long service in the East as medical officer of Her Majesty's consulates (China, Amoy, Takao, Kowloon, etc.).

At King's College the address was given by the new principal, Dr. Archibald Robertson, who succeeds Dr. Wace. The lecturer lamented the "hope deferred" of a teaching university for London, though he thought the injury to the higher general culture by the present state of things did not so much affect medical education as might be supposed.

Dr. William John Gow gave the address at St. Mary's Hospital. He is the assistant obstetrician there and distinguished himself at the London University. He was not educated at this school but at "Bart's." His position will improve if he remains, but St. Mary's has recently been negligent of her sons and this has given rise to many speculations about her system of appointments, once so lauded, but this year leading to the loss of three men who had spent years in her service. Dr. Gow gave excellent practical advice to the students and displayed therein much "common sense"—an admirable quality which he recommended them to cultivate.

Dr. Pye-Smith, now the senior physician at Guy's, went to Sheffield to give the address, and Sir J. Crichton-Browne to Birmingham. *Per contra*, provincial gentlemen came to London's opening day. Dr. Carter, of Liverpool, addressed the students of Charing Cross and the principal of Mansfield College, Oxford (Rev. Dr. Fairbairn), those of St. Thomas' Hospital.

The epidemic of typhoid at Maidstone has gone on extending its ravages all the week, though with varying degrees of advance. Some days over sixty new cases were added to the roll. Yesterday there were twenty-eight, making the total attacks one thousand four hundred and fifty-seven. Visitors to the town have also carried infection to other places and caused considerable alarm, but they are easily isolated—a very different thing from a polluted water supply. The supply from the infected spring has been stopped, but why this step was so long delayed remains to be ascertained. It is widely asserted that the company was reluctant on account of the cost, but surely it could have cut off that spring for the period that the bacilli can live in water, and a dreadful responsibility has been incurred by not having done so. It is stated to-day that Dr. Semple has gone from Netley to offer a vaccine with which experiments have been made at that army school, where he is assistant professor of pathology.

The president of the College of Physicians, Sir Samuel Wilks, baronet, has always been regarded with the greatest esteem, and on Wednesday about two hundred and sixty of his friends and pupils honored him by a dinner. In replying to the toast of the evening he gave some extremely interesting remarks on his own career. He has been known to be exceedingly modest and destitute of any self-assertion. Now he tells us that as a child he was shy—so much so as to be a misery to himself and those about him. At school his master said he needed a spur and all his life he has found he wanted a spur. Let alone, he initiated nothing, having no ambitions. He had fallen into his appointments and supposed he had been fit for them. He had fallen into several posts in his life and accepted the last and highest reluctantly. That was his outer professional life he said, but every one had an inner one known only to himself. He had had troubles which brought headaches, want of sleep, and all that made a man the victim of his organization. He had never courted reputation or cared a straw for public opinion. The only thing he cared for was the respect of his medical brethren, so he had the greatest satisfaction in having his present position thrust upon him. He said a good deal more, but as illustrating the man I need only quote a remark that as far as he knew only three Samuels were famous, viz., the prophet, Dr. Johnson, and Mr. Weller, Jr.

Dr. C. S. Roy, F.R.S., professor of pathology at Cambridge University, died on Monday, and his funeral is to-day. He was only forty-three years old, and had been ailing some two years. He had been director of the Brown Institution, and had worked there and on the continent before being appointed to Cambridge. His most important researches were those on the heart, but he also invented a number of physiological instruments, and he gave a great impetus to scientific work in his department and enlisted a number of students in the great work of research. There will scarcely be a vacancy in the chair, as some time ago, in consequence of his ill-health, Dr. Kanthack was appointed assistant professor and has discharged its duties.

OUR PARIS LETTER.

(From our Special Correspondent.)

DECLARATION OF EPIDEMIC DISEASES—TRANSPORTATION OF PATIENTS WITH INFECTIOUS DISEASES IN PUBLIC CONVEYANCES—THE NEW BUILDINGS AT THE SORBONNE—HYDROPHOBIA—THE FACULTY OF MEDICINE, ETC.

PARIS, October 11, 1897.

THERE is nothing that touches the public health so closely as the spread of epidemic diseases. The French authorities have laid down explicit rules in conformity with the law regulating the declaration of contagious disease in the colonies. Those as actually applied in Paris are now claiming attention. Differing somewhat as to detail from those in force in the colonies, they are as follows:

"ARTICLE 15. Every doctor, health officer, and midwife is held to declare to the public authority, as soon as his or her diagnosis is established, the following epidemic diseases that may come under observation: typhoid fever, exanthematic typhus, variola or varioloid, scarlatina (scarlet fever), diphtheria (croup and membranous angina), suette miliare, cholera and choleriform diseases, plague, yellow fever, dysentery, puerperal affections (when professional secrecy with reference to pregnancy has not been demanded), and ophthalmia of the new-born.

"ARTICLE 21. The doctor of medicine or health officer who does not make the declaration prescribed by article 15 shall be punished by a fine of from fifty to two hundred francs."

It will be seen that the list of epidemic and contagious diseases, while embracing suette miliare or sudor Anglicus, a comparatively rare disease, omits measles, mumps, whooping-cough, and erysipelas,

which, of almost daily occurrence, are not only contagious and infectious but epidemic as well.

The nature of the disease being determined and the declaration made, a question of perhaps even greater importance at once presents itself. It is this: The transportation of patients affected with contagious diseases to the hospital. This, of course, should be done in wagons or ambulances specially designed and set apart for such service, made in such a manner that they can be hermetically closed and thoroughly disinfected by means of formaldehyde or sulphurous gas after each trip. The public health authorities in Paris, appreciating the fact that such patients leave behind them the germs of infection for other passengers that may come after them when they are transported in public carriages, tramways, or omnibuses, have instituted a special service of this kind. Nevertheless such patients are still sometimes transported in ordinary hired carriages. These should never be allowed to return without having first been disinfected with an atomized solution of sublimate. At the Aubervilliers Hospital they give the coachman an indemnity for the time lost by the disinfection. There ought also to be a law enacted, as none, I believe, now exists in Paris, against persons aware of their condition using public carriages for transport. Such an act exists in London, and its violation is punishable by a fine up to £40. In case of urgency the occupant must notify the coachman and indemnify him, he himself being subject to a like fine if he does not immediately after have his vehicle disinfected.

Speaking of public health, some very interesting special health manœuvres for the military government of Paris will take place on October 12th and continue to the 16th. They consist of conferences to be held at the Bellechasse barracks and the docks of the sanitary service department, followed by mobilization and departure of the sanitary corps for Sartory. During the manœuvres there will be a march and fight of a division between Versailles and Velizy. The battlefield will be illuminated and the wounded sought for during the night; there will be a sanitary-service exercise or drill after the combat, with functioning of the hospital of evacuation at the des Matelos station, the ambulance leaving on the 16th, when there will be a *résumé* of the operations.

The old buildings of the Sorbonne, which those who have passed their doctorate at Paris will remember, are about to disappear; in fact workmen have already begun the work of demolition. At the same time the new buildings are being rapidly put into condition and furnished. On the 5th of November the amphitheatre of anatomy and the library will be ready for use. The ceiling of the latter is by William Dubufe and was in the last salon of the Champs de Mars. These changes will take place without any special ceremony and the new buildings will be occupied, a few rooms at a time, as the work of finishing up and installation progresses.

A fatal case of hydrophobia has just occurred, in which it was at first supposed that some insignificant scratch on the hand of the young girl who died had unconsciously come into contact with some object contaminated by the saliva of a dog. It turned out, however, upon investigation that she actually had been bitten about a month ago. The bite, however, was very slight, and as the dog showed no symptoms of hydrophobia no attention was paid to it. The animal had evidently been previously bitten by a mad dog, and was thus in a condition to give hydrophobia before the disease developed in him. This explanation accords fully with the uncertainty existing as regards the incubation period of hydrophobia, which is always long, sometimes extraordinarily so.

Professor Raymond has issued the second series of his "leçons" on "Diseases of the Nervous System," held at the Salpêtrière. It is a volume of the same size and scientific comprehension as the first. It is done in the author's masterly style and is a continuation of what is the greatest work on diseases of the nervous system of our day. Professor Raymond will shortly resume his work at the Salpêtrière for the winter.

The Faculty of Medicine has just published the regular programme and regulations regarding inscriptions, student cards, *travaux pratiques*, etc. An innovation is the following, taken from the text of the regulations: "Those students who may desire the card with photograph will have the photograph pasted on the back of the card, which they will subsequently present at window No. 4, on Mondays and Tuesdays from twelve to three o'clock, for affixation of the seal of the faculty." This detail is not without its importance, and will not only prevent the loan or exchange of cards but will also serve as a means of positive identification.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 23, 1897:

	Cases.	Deaths.
Tuberculosis	196	116
Typhoid fever	32	17
Scarlet fever	98	8
Cerebro-spinal meningitis	0	4
Measles	104	4
Diphtheria	144	16
Laryngeal diphtheria (croup)	2	1
Chicken-pox	11	0

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended October 23, 1897:

		Cases.	Deaths.
YELLOW FEVER—UNITED STATES.			
Alabama, Mobile	October 21st to 22d	49	7

EXPERIMENTS ON URINARY TOXICITY.

BY MARY PUTNAM JACOBI, M.D.,

AND

MARY MITCHELL RYDD, M.D.,

TEN years ago Bouchard remarked: "In certain cases of albuminuria, the innocuity of the urine is remarkable; the kidneys seem to have separated the toxic substances from the urine, keeping them within the organism."[1]

In thirteen cases of nephritis we examined the toxicity of the urine by Bouchard's method, making the injection, however, not into the auricular vein of the rabbit, but into the superficial jugular. The toxicity was found to be diminished in nine cases, increased in five.

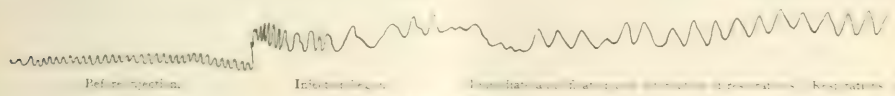
There is no necessary relation between the toxicity of the urine and the toxic condition of the organism from which the urine is derived. "The unity of toxicity or *urotoxie* [I again quote from Bouchard] is the quantity of toxicity (toxic substance) necessary to kill a kilogram of a living organism."

The urotoxic coefficient is the quantity of *urotoxie* which a kilogram of human tissue can produce in twenty-four hours. Thus: "A healthy man of 60 kgm. excretes in twenty-four hours 1,200 c.c. of urine. If 50 c.c. of this urine kill 1,000 gm. or 1 kgm. of animal tissue, 1,200 c.c., or the whole amount, will kill 24 kgm. Thus: 60 kgm. of human tissue produce and eliminate in twenty-four hours enough toxic material to kill 24 kgm. of animal. Therefore 1 kgm. of the human tissue produces $\frac{1}{60}$ of this, or ($\frac{24}{60}$) 0.4 kgm. of animal, or 400 gm. The average coefficient deduced from observation of a sufficient number of healthy individuals is 0.464; or, in other words, 1 kgm. of healthy human tissue should in twenty-four hours produce enough toxic substance to kill 464 gm. of living matter, as contained in the organism of the rabbit."[2]

The toxicity of the organism can be estimated from that of the urine only if the kidneys are in a condition normally to perform their work of elimination. Hence, under circumstances which imply that the usual amount of toxin is being elaborated in the organism, diminution in the urinary toxicity, like marked diminution in the amount of urea, itself suffices to suggest inadequacy in the secreting mechanism of the renal glands.

This inference is confirmed by the diminished toxicity of the urine in so large a number of albuminuria cases. Of healthy urine, between 30 and 60 c.c. per kilogram of rabbit's weight is required to kill the animal, the average being 45 c.c. The following cases show the diminished toxicity of albuminous urines:

CASE I.—Woman, with chronic parenchymatous nephritis; albumin, one-fifth the volume of urine in the test tube. Amount of day urine, 585 c.c. The urine was allowed to run into the superficial jugular vein of a rabbit, from a burette, at the rate of 10 c.c. per minute. The rabbit weighed 2,450 gm., and succumbed when 205 c.c. had been introduced. Thus 83.67 c.c. would have been required to poison 1,000 gm. The urinary toxicity was represented by the figure 83.67, one-seventh quantity of day urine. As the weight of the patient was not known, nor the amount of urine for the entire twenty-four hours, the urotoxic coefficient could not in this case be determined. The following tracing shows the amplification and slowing of the respiration which immediately followed the injection. The respiratory movements were collected by means of a Marey drum attached to the thorax and communicating in the usual way with a second drum, lever, and revolving cylinder. Myosis began after the injection of 10 c.c. Exophthalmos began after 115 c.c. There was no convulsion until that which immediately preceded death. This confirms the statement of Bouchard that the day urine contains narcotic substances, but not those which tend to produce convulsions.



Case I.

CASE II.—Slight trace of albumin. Urea, 23.56 gm. Urine scanty and dark, 760 c.c. A rabbit weighing 1,000 gm. was killed with 93 c.c. of urine. The patient weighed 70 kgm., and the calculated urotoxic coefficient was 0.116.

In this case there were very few symptoms of renal disease and the amount of urea was fairly adequate, but the low toxicity of even scanty and concentrated urine, and the very low urotoxic coefficient, indicated more renal inadequacy than would have been otherwise suspected. The patient's mother had died of Bright's disease a few months previous to the observation.

CASE III.—Parenchymatous nephritis. Much albumin in urine. Night urine, 475 c.c. The toxicity was represented by 88 c.c. per 1,000 gm. of rabbit. The injection was followed by a series of convulsions, the first beginning when 25 c.c. had been injected; the seventh after 164 c.c. had been injected (the rabbit weighing 1,860 gm.), and followed by death. Myosis began with 30 c.c., and the pupil was contracted to a pin point at 142 c.c.

The case illustrated the specially convulsive properties of night urine.

CASE IV.—Man, weighing 75 kgm. The urine was only slightly albuminous, but contained granular casts. The toxicity of the mixed urine was just below the normal minimum, but the urotoxic coefficient was decidedly diminished, 0.301.

[1] Leçons sur les Auto-Intoxications, p. 27, Paris, 1887.

[2] Loc. cit., p. 38.

Bouchard says that the toxicity of the mixed urines may easily appear too low, because the opposing toxic principles of the day and night urines may partly neutralize each other. The precaution of separating the two was unfortunately not observed in this case.

CASE V.—Advanced case of chronic interstitial nephritis. Patient much emaciated. Weight, about 110 lbs., or 55 kgm. Trace of albumin in day urine; amount, 960 c.c.; specific gravity, 1.005; urea, 2.88 gm. In night urine, urea, 5.965 gm.; quantity, 1,193 gm. Total quantity, 2,153 c.c. Total quantity of urea, 8.845 gm. With day urine, 221 c.c. were required to poison 1,000 gm. of rabbit, and there was only one slight convulsion, the animal dying with arrest of respiration without tetanus. With the night urine the toxicity was 174, and there were several convulsions. The urotoxic coefficent, calculated on the average toxicity of the total urine, was 0.208. The toxicity of either day or night urine was less than that of pure water, of which 90 c.c. per kilogram of animal is fatal. The toxicity of the day urine was less than that of the night, a circumstance which Teissier calls "a paradoxal character," and to which he attaches considerable importance. He had observed it in five out of twenty cases.[1]

CASE VI.—Examinations of the urine of this patient were made on several occasions and under interesting circumstances. Previous to the fall of 1893, the patient had been in apparently good health, but had had several pregnancies, which terminated either prematurely after a prolonged discharge of watery fluid from the uterus, or in the birth of a child which lived only a few hours. In the fall of 1893 the patient began to suffer from headaches and from indefinable malaise. There was at the time no albuminuria, but two or three hyaline casts in a minute urinary sediment were obtained by the centrifuge. Under a milk diet the headaches disappeared and the patient felt perfectly well. The urine was tested for toxicity as follows: The patient then being on an exclusively milk diet, with the addition of lithia water, the total amount of urine was 1,440 c.c.; the amount of urea, 34.56 gm., as calculated from the nitrogen. The morning urine was used for the injection, and the toxicity per kilogram of rabbit was 104.34.

On November 8th, after the patient had been for a week on an ordinary mixed diet including meat, the amount of urine was 810 c.c.; of urea, 17.82 gm., almost exactly half the amount excreted on milk diet. The urine submitted to the centrifuge contained three hyaline and one epithelial casts, but no albumin. Its specific gravity was 1.020. The morning urine (390 c.c. in quantity) was again used for the injection, and showed a toxicity of 97.7.

On November 15th, after a second week of mixed diet, the amount of urine was 795 c.c.; of urea, 19.875 gm. The specific gravity of the day urine was 1.025; of the night urine, 1.026, with an abundant deposit of urates. The toxicity of the day urine was 38.13, a figure within the normal range. The patient was feeling bad.

January 24, 1895, about twenty-seven months later, the patient was two weeks pregnant, and the urine was examined again. The amount was 1,283 c.c.; specific gravity, 1.011. No albumin or casts. The amount of nitrogen was 0.024 mgm. to 1 c.c., which, if attributed entirely to urea, would imply 30.792 gm. But when leucomains had first been precipitated by phospho-tungstic acid, the nitrogen estimated in the filtrate, and the urea again calculated, the amount was only 13.471 gm. The toxicity of the urine was 73 per 1,000.

The urotoxic coefficient was 0.230 (normal, 0.464). If the amount of urine required to kill 1,000 gm. of rabbit tissue be compared in these four cases with the amount of urine eliminated in twenty-four hours, further significance may be attached to the figures; thus:

October, 1893, milk diet: Amount of urine, 1,440 c.c.; toxicity per 1,000, 104.34. Proportion to amount, 1 to 13.

November 8, 1893, meat diet: Amount of urine, 810 c.c.; toxicity per 1,000, 97.7. Proportion to amount, 1 to 8.35.

November 15, 1893, mixed diet: Amount of urine, 795 c.c.; toxicity per 1,000, 39.13. Proportion to amount, 1 to 20.

January, 1895, mixed diet, pregnancy of two weeks: Amount of urine, 1,283 c.c.; toxicity per 1,000, 73. Proportion to amount, 1 to 17.57.

In other words, the poisonous dose of the urine was one-eighth, one-thirteenth, one-seventeenth, or one-twentieth of the whole amount. The poisonous qualities of the urine were evidently inversely proportional to these figures, the urine being most highly toxic when only one-twentieth of its total quantity was required to kill the kilogram of rabbit tissue, and least toxic when one-eighth of its amount was required.

The two observations were made at only a week's interval. But on November 8th the patient, although eating meat, was still under the influence of the milk diet, which had only just been interrupted and which had suited her. On the meat or mixed diet the quantity of urine had greatly diminished, and this seems to have been the reason why the toxicity of the urine, though abnormally low, was expressed by so high a proportion of the total amount. But the elimination of toxins was evidently inadequate, and at the end of the second week the patient was beginning to feel very badly. At this time, however, the toxicity of the urine had risen to normal. But apparently this was due to the large quantity of toxins accumulating in the organism under the meat diet, and not to any increase in the adequacy of the eliminative processes, so that there was reason to believe that more poison was formed in the body than, with diminished quantity of urine, was carried out of it. The patient was feeling very badly, and was relieved only upon return to the milk diet and by the attendant diuresis.

It was the diminished toxicity of urine in this case which first suggested the diagnosis of an interstitial nephritis. The diagnosis was remarkably confirmed by the subsequent evolution of the case, thus:

May, 1895, œdema of feet; attack of angina pectoris. Later, attacks of dizziness and numbness of tongue. Pregnancy continues.

September, 1895, uræmic attack indicated by thick speech, giddiness, temporary right hemiparesis; face puffy; albuminuria.

October, 1895, face puffy, albuminuria increased, granular and epithelial casts in urine, marked systolic murmur over tricuspid valve, dulness of right ventricle encroaches on sternum.

On October 6th confined of a very small child, which was completely cyanosed and breathed six hours. The placenta was markedly atrophied.

After delivery the patient suffered for a while from œdema of the lower extremities; then this disappeared, as also the albuminuria. The patient considered herself well, and again became pregnant. This time the pregnancy ran its course without uræmic accidents. At six months the urine contained no albumin, but granular and epithelial casts. At seven months an abundant albuminuria supervened and some œdema of the feet. However, the pregnancy continued to term, and this time a healthy child was born, which, five months after birth, still survives. Two weeks after confinement, however, the mother had a severe attack of double phlebitis, then an attack of pyelitis, during which the urine became almost solid with pus. After

[1] Comptes Rendus Acad. des Sciences, 1888, 7, 107, p. 172.

four months' severe illness she finally recovered, but with persistent albuminuria.

In other cases of undoubted nephritis the toxicity of the urine was diminished on one occasion and increased on another.

Case VII.—March 28th, night urine, 830 c.c., very albuminous; 6.225 gm. urea (as per nitrogen). Toxicity, 63.91. Day urine of same date, 415 c.c. Total, 1,245 c.c. Much albumin. Urea, 17.0525. Toxicity, 68. But on March 27th the toxicity of the day urine had been 11.32—an enormous increase. The patient had been taking no medicines.

Case VIII.—Nephritis of seven years' standing; neuroretinitis; abundant albuminuria; granular casts. March 8th, amount of urine, 2,500 c.c.; toxicity, 135 to 1,000—a marked decrease as thus estimated, but less marked in proportion to the large quantity of urine secreted. The proportion for poisoning to the whole amount is 1 to 18.

On March 6th the conditions were apparently the same—the amount of urine, 2,500 c.c.; of urea, 25 gm.; the specific gravity, 1.010; the toxicity was 16 c.c. per 1,000 gm. of rabbit. Convulsive twitchings began when only 16 c.c. of urine had been injected, and at 30 c.c. a violent convulsion occurred, which proved fatal in twenty seconds. The rabbit weighed 2,250 gm.; $\frac{1}{156}$ part of the total amount of urine secreted by the patient in twenty-four hours was sufficient to poison 1 kgm. of animal tissue.

Fig. 2 (Case X.).

In the next three cases either the toxicity or the urotoxic coefficient of the urine, instead of being diminished, was increased.

Case IX.—Chronic diffuse nephritis. The amount of day urine was 450 c.c., albuminous, with a specific gravity of 1.015. The urea was not diminished, *i.e.*, if all the nitrogen expressed urea, the quantity per cubic centimetre, being 0.027, would correspond to 12.15 gm. in the day urine alone. But of this urine 14.4 c.c. sufficed to poison a kilogram of rabbit. It is probable that this high toxicity was due to the diminution in quantity of the urine and consequent concentration of its toxic qualities.

Case X.—Chronic parenchymatous nephritis in a patient weighing 82.5 kgm., and taking 0.004 of bichloride of mercury three times a day. The total amount of urine excreted was 2,040 c.c.; of urea, 26.52 gm. When only 5 c.c. of urine had been injected into the jugular vein of a large rabbit, convulsions ensued—that is to say, after an exceptionally small quantity. The pupil dilated before contracting; myosis set in only after the injection of 66 c.c. Fifty-two cubic centimetres of urine per kilogram sufficed to kill the rabbit, which is an amount within the normal limits, and would seem to imply that the minute quantity of corrosive sublimate ingested had had no toxic influence. But the urotoxic coefficient was slightly increased, being 0.475 instead of 0.464 (see cut).

Case XI.—Nephritis, two months' standing. Urine, 2,600 gm. Specific gravity, 1.007. Albumin, casts; nitrogen, 0.005; urea, 13 gm. The rabbit's respiration was markedly slowed almost immediately after the injection, but the pupil did not contract at all. The urinary toxicity was represented by 50.98 c.c. per kilogram, which in itself would be normal. But comparison with the total amount of urine and the body weight of the patient yielded a urotoxic coefficient of 0.722, showing an enormous increase in the amount of toxic material elaborated by this patient's organism and eliminated in consequence of the polyuria. This fact is especially interesting in view of the small excretion of nitrogen and urea. The toxicity of the urine and its urea bore no proportion to each other, and the moderate percentage of toxic material in the urine was overcompensated by the excessive amount of urine.[1]

It seems probable that the deficiency of urea was due to an extensive destruction of the renal epithelium, and that effete matter which failed to be eliminated as urea accumulated in the organism in more toxic forms. This accumulation may be considered as the probable cause of the diuresis, since a parenchymatous nephritis of two months' duration is not likely to be associated with such local rise of arterial tension in the kidney as occurs in chronic interstitial nephritis on account of the destruction of many Malpighian bodies.

The conditions were in instructive contrast with those of the chronic interstitial nephritis of Case V. Here the prolonged disease had so depressed nutritive metabolisms that little toxic material was elaborated in the organism; the urine was scarcely more toxic than water, and the urotoxic coefficient was half the normal.

In Case X. the destruction of the eliminating apparatus had been effected with relative rapidity while nutritive metabolisms were active, and toxic material abundantly accumulated in the organism.

Case XII.—Chronic pyelitis of the right kidney of many years' standing, habitually attended with few subjective symptoms, though the urine was loaded with pus. Total amount, 760 c.c. Toxicity, 82.60 c.c.—thus decidedly diminished. The pus was filtered off before the rabbit injection was made. The urotoxic coefficient was 0.105, thus markedly diminished. In this experiment the respiration of the rabbit became accelerated, instead of slackened as usual. There was no convulsion until 57 c.c. had been injected, and no myosis till just before death.

Eight days later, immediately after the patient had suffered a severe attack of renal colic, and when she was on a milk diet and taking lithiated hydrangea, the urine was examined again. An abundance of pus was found in the urine; total amount of urine, 1,315 c.c.; toxicity, 100.4 per 1,000 gm. of rabbit; urotoxic coefficient, 0.148. Thus this, as well as the toxicity, was markedly diminished. The toxicity of the urine was almost the same as that of Case V. with incipient nephritis, in which the patient was also on milk diet, and passed in consequence a large amount of urine (1,440 c.c.).

[1] Seventy-eight c.c. of urine killed a rabbit weighing 1,530 grams. Thus: 1,530 : 78 :: 1,000 : x = 50.92, the amount of urine required to kill 1,000 grams. 2,600 c.c., passed in twenty-four hours, would kill as many kilograms of rabbit as 50.92 could be contained in 2,600 = 51, or 51,000 grams. As this amount was elaborated by a man weighing 66 kilograms, 1 kilogram of his body would kill $\frac{51000}{66}$ = 0.772 kilogram, the urotoxic coefficient.

It is noticeable that although the percentage of toxicity was lower in the second than in the first experiment with the same patient, the urotoxic coefficient was higher. Toxic elimination was actually increased, but the increased diuresis reduced the percentage of urinary toxicity.

A milk diet, by cutting off the important source of urinary toxins contained in meat, is expected to diminish the toxicity of the urine, not only relatively but absolutely. But if the urotoxic coefficient be higher, we must infer either that on the milk diet nutritive metabolisms had been increased and a greater quantity of toxins elaborated in the organism, which compensated for the privation of meat toxins; or that elimination had been increased, the tissues more thoroughly washed out, the result being expressed in the larger quantity of urine secreted.

This patient, in the intervals of acute exacerbations of her chronic pyelitis, considered herself quite well. The first of the above observations was made five days after a severe attack of acute renal colic; the second, three days later and at the beginning of an illness prolonged several weeks, and attended with such tumefaction in the region of the affected kidney as indicated a perinephritis. The diminished toxin elimination coincided with a period of acute renal inadequacy grafted on the chronic disease which lay outside the secreting apparatus. No opportunity was afforded to examine the urine at a time when the patient was free from subjective symptoms. Three years from date, and after a prolonged residence in Bermuda, she claims to be in good health, though the pyuria persists as before.

Case XIII.—Symptoms indefinite. Square-topped sphygmographic trace of lithæmia, with a maximum developed under pressure of 9 oz. Urine (lithia medication), 1,170 c.c. Total urea, 14 gm. No albumin; some broken granular casts; large renal cells; many leucocytes. Specific gravity, 1.015. Urinary toxicity, 64.51, or just below Bouchard's minimum. The patient returned to Texas, and the evolution of her case is not known.

The following cases did not present symptoms of renal disease, but more or less pronounced indications of lithæmia:

Case XIV.—Woman, sixty years old, living on milk and grape diet. Pupil of injected rabbit dilated markedly before myosis set in. Urine fatal at 145 c.c. per kilogram; urotoxic coefficient, 0.231—about half the normal. This may be attributed to the diet, upon which the patient was thriving. A diagnosis of myocarditis had been made three months previously.

Case XV.—Had suffered from muscæ volitantes; otherwise robust. Urine albuminous; urea, 21.90 gm., but urinary toxicity, 84. Myosis was not induced in rabbit till 68 c.c. had been injected.

Case XVI.—Hysteria and lithæmia, frequent headaches. Urine scanty, but not at all high colored; amount only 550 c.c. Nitrogen, 0.009 per cubic centimetre. Urea, 4.95. The urinary toxicity was 62, only slightly diminished—diminution not in any way proportionate to the diminution in the amount of urea. This fact, taken together with the symptoms of auto-intoxication frequently presented by the patient, implies that the same perversion of metabolism (perhaps especially in the liver) which lessened the formation of urea had increased the formation of other toxic excretory material.

The urine of one diabetic patient was examined with peculiar results:

Case XVII.—The woman was enormously stout, weighing 200 lbs. The glycosuria was moderate, had lasted only a short time. The patient suffered from loss of strength and constant thirst, but no bulimia. The amount of urine passed was 2,880 c.c., with 37.44 gm. of urea. Into the jugular vein of a rabbit weighing 1,320 gm. was injected 185 c.c. of urine without causing immediate death; the urinary toxicity being thus less than 140 c.c. per kilogram of animal. Moderate convulsions occurred at the beginning of the injection, but none after 19 c.c., and no myosis occurred till 150 c.c. had been injected. But when the injection was interrupted, signs of pulmonary congestion had appeared, and the animal was found dead the next day. The lungs were intensely congested.

As there was no renal disease, the defect in the urinary toxicity must be attributed to defective elaboration in the normal toxins of the organism, or at least to a defect in their elaboration into such forms as would seek elimination by the kidneys. The normal convulsibility of the urine may have been neutralized by an unusual proportion of narcotic toxins, which did not tend to kill the animal directly, but indirectly through pulmonary congestion.

Case XVIII.—The urine was examined in one case of epilepsy, thirty-six days after one attack and twenty-four days before another. The patient was taking bromide of lithium and chiefly milk diet, and the amount of urine was 1,331 c.c. The injection caused only slight convulsions in the rabbit, but very abundant diuresis. The toxicity of the urine was expressed by 120 c.c. per kilogram—half the normal minimum. The urotoxic coefficient was 0.170. No opportunity was afforded to examine the urine just before or after an attack.

Féré,[1] examining a series of epileptic patients, found that the urine just before the paroxysm gave an excessive urotoxic coefficient in seven out of eight cases. However, in five out of the eight cases the urotoxic coefficient remained excessive also after the paroxysm.[2] In these cases the paroxysms were so frequently repeated that there was no reason to suppose an intermittent accumulation of toxins in the organism as a cause of the attack—rather a condition of chronic hypertoxicity, possibly due to intestinal fermentations, not relieved by the convulsive attacks or coincident with them, but persisting as the attacks recurred.

Deny and Chauppe found, in ten out of thirteen epileptic patients, a moderate diminution of urinary toxicity, represented by 60, 80, 90 c.c. required as fatal doses. But the amount of urine was so much increased, that the urotoxic coefficient did not greatly differ from normal. In another patient, who passed only 750 c.c. of urine, this proved fatal at a dose of 20 c.c. per 1,000 kgm. of rabbit.[3]

Voisin examined the urine of epileptic patients subject to attacks in series. He found that the urine was hypotoxic before and during the series, but that the toxicity rose and exceeded the normal if the series had really terminated, but failed to do so if further attacks were destined to occur. The examination of the urine by this method, therefore, offered important data for the prognosis. When the epileptic patients had become demented, the urine was constantly hypotoxic.

Chambulent[4] showed that the serum of the blood became more and the urine less toxic during a series of epileptic attacks.[5] "When albuminuria coexists," observes Voisin, "the elimination of toxins is slackened, and their accumulation may become as dangerous as in acute infectious diseases. The *état de mal* is established, and the temperature rises."

Lanoine compares epileptic crises to the crisis which marks the decline of an infectious disease.[6] "Auto-

[1] Comptes Rendus Soc. Biol., 1890.

[3] *Ibid.*, November 30, 1889.
[4] *Ibid.*, February, 1892.
[5] In 1897 Herter showed the same thing in regard to attacks of puerperal eclampsia. (Trans. N. Y. Acad. Medicine, 1897.)
[6] Gaz. des Hop., 1889.

intoxication is the principal element of the paroxysmal attack, but the auto-intoxication is favored by the condition of the nervous system, which is defective through heredity or acquired deterioration."[1]

A few experiments were made with the urine of women immediately after their confinement, on the supposition that the processes of tissue involution would throw a large amount of detritus into the circulation, whose ultimate products would be eliminated with the urine and thus increase its toxicity. The few experiments made, however, showed that this condition of hypertoxicity was insufficient to counteract the effect of the low diet of the puerperal *régime;* or else that such elimination did not become active before the sixth day. For convenience these facts are thrown together in the following table:

Name.	Day after Confinement.	Urinary Toxicity per Kilogram.	Urotoxic Coefficient
Case I.....	First	100 c.c.	0.037
	Fourth.	160 c.c.	
Case II.....	Third.	92	0.179
Case III.....	Fifth.	96.5	0.238
Case IV. Albumin; casts; urea, 7.29; milk diet.	Second.	86.16	No uræmic symptoms.
	Sixth.	29	
	Seventeenth.	34.01	
Case V. ...	Third.	81	

In the fourth case the rise of toxicity on the sixth day to a little above the normal minimum was all the more noteworthy because the urine was albuminous, a condition habitually associated with hypotoxicity; and because, on account of the albuminuria, the patient had not been restored to the usual mixed diet, but was living exclusively on milk diet.

In three women observed just before confinement, the urine was hypotoxic. Of these the first, the albuminuria patient of the preceding table, was on a milk diet; the others were on ordinary mixed diet.

Case I....	Two days before confinement.	Urinary toxicity, 94 per kilogram.	Two days after, toxicity, 86.16.
Case II....	Three days before confinement.	68	Three days after, toxicity, 92.
Case III....	Fifteen days before confinement.	97.7	

The injection of the last patient's urine into the jugular vein of a female rabbit caused the latter to abort of three young animals nearly at term, of whom two were alive and lived for fifteen hours. Only 30 c.c. of urine had been injected when the abortion occurred.

Abortion is not a necessary consequence of the injection of such a small amount of urine, for after the death of a rabbit killed with a much larger amount five fœtuses have been found in the uterus of the mother. It would seem, therefore, that the abortion in the above case was due to the specific action on the uterine spinal-cord centres of a toxin contained in the urine, and not, as might plausibly be supposed, to a simple mechanical disturbance of the circulation.

The diminished toxicity of the urine during pregnancy, as noted in the above cases, corresponds with the results of Chambulent's observations. In a series of six cases of pregnancy near term, this experimenter found the urotoxic coefficient to range from 0.22 to 0.35—an average of 0.25 (normal, 0.464). To whatever this diminished urinary toxicity be due, we may, from the nine cases (three of them ours, six of them Chambulent's), infer that it is the normal condition, and a deviation from it to imply something abnormal, hence possible danger.

In two other cases of women observed just before confinement, the urinary toxicity was not diminished, but remained within the limits normal to the non-pregnant state. This fact was all the more significant, because at a previous confinement one of these women had suffered from convulsions, and during this pregnancy had a slight albuminuria.

Case I.....	Daily expecting confinement.	Urinary toxicity, 56 per 1,000.	Amount of urine, 1,040 c.c.
Case II. Had convulsions at previous confinement; at present has albuminuria.	Daily expecting confinement.	29	576 c.c.

A larger number of observations on puerperal urine is a great desideratum, in order to ascertain whether at this time and for any reason the usual law is reversed, so that while the diminution of toxicity is an alarming circumstance in nephritis, it should be the normal condition at the close of pregnancy. May it imply that general tissue metabolisms are slackened in intensity during the concentration of nutritive energy upon the spinal centres about to enter upon the tremendous effort of parturition? If defective elimination were the cause, puerperal accidents due to an accumulation of toxins in the body might be expected to occur far more frequently than they do. Therefore it would seem more probable that at this time a smaller amount of toxic substance is elaborated, thus lessening the strain to which the organism is to be exposed during the accumulation of detritus after the confinement. At this time the urinary toxicity should normally be expected to rise. We have had as yet no opportunity to examine the urine earlier in pregnancy.

Our observations in cases of renal diseases tend entirely to confirm the dicta of Teissier: "The toxicity of the urine offers signs of the greatest importance for the prognosis of albuminuria. The toxicity varies inversely with the aggravation or amelioration of the disease. The urinary toxicity may vary from day to day. A large amount of albumin in the urine is important only if the renal elimination be incomplete. A urine containing only a small quantity of albumin may nevertheless indicate very serious disease if the renal elimination be insufficient; thus in interstitial nephritis, where Professor Bouchard has shown that the toxicity of the urine is always diminished. In some cases the urotoxic coefficient falls to 0.193, 0.146, 0.123 [see our Cases II., IV., V., VI.]. Albuminuria in kidney disease becomes a symptom of second rank."

Teissier cites two cases where in apparently grave disease, he gave a favorable prognosis based on the normal or even excessive toxicity of the urine, and in both cases the prognosis was justified by the result. The first was an albuminuria with colloid casts in the urine, but with a urotoxic coefficient of 0.490 (normal, 0.464). It was subsequently discovered that the albuminuria was due to a renal calculus.

In the second case there were a rheumatic nephritis and a *bruit de galop* at the heart, with frequent syncope. But the toxic coefficient of the urine was 0.664, indicating that the kidneys were doing their full duty; and the patient recovered so completely as to be accepted in the army.

In the case of pyelitis (Case XII.) the low urinary toxicity and urotoxic coefficient seemed to indicate an extension of disease from the pelvis to the parenchyma of the kidney. Yet it is possible that the renal inadequacy was functional and independent of any serious anatomical lesion, for not only did the patient

[1] Voisin, l. c. Herter's experiments in auto-intoxication in epilepsy were centred on the estimate of ptomains in the urine, as shown by its content in ethereal sulphates. N. Y. Medical Journal, 1889.

entirely recover, remaining in fair (subjective) good health three years later, but she had recovered from similar attacks at least half a dozen times in the course of eight or ten years, no symptom remaining between the attacks but the pyuria. Of the two experiments made in this case, the first preceded, the second followed a severe attack of renal colic. On the first occasion the patient was taking an ordinary mixed diet; on the second, was living exclusively on healthy persons, noticed that an exclusively milk diet, to the amount of three or four litres a day, markedly increased the toxicity of the urine; and observes that "the primary cause of urinary toxicity must be sought in the phenomena of intimate molecular nutrition"—thus not, as Bouchard would have it, primarily in the diet or in absorption from the intestine.

In Case V. diminution in the urinary toxicity was the first positive indication of renal disease, which

No.	Nature of Case.	Amount and Character of Urine.	Weight of Rabbit.	Amount of Urine Injected.	Amount in c.c. per 1,000 gms. of Rabbit.	Weight of Patient.	Urotoxic Coefficient.	Remarks.

Idem; 2 days earlier.	Nephritis 7 years; neuroretinitis; milk diet; strophanthus.	Amount = 2,500 c.c.; much albumin; granular casts.	1,800 "	30 c.c.	16⅔ c.c.	.....	....	Could discover no reason for this enormous exaggeration of toxicity, especially as the amount of urine was the same, and the medicine unchanged.
9	Chronic diffuse nephritis.	Day urine = 450 c.c.; albuminous; specific gravity, 1.015; urea = 12.15.	1,180 "	17 c.c.	14 c.c.			
10	Chronic parenchymatous nephritis; 0.004 bichloride mercury ter in die.	2,040 c.c.; urea = 26.52 gm.	2,090 "	110 c.c.	52 c.c.	82.5 kgm.	0.475	Convulsions began after only 5 c.c had been injected.
11	Nephritis 2 months' duration.	2,600 gm.; specific gravity, 1.007; albuminous casts; urea = 13 gms.	1,530 "	78 c.c.	50.98 c.c.	66 "	0.772	No myosis.
12	Chronic pyelitis of right kidney.	760 c.c. loaded with pus; filtrate from this used for injection; urea = 7.98 gm. (filtrate from leucomains).	1,150 "	95 c.c.	82.60 c.c.	88 "	0.105	Respiration accelerated instead of slowed.
Idem 8 days later.	Immediately after severe renal colic; milk diet and lithiated hydrangea.	1,315 c.c.; filtrate used; urea as estimated in supernatant fluid after precipitating leucomains = 32.50 gm.	1,742 "	175 c.c.	100.4 c.c.	88 "	0.148	

milk, and taking, in addition, lithiated hydrangea. Under these circumstances the quantity of urine was considerably increased, and the urinary toxicity considerably diminished—from 95 (already abnormally low) to 175. Nevertheless, the urotoxic coefficient rose from 0.105 to 0.148, and the proportion of urine required for a fatal dose, which was as much as one-eighth before the acute attack, fell after the attack to one-thirteenth of the whole amount passed in twenty-four hours. The concentrated urine before the attack was thus really less toxic than the dilute urine which followed; and although meat is held by Bouchard to constitute a principal source of urinary toxins, yet in this patient the urine from the meat diet was proportionately less toxic than that from the diet of milk. Lapicque, experimenting on two

became fully developed later. Discovery of this latent disease was all the more important, because it seemed to help to explain the accidents of five successive pregnancies, which were either terminated prematurely or resulted in the birth of non-viable children. There remained a mystery, however, for in the sixth pregnancy granular casts were present in the urine, and abundant albuminuria developed during the last six weeks; yet a healthy child was born at term, and five months later was still living and thriving. The acute pyelitis which developed a month after delivery suggested the possibility that the albuminuria which had previously existed, but only at long intervals and in the last month or two of successive pregnancies, had really been due to a catarrhal pyelitis, and not to parenchymatous disease; while the

other symptoms—diminished urinary toxicity, secondary[1] indigestion, transient uræmic aphasia and paralysis, chorion dropsy, and atrophy of the placenta—would be attributable to a more insidious interstitial lesion, which for a long time spared the secreting epithelium and the Malpighian tufts, and caused no albuminuria.

Sufficient comment has already been made upon the single case of epilepsy submitted to experiment.

The single experiment in diabetes gave remarkable results, and such as I have not seen elsewhere recorded.

UNEXPECTED FORMS OF DEATH AMONG THE INSANE.

By E. M. SOMERS, M.D.,

ASSISTANT PHYSICIAN, ST. LAWRENCE STATE HOSPITAL, OGDENSBURG, N. Y.

In every hospital for the insane a certain percentage of deaths will occur without any warning, save those symptoms which are intimately associated with the moribund state; and such occurrences set one to thinking whether some signs or symptoms ought not to have been observed during the usual condition of the patient to put the physician on his guard, although knowing that no essential treatment would have more than modified or delayed the occurrence. Again, one congratulates himself that such deaths did not happen while the patients were under some vigorous treatment, medical or surgical, or during the course of forced feeding or surgical restraint.

Of the many causes of sudden deaths among the insane, cerebral apoplexy and embolism are not uncommon, and these seldom present symptoms or lesions so remarkable as to need reporting. Ruptures of the heart, larger arteries, and liver are much less often found, and therefore make more striking impressions. Still, there are now and then cases showing but a scanty array of symptoms. The patients suddenly sink to the floor, with face intensely congested, and very rapidly pass into a fatal coma; or, partially arousing, become restless for a time, and expire in a few hours. During life such cases, which are essentially senile, show mentally the ordinary symptoms of dementia, and physically increasing feebleness of health. The heart action is generally feeble, the arteries are much sclerosed, the urine always contains albumin, and mild uræmic attacks are common. At the necropsy we find the ordinary signs of arterio-sclerosis and cirrhotic kidneys. The heart is possibly soft and its muscular fibres are flabby and easily lacerated; or, conversely, the muscle may be quite firm, and upon close inspection we may be able to observe the striations cloudy and indistinct, the aortic intima containing atheromatous and calcareous patches, most plentiful about the coronary ring, while the brain seems macroscopically unchanged save for some general softening.

A case in detail may illustrate the above description.

Case I.—Male, aged forty-four years, German, farmer; alleged habits temperate; duration of attack previous to admission, four years; diagnosis, terminal dementia. His history is that of an ordinary case of maniacal excitement before admission, followed by dulness and confusion, neglect of person, etc. During the patient's life in the institution (nearly five years) he showed very early the evidences and facies of a dement, occasionally having outbreaks of loud talking with motor restlessness, and seldom making assaults. Soon his physical state showed beginning enfeeblement as evinced by poor nutrition, increasingly feeble gait, and dyspnœa upon exertion; the urine from time to time showed albumin and casts. It might be well to state that the physical examination upon admission showed no organic changes. During the last month of the patient's life all the symptoms of enfeeblement, both of mind and body, were intensified. His periods of usual disturbance would tire him very noticeably, and he would perspire profusely even when not especially exercising. On April 15, 1897, he showed no unusual symptoms other than those above described, except a tendency to restlessness. While walking along the floor he suddenly sank with face intensely congested, remained in this comatose condition only a few minutes, and expired. The necropsy showed the brain substance to be slightly softened, nothing further. The cerebral arteries were sclerosed, the cerebro-spinal canal and ventricles were filled with clear fluid. The heart was contracted, the left ventricle hypertrophied, the muscular tissue pale and showing fine granular striæ throughout its stroma, but its substance was of fairly good consistence. The aortic intima and valves were crusted with patches of atheroma and lime. Liver nutmeg; kidneys large and tough; capsules non-adherent; surface of kidneys nodular; cortex atrophied; markings indistinct.

Case II.—Female, aged sixty-three years, Irish; habits said to be good; by occupation a domestic. She presented essentially the same mental symptoms as the patient in Case I. On admission she was in poorer physical health, however, and gradually became more and more enfeebled. Occasionally the patient would remain in bed for a few days. Frequent examination of the urine always revealed casts and albumin, and during her latter days œdema of the feet and muscular weakness were noted. January 13, 1897, the patient was observed to have slight spasms of the right arm and leg with dilatation of the right pupil. The attending physician was called and found the arm in marked spasmodic movements, though of a feeble character. The right pupil was widely dilated, the left apparently normal; the jaw was dropped and the tongue apparently paralyzed. From the above condition she passed into one of stupor with right hemiplegia, and a few hours later expired; but for a short time previous to death she was feebly restless. The autopsy showed the following important conditions: calvaria thin, porous, and difficult to remove, due to quite firm adhesion of the dura, especially along the posterior convexity. The sinuses were engorged, the pia was much injected, and a large quantity of cerebro-spinal fluid was collected; the brain substance was of good consistency. The cerebral arteries, especially at the base, were very much degenerated, containing calcareous plates and surrounded by yellowish patches. The ventricles were distended with fluid. Careful sections of the entire brain substance showed to the eye no sites of hemorrhage or of softening. Heart in diastole; considerable deposits of fat about the base of the ventricles; myocardium soft, easily macerated, and of cloudy appearance; valves thickened, indurated, and contracted. Liver small, dark-colored, nodular, and its substance in appearance "nutmeg." Kidneys typical of advanced interstitial nephritis.

Both of these subjects were uræmic, and the cause of death could safely be attributed to nephritis. The mode of death, however, was unusual and in an unexpected form, as neither had had coma before, or any of the severe symptoms of uræmia. Pepper[1] says: "Hemiplegia, with or without aphasia, may be the first symptom to call attention to a nephritis. . . . There is loss of motion alone, or of both motion and sensation." Case II. had hemiplegia with aphasia. Sensation in the paralyzed parts before stupor supervened was indefinite, owing to the patient's confused mental

[1] As distinguished from indigestion in the *prime* [illegible]

[1] "American Text-Book of Theory and Practice," vol. ii., p. 653.

state. Further he says: "These attacks have been ascribed to localized œdema of the brain." And: "In cases that I have seen there were no changes in the brain tissue, but the cerebral arteries were damaged by chronic endarteritis." The brain in this case was waterlogged, but no one locality seemed more especially œdematous and no hemorrhagic foci were revealed. Nevertheless, there were abundant evidences of advanced cerebral endarteritis, and the perivascular spaces were prominent throughout the entire brain substance. On the following page he says: "Persons apparently in good health are attacked without warning by convulsions, coma, delirium, or hemiplegia. . . . They may die in the first attack or live to go through subsequent ones." Case I. seemed to be of the comatose type, which rapidly became fatal. The brain was less waterlogged than in Case II., but had nearly as much arterial degeneration. The myocardium showed neither fibroid nor fatty changes to the eye, and the coronary sinuses were freely open. At no time in his history were there attacks indicating a possible angina pectoris and his last symptoms were of an apoplectiform character. Examination of the urine shortly after death showed the presence of the usual amount of albumin. Although the symptoms and evidences do not so strongly point to a fatal angina, yet the symptomatology in a dement must obviously be obscure, and in this case the cause of death be necessarily an open one.

Rupture of the heart has been the cause of death in less than two per cent. of cases at this institution. Occasionally one will read of this occurrence among the insane. Dr. Mickle, in the February number of the *Edinburgh Medical Journal* for 1884, reported three ruptured hearts. Dr. Pilgrim, in the *Journal of Insanity* for January, 1895, mentioned one similar case. Another was presented by Dr. Tompkins, in the *British Medical Journal* for May, 1885. Three out of these five ruptures were in cases diagnosed as melancholia; another was a case of senility with marked states of depression. The remaining one was terminal dementia due to chronic alcoholism. In four of these the site of rupture was in the body of the left ventricle. The fifth case, however, had the rupture in the right ventricle. Again, in three out of the series death occurred rather slowly. There are two other cases which the writer desires to add to the list:

Case I.—Female, aged eighty-one years, widowed, native born; habits good; occupation, domestic. Diagnosis, senile melancholia. Cause, epidemic influenza. Before admission she was depressed to a mild degree, neglected to care for herself, and became very hypochondriacal. During the fifteen months the patient was here she presented no interesting mental symptoms other than those commonly found in a large majority of senile melancholiacs. Her physical condition upon entry was feeble; pulse very fibrous: heart action fairly good and without murmurs. Lungs normal. Urine showed no albumin or casts. General enfeeblement kept her in bed frequently while here, but her usual condition immediately before her death seemed to be in no wise more decrepit. The circumstances pertaining to her death were simply that the night nurse found her in a condition of collapse about 4 A.M. The pulse was feeble; she breathed gaspingly, and soon life was extinct. Autopsy showed the following interesting facts: The brain was not structurally changed, though the basal arteries were markedly atheromatous. There were a number of foci of softening in the basal ganglia, some being as large as a pin's head. Lungs slightly œdematous. Liver softened and showing granulo-fatty changes. Kidneys of the moderately cirrhotic type. Heart in partial systole; myocardium firm; pericardium contained about one ounce of bloody serum. On the anterior surface of the left ventricle was noted a purplish extravasation running lengthwise of the organ for about two inches, giving to the touch a feeling of hardness surrounded by a dissolution of continuity. At the apex, involving the muscular substances of both ventricles and intermuscular septum, was an area of very friable muscular tissue mingled with clotted blood. The muscular fibres were ruptured and separated in the centre of the degenerated spot, yet the visceral pericardium was intact, so that there was no actual external communication. At one site under the injected area on the anterior surface of the left ventricle was a thick coagulum looking like muscle detritus, mingled with a thrombus, and through the centre of this mass the walls were attenuated to a layer of tough connective tissue, enclosing this purplish softened tissue, and the whole was held in place by the endopericardium. Attempts to reach the site by a probe in the coronary artery failed. The cardiac valves were thickened but apparently competent. Plaques of thickening were noted in the aortic arch. The kidneys were contracted and cystic to a mild degree.

Case II.—Female, aged seventy years, Canadian; domestic; a morphine habitué. Her tendencies before admission were suicidal, she having jumped from a second-story window. Duration of attack, several years; cause unknown. Diagnosis, dementia (senile). The accompanying history stated in substance that the patient thought the pain which had been constantly in her stomach for seventeen years was due to "a nest of cats" therein, and that she jumped from the second-story window "because the devil was in her." She was loud in her demand for arsenic, that she might quiet the pain or do away with herself. On admission the patient was emotional, agitated, and depressed, repeating constantly, "Give me arsenic." The physical condition was feeble, with indistinct heart sounds, though no murmurs could be detected. After the patient had been at the hospital a few weeks she was daily given a dose of morphine for its possible mental effect, but the rest was temporary. During her life here the patient was entirely absorbed in the one idea that animals, "cats," "little pigs," etc., were "gnawing" her stomach, and she was almost hourly pleading to be cut open so that the animals could be removed, or to be killed and freed from pain. Repeated physical examinations were made with unsatisfactory results, as she kept the muscles over the epigastrium rigid. Although her appetite was poor, she accepted a varied diet and showed no symptoms pointing to any organic changes of heart, stomach, or liver. There was a continued failure of physical strength, the last few months the patient remaining in bed much of the time. One morning while walking along the floor she suddenly fell unconscious, and quickly expired without further symptoms. The post-mortem evidences of importance were as follows: Heart relaxed; pericardium filled with about one and a half pounds of blood clot; myocardium very soft and of a cloudy appearance. At the left ventricular apex a small rent was detected in the muscle wall externally, communicating with a cavity. The muscular tissue about the rupture was blood-stained and very much softened. Nothing in other viscera was of interest beyond the evidences of common senile changes.

The two cases just detailed resemble in two points the five cases summarized: 1st, they were senile; and, 2d, mentally depressed—the sites of rupture differing, however, in that they were both apical.

Anæmic necrosis, a term used to indicate localized degenerative changes taking place in the myocardium as the frequent result of an obliterative endarteritis of the coronary branches, seems to have been well pointed out in Case I. The patch on the anterior ventricular surface, evidently of long standing, showed

its centre to be quite sclerotic. The ruptured site at the cardiac tip was an acute aneurism.

In Case II. the heart muscle in general was much more softened, and it would be difficult to attribute this apical rupture to a myomalacia cordis, at which site it is reported as most frequently occurring, in preference to the possible fact of this spot being simply the more advanced in the grand fatty decay. The more interesting feature of Case II. is the very well-defined illustration of "coanæsthetic illusions" of Regis,[1] who says: "There is a special class of illusions which cannot be properly referred to any of the special senses, and which are known by the name of internal or coanæsthetic illusions. . . . They consist in false interpretations of actual organic sensations. . . . Thus very frequently affections of the intestines, the stomach, or the uterus, induce in the patients, by the reaction they cause, ideas that they have animals in their bellies, that they have been violated, etc. . . . These internal illusions are especially frequent in the so-called sympathetic insanities." The reflex action of an organic heart disease was referred to the epigastrium (probably in the form of an intense neuralgia), and the ideas held by this patient that animals, "mice," "cats," etc., were "gnawing," were truly typical of a symptomatic or cardiac insanity.

The last case to be reported is one of a traumatic rupture of the liver. Male, Prussian, aged fifty-one years, single, baker. Habits intemperate; duration of insanity, ten or twelve years. Diagnosis, terminal dementia. His mental history is uninteresting, as it is characterized throughout by the classical symptoms of early involution. His physical state, which was fairly robust till about three years ago, gradually became more and more frail until he presented the anæmic and drawn features of one possibly suffering from chronic pulmonary tuberculosis. The man's gait, which was always feeble, was much hampered, owing to the fact that his left foot had been amputated. On March 10, 1897, while walking along with a number of other patients, he was suddenly pushed with considerable force against the wall by another patient. Shortly after he sank to the floor in a condition of collapse, and soon life was extinct. The necropsy, which was performed in the presence of the coroner, gave the following data: Calvaria unusually dense and heavy; brain well formed and presenting no gross changes. Heart relaxed; myocardium firm; valves slightly thickened. Lungs partially collapsed and anæmic. When the abdomen was opened, about four pounds of free blood was found in the peritoneal cavity, and the source of the blood was discovered to be a rent in the liver substance. The site of rupture was about the central part of the right lobe on its antero-superior surface. The tear was four inches long by two and a half inches in depth, with ragged edges, and running in an antero-posterior direction. The liver substance was in a state of marked granulo-fatty degeneration, and but little effort was necessary to tear or break down any part of the putty-like organ. The site about the rupture was not more degenerated than usual. The seventh and eighth costal cartilages were fractured opposite the liver lesion, and a moderate bloody extravasation in the cellular tissue covering these cartilages was detected. No skin evidences of injury were apparent.

The general opinion in this case seemed to be that the patient was crowded and squeezed against some firm object, so that a sufficient amount of pressure was exerted to cause a rupture of the already diseased gland.

To Prevent Nausea after Chloroform.—Pour vinegar upon the mask after the operation and let the patient inhale as he is coming to.

THE RELATION OF SEX TO MENTALITY.

By CHARLES A. WHITE, M.D.,

Much has been written, especially by German authors, concerning the relation of sex to mentality from the standpoints of psychology, criminology, and social science, but it is my purpose only to remark briefly upon that relation with reference to the sequelæ of surgical operations upon the sexual organs, especially those of ovariotomy. The literature of those sequelæ is extensive, but it is all, or nearly all, confined to the physical and pathological conditions which result more or less directly from the operation. That is, judging from the literature referred to, the possible effects of ovariotomy upon the mentality of the patient has rarely been taken into consideration by the operating surgeon. This assumed fact has lately been called to my attention in a somewhat forcible manner.

A daughter each of three friends of mine has been made the subject of ovariotomy, each by a different surgeon, neither of whom was cognizant of the other cases. One case was that of a woman, aged thirty-eight years, the mother of three children; another that of an unmarried woman, aged thirty-nine years, and the third that of a girl of eleven years. All three of the operations were successful, as such. The two women are living in good physical health and unimpaired mentality. The girl died after complete recovery from the operation, but before reaching the usual age for the establishment of the menses.

In each of these cases the father unsuccessfully solicited from the surgeon some prognosis of the probable effect of the operation upon the mentality of the patient. Being men of broad information, they fully comprehended the general character of the operation and were also well aware of the reputed psychological effect of castration upon the human subject. They therefore naturally inferred, or feared, that a similar result might follow the removal of the ovaries. The necessity for the operation seemed to be imperative, and they consented without further questioning.

After the operation in each case had been performed and recovery from its immediate effects practically assured, the father of each patient conferred with me, not professionally but as an intimate friend, upon the question they had respectively raised with the surgeons. I could not reply from any actual experience of my own in surgery, nor could I refer them to any literature bearing directly upon the question, for I had vainly sought for it in the great library of the United States Army Medical Museum. I had, however, given some attention to related subjects, and the following remarks embrace the substance of my replies to their inquiries. They are based largely upon the proposition that sex and a certain phase of mentality or of psychological manifestation are intimately correlated in their development.

While the greater part of the sum total of human mentality is developed in like manner and is of similar quality in both sexes, it is too obvious to need more than passing mention that certain prominent mental characteristics are peculiar to each. It is also just as obvious that differences of mental habit, and one might almost say of instinct, exist between the two sexes in childhood, and that those differences are strongly marked before the age of puberty. At that age the differences quickly merge into the peculiar psychological attributes of manhood and womanhood respectively. Those attributes being due to sex, it necessarily follows that if the ovaries or testes, the primary organs of sex, should not be potentially developed, or if they are removed before the full establishment of manhood or womanhood, as the case may be, the development of those psychological character-

istics which distinguish the sexes respectively will be thereby arrested. Thus, as is shown by the published records of eunuchism, if a boy be castrated in childhood, although his body and a large degree of general intellect are subsequently developed, certain features of his mentality remain deficient. That is, he is characterized throughout his whole life by an unmistakable puerility of thought, effeminacy of habit, and a lack of manly responsibility of conduct.

The absence of an actuating motive for and the difficulty of the operation of ovariotomy, as compared with that of castration, has doubtless prevented the barbarism of man from mutilating woman as he has done his fellow-man, and therefore ovariotomy in childhood is unknown except as a remedial operation. Furthermore, such diseases of the ovaries as require their removal rarely occur before the age of puberty, and consequently only a few cases of ovariotomy before that age are known to surgery. Some, however, are known, and from its analogy to castration one cannot doubt that in all such cases certain girlish or immature mental characteristics will remain throughout life. The changes which take place as a result of early castration present the strong contrast with the natural male condition which exists between virility and effeminacy, but because of the more delicate nature of woman it is not to be expected that so great a contrast will be the result of ovariotomy. Certainly no converse tendency toward mannishness is to be expected. Still, it is reasonable to expect that the psychological deficiencies produced by ovariotomy upon an immature patient may be so strongly marked as to be a source of grief and disappointment to her friends. In these cases at least it is within the province of the surgeon to inform the friends of the patient as to the mental as well as the physical condition in which she will probably be left when the wounds are healed which his knife has made.

Modern surgery has made ovariotomy, in competent hands, one of the safest of the capital operations, and recovered subjects of that operation are therefore somewhat numerous. And yet, as already mentioned, no satisfactory records of their mental sequelæ seem to have been published. This deficiency of record is doubtless due, not to remissness on the part of surgeons, but to the extreme difficulty of obtaining accurate information of this kind. The sequelæ referred to are manifested, if at all, after the case has passed out of the surgeon's hands and, for obvious reasons, the friends of the patient do not willingly make them public. Therefore the doctrine of probabilities must enter largely into any prognosis of such sequelæ, and it legitimately suggests the following statements, as it has some of those made in preceding paragraphs:

While it may be expected that the full establishment of the attributes of womanhood will secure the subject of ovariotomy from adverse mental effects, it is possible that if the operation be performed in the first years of her potentially fertile period there may result some degree of impairment of the sexual phase of her mentality, because it requires a few years after the appearance of the menses fully to establish the mental habit of womanhood. It is believed, however, that if such a result should occur it would be too slight to be observed by any but her most intimate friends. In all the cases here suggested it is assumed that both ovaries are removed, for the removal of one ovary does nor necessarily prevent subsequent fertility.

After the middle or later part of the period of potential fertility no degree of mental impairment is to be reasonably expected as a result of ovariotomy. In all such cases the surgeon's knife transfers the patient to that respected condition of non-fertility which is the natural heritage of every woman who reaches her later sexual climacteric and she is transferred to that condition only a little in advance of the time when she would naturally have entered it. That is, the mental condition is no more changed in the one case than in the other, and, save for the loss of a little diseased and therefore worthless tissue, the physical condition of the recovered patient is the same as is that of the woman who becomes infertile by the natural process.

In support of my proposition that certain childish characteristics are likely to remain with those who have been deprived of the essential element of sex in childhood, as well as with those in whom it may have never been developed, I gave the three friends referred to the following illustration drawn from my experience with mule packtrains in Western exploration. The low grade of these animals, as compared with man, does not make the illustration inapt, because it is only a small part of that great aggregate of human mentality which distinguishes man from those animals that is specially affected by sex. Therefore the contrast in this illustration is not so great as it might appear to be.

Mules are more serviceable for packing than are any other animals, but they cannot be managed alone with full success. Therefore a horse, much preferably a female, is always provided to lead them. She wears a small bell and is called the bell mare. The train marches single file, and at the first start it is the settled ambition of every mule in it to march next the bell mare. A contest takes place with much kicking and biting, the strongest or most persistent one secures the place, and the others gradually fall into line. After the first or second day out every mule knows its place in the train and keeps it without further trouble.

Upon those marches the animals subsist wholly upon the grasses which grow along the route. When they are turned loose to graze, it is only necessary to picket the bell mare, for the mules will all graze around and never lose sight of her. A thief needs to get away only with the bell mare and all the mules will follow. A case once occurred in which the bell mare broke her picket rope on a stormy night and wandered off, followed by all the mules. She fell, broke a leg, and perished in the storm. When found by the party several days afterward, the dead mare was surrounded by all the mules, and they were dying of hunger when, by wandering only a short distance away, they might have found plenty of food. All these, and others which might be mentioned, are obviously coltish traits.

Mules are infertile because ovules are not matured in the ovaries of the females, nor spermatozoa in the testes of the males. That is, there is no complete development of the essential element of sex in either case and consequently no correlation of that element with their psychological development. Therefore, psychologically, the mule remains a colt all its life, although in physical strength and general intelligence it is the equal and often the superior of either parent.

Smithsonian Institution, October 2, 1897.

Deformities after Fracture.—Deformity after unsuccessfully treated fractures may be prevented or relieved by refracturing the callus which unites the fragments. This is occasionally necessary in instances in which no treatment has been given. The bone is bent across the edge of a padded table or over the surgeon's knee, and after the band of union has been ruptured is treated as a recent accidental fracture. This may be done with success at the expiration of even six months, since the seat of fracture remains weaker than the rest of the bone for a long time.—Roberts, *Medical and Surgical Reporter*, October 31, 1896.

DIAGNOSIS BY BLOOD EXAMINATION.[1]

By H. W. FURNISS, M.D., Ph.D.,
INDIANAPOLIS.

That blood examinations have taken such a stride of late is due to the improvement in instruments for examination, differential stains, and consequent lessened labor and increased accuracy. About all that is necessary to be known about the blood in a given case can be ascertained in fifteen minutes, and since there are several diseases in which it is possible to make a positive diagnosis by blood examination alone, several others in which an examination will materially aid in diagnosis, others in which the negative result obtained aids us, to say nothing of the valuable assistance rendered in those cases in which we cannot communicate with the patient either because of stupidity, insanity, age, maligning, or unconsciousness—I deem it well worth even the busiest practitioner's time to avail himself of this aid to diagnosis, and particularly so in the case of fever, as there is no case on which a blood examination would not throw light.

To make a thorough examination of blood, it is necessary to find out the following facts: Number of red cells in a given quantity, which is usually a centimetre; number of white cells in the same; ratio of white to red; number of each kind of white cells; ratio to each other; size, shapes, peculiarities, and contents of cells; percentage of hæmoglobin; color value or relative amount of hæmoglobin per red cell; relative amount of fibrin; and finally, if any substance other than the above occurs, and if so, of what nature.

The methods of examining blood, its histology, preparation of specimens, stains used, etc., have been described from time to time in the medical journals and descriptions can be found also in any good book upon the subject, so I shall not take time to review them.

Naturally the first diseases that my paper would bring to your mind are anæmia and chlorosis, and rightly too, as no little of the diagnosis and prognosis can be told from a blood examination.

Anæmia is a diminution in red blood corpuscles, hæmoglobin, or both, and is independent of the color of the skin or the mucous membrane. The greater number of times it is impossible to tell pernicious anæmia from chlorosis except by blood examination. In the former you nearly always have decrease in the number of cells and a great alteration, decrease or increase, in size and form of the red corpuscles, the color value being high; while in chlorosis you may have decrease in red cells, but the principal thing is lack of cell hæmoglobin or color value. Then we may have megaloblasts in chlorosis, but normoblasts predominate; while the reverse is true of anæmia. True, we have fewer red cells in malignant disease, but then we nearly always have leucocytosis, which will help to distinguish; then normoblasts predominate in malignant disease, megaloblasts in anæmia.

Those diseases which do not cause leucocytosis but lessen corpuscles do not have megaloblasts or high color value, and leukæmia can always be made out by the greater number of myelocytes. In anæmia search carefully for nucleated corpuscles, for if any are present they will aid much in prognosis. The presence of megaloblasts with no other nucleated forms is a bad sign. It is the kind of nucleated corpuscles and not the number that is of interest—the ratio of megaloblasts to normoblasts that is important. Low color index and normal cells show improvement at the time; high color index is a bad sign.

In leukæmia the red cells are slightly diminished, the white markedly increased. About thirty per cent. of the white cells are myelocytes, and in lymphatic forms ninety per cent. are lymphocytes. Leukæmia is distinguished from Hodgkin's disease, which has the same symptoms, by the blood being normal in the early stages of the latter disease, and in the later stages not more than a slight anæmia existing.

It is possible by a blood count to diagnose shock of hemorrhage from that of concussion or compression, there being a marked decrease in red corpuscles in the former and none in the latter. In the same way internal hemorrhage can be told from peritonitis or obstruction, and the advisability of an operation after loss of blood can be safely told by estimation of the hæmoglobin, any percentage lower than thirty being a contraindication.

Again, it is possible by making a blood count to tell if one's patient has been in reality fasting, when if it is so there will be marked decrease in leucocytes; but it must be borne in mind that diseases of the stomach and small intestine may prevent leucocytosis. Then it must be remembered that pregnancy, violent exercise, cold baths, and massage may cause leucocytosis, but in each of these cases the condition of white cells remains about the same, only that the number is increased. We may expect leucocytosis to be present after hemorrhage in malignant disease and inflammation; and absent in malaria, measles, typhoid fever, and all forms of tuberculosis.

Typhoid fever is easily told by Widal's method or by Johnson's modification. The diagnosis depends upon the fact that blood or blood serum from a patient with typhoid will cause a drop of actively motile typhoid bacilli to cease motion and clump. Positive results are not always obtained, but they are nearly always. Acuteness or mildness of attack does not seem to have any appreciable difference on the clumping. Johnson's method consists in collecting a specimen of blood on a sterilized paper and allowing it to dry, thus permitting transportation—a great factor in municipal laboratory work. The dried blood is dissolved in a few drops of sterilized water, and a small portion of the solution added to a drop of bouillon containing actively motile bacilli. To make a success of the test, it is necessary to have a pure fresh culture of typhoid, and it has been observed that attenuated cultures work better than more virulent ones. The time necessary for the specimen to cause clumping should not exceed thirty minutes, and this clumping does not seem to be a killing of the bacilli, but just a paralyzing. It is said that this clumping cannot be caused by any other disease, yet it is quite necessary that the serum or blood should be considerably diluted, as it has been observed that sometimes healthy blood may cause this reaction, while typhoid blood diluted one to thirty will produce it.

Pneumonia is distinguished from typhoid, malaria, or plain influenza, when only symptoms are present and no physical signs, by the marked leucocytosis of the first-named disease. There is no means of diagnosing pneumonia from capillary bronchitis. In pneumonia there is always a marked fibrin network. So far as prognosis goes, the absence of leucocytosis is always an unfavorable sign, unless the case is of the mildest kind, while its presence leaves the matter in doubt, though favorable for recovery.

Septicæmia can be diagnosed by bacteriological examination of the blood; rheumatism and diphtheria cannot be told; and the grippe, according to Cannon, can be diagnosed by finding the specific microorganism in stained specimens of the blood.

Scarlet fever is distinguished from measles, in that the latter never has leucocytosis, while the former always has. In scarlet fever eosinophiles are absent in bad cases and increased in favorable cases.

Appendicitis cannot be told from pus tubes by exam-

[1] Abstract of paper read before the Marion County Medical Society, February 23, 1897, and the Indiana State Medical Society, Terre Haute, May 20, 1897.

ination of the blood, but can be told from colic, constipation, floating kidney, ovarian or pelvic neuralgia, gall stone and renal colic, if uncomplicated, because of the leucocytosis in the former and the lack of it in all other cases.

Cholera can be diagnosed in much the same way as typhoid fever, blood from a cholera patient causing a cessation of motion of cholera germs.

In peritonitis we have marked leucocytosis and increase in fibrin network, but there is no leucocytosis in tuberculous peritonitis, and it may thus be diagnosed.

Pericarditis with effusion can be told from hypertrophy or dilatation on account of the marked leucocytosis in the former case.

In meningitis we always have leucocytosis, while in no other form of intracranial disease except abscess and apoplexy do we have this phenomenon. On account of the always-present leucocytosis, meningitis can be told from typhoid, which it simulates, but cannot be told by blood examination from pneumonia.

Justus claims to be able to diagnose syphilis before the secondary symptoms have appeared. He first estimates the percentage of hæmoglobin, then gives inunction or injection of mercury, and finds that the hæmoglobin falls from ten to twenty per cent. in a day, which he attributes to the action of the mercury on the weaker blood cells. After a few days this marked diminution is followed by a gradual rise, and soon the percentage of hæmoglobin is higher than it was before. He claims that syphilis is the only disease in which the facts stated occur. Blood examinations otherwise are negative, except so far as indicating the severity of the affection, large numbers of young white cells and small percentage of hæmoglobin being diagnostic of severer cases. Cases having myelocytes are serious, while we look for leucocytosis after the primary stage.

According to Bremmer, of St. Louis, it is possible to diagnose diabetes by blood examination long before it could otherwise be told. His method is simple. He heats two blood films, one normal and the other of suspected blood, in a hot-air sterilizer for six or seven minutes, at a temperature of 135° C. He then allows the specimens to cool, and when cold he exposes the two to a one-per-cent. aqueous solution of Congo red or methyl blue for two minutes, when the normal blood will be stained red or blue according to the color used, and the other if diabetic will resist the action of the stain.

In purpura hæmorrhagica, hæmophilia, and scurvy, diseases in which you would expect to learn a great deal from blood examination, there is little or no characteristic change.

In examining the blood for malaria, it is best to take the specimen before or after the chill, as then the plasmodium is larger and is pigmented. It does not take much skill to find the plasmodium, provided you know what you are looking for and are patient and painstaking; and once you find it, it will be quite easy in the future to recognize it. Staining has its advantages, as by it it is easier to see the organism and one can examine it at one's leisure; also there is not the danger of confusing the plasmodium with other things found in the blood. The best stain to use is Phlen's, which is a combination of eosin dissolved in alcohol, and methylene blue. The blue stains the plasmodium itself, and the corpuscular substance is in contrast stained pink. In all cases of suspected malaria the blood should be examined, as clinical symptoms alone often warrant a diagnosis of malaria when tuberculosis, syphilis, septic infection, or something else is the true cause of the symptoms.

Pleurisy may be diagnosed from empyema, pneumonia, and malignant lung trouble, and cyst of kidney from perinephritic abscess, by the absence of leucocytosis.

Holmes, of Denver, claims to be able to diagnose tuberculosis, even in its earliest stages, by blood examination, even when it is impossible to tell it either by physical signs or sputum examination. He bases his theory upon the assertion that each individual has a biological prototype in the leucocytes of his own blood. He further claims the following characteristics of tuberculous blood: "Marked deviation from normal percentage of all varieties of leucocytes. Great decrease in percentage of small lymphocytes. Usually marked increase in percentage of large lymphocytes. Many giant lymphocytes with irregular contour and protruding globules of hyaloplasm. Eosinophile cells absent or few in number only in severe cases. Myelocytes occasionally present. Marked cell disintegration. Many groups of *débris* from disintegrating leucocytes. Phagocytes with indistinct cell contour and granules few in number, poorly stained, and scattering. Marked irregularity in size and appearance of phagocytes, dwarf phagocytes as small as small lymphocytes, giant phagocytes double usual size, with five or more nuclei. Often a clear narrow and sharply defined ring separating the nucleus from the cell body in small and large lymphocytes. Phagocytes with granules taking a basophilic tint, evidence of approaching dissolution. Grouping together of a large number of phagocytes observed before dissolution. Very little disintegration of red cells."

Finally, the examination of blood in post-operative pyrexia is of value to determine if pus is present, as with pus there is always leucocytosis.

MEDICAL AND SURGICAL ICONOCLASM.

By MARVIN L. GRAVES, M.A., M.D.,

WACO, TEXAS.

Art admits no model but perfection. Science permits no result but truth. Medicine acknowledges its empiricism; surgery its experimentalism. Evolution and revolution have touched and influenced every thought known to man. Scepticism has been the point of origin of many truths. Agnosticism has been the invariable and essential accompaniment of many facts, finally demonstrated and accepted. Doubt, question, and negation have resulted in greater progress than ignorant affirmation or blind belief ever accomplished. Interrogation and investigation will never injure truth nor aid error. In seeking to draw your attention to iconoclasm and its always preceding or accompanying scepticism or agnosticism, no reference whatever is made to the use of these terms in religion. They have their practical application to the creed and practice of our profession. Iconoclasm literally means the smashing of idols or images, and it denotes either partial or complete destruction of the object together with the accompanying superstition or fanaticism attending its existence. Medical and surgical iconoclasm means the destruction of false theories and wrong and harmful practice in medicine and surgery. It means that the cold, critical, searching flashlight of experiment and investigation will dethrone error and enthrone truth. It means the exposure of all forms of sham and deception, accidental or intentional. It means the unmasking of charlatanry, whether inside or outside the regular profession. It means the total rejection of harmful doctrine and evil practice, wheresoever found. It means that the insanities of spiritualism, the frauds of Christian science, and the hollow pretences of vitapathy and magnetism, and all other medical and surgical isms and pathies not

founded on truth and supported by reason, shall fall beneath the guillotine of an art that is skilful and of a science that is inexorable. But iconoclasm is not merely destructive; it is also constructive by reflex action. It is creative by reaction. It may tear down, but it will also build up. The one may be radical, the other may be conservative, yet when the pendulum ceases from its excessive oscillations to and fro it is almost certain it will then traverse an arc of right and safety. Life in nature is said to come through death. Sacred Writ hath taught this great lesson in the "corn of wheat." Certain it is that in the creative chemistry of nature and the artificial laboratory there is a change, a transformation, if not an actual destruction of one or more elements in the formation of another. Through this process of destruction a newer and perchance a better life is born. Theories and doctrines have passed unquestioned from century to century, till some earnest, honest sceptic began to doubt, then question, then deny—

> "Till out of the darkness future brightness is born,
> As after the night comes the sunrise of morn."

Gravitation and the revolution of the heavenly bodies never met their correct explanation till Newton and Kepler, the iconoclasts of astronomy, disproved a host of false theories, smashed the idols of error, and established truth.

The pivotal point of modern progress is the "origin of species" and Charles Darwin's iconoclasm of hoary-headed errors. The inspiration of the new philosophy was born in the death agonies of the old. What may be said of the fanciful and foolish notions of the circulation of the blood, of the different functions of nerve and nerve cells, of the pathology of disease, before Harvey and Bell and Bernard and Charcot, mighty men of genius, medical and surgical iconoclasts, whose scientific minds revolted at error and never failed or faltered till modern physiology and pathology were established on accurate foundations? Who but an iconoclast like Lord Lister disputed the darkest of surgical heathenisms and illuminated the entire field of surgery by asepsis and antisepsis? Who but iconoclast Koch rejected the erroneous doctrines of tuberculosis and cholera, and after years of patient uncomplaining toil demonstrated their germal origin and erected a triumphal arch under which shall yet pass successful treatment? Who but Marion Sims doubted and denied the older practice of gynæcology and revolutionized this branch of surgery throughout the civilized world? Who but Jenner and Pasteur tore aside the cobwebs of ignorance and superstition from small-pox and hydrophobia, and gave to suffering, terror-stricken humanity a hope and a practice that have saved multitudes of lives? In the reactionary construction which follows destruction, it matters not whether each reformer or revolutionist himself established the complete truth. He may have only blazed the path and destroyed monster obstacles, and later investigators, led on by his flickering, perhaps feeble, but never-dying light, have solved the problems and blessed humanity. It was not necessary for Semmelweiss to live to see every obstetrician acknowledge that puerperal fever was a septic disease and due to infection by the surgeon at delivery. It was not necessary for the immortal Long to live to see anæsthesia practised in every hamlet on the globe and agonizing pain relieved under its blessing. It was necessary that, amid ridicule and derision, they gave to the world a new thought and improved practice. Nowhere in all the realm of science and art have scepticism and agnosticism been more truly the stepping-stones and starting-points of progress—real, true, beneficent advance—than in medicine and surgery. In the very nature of our art empiricism and experimentation were necessary.

Exactitude was impossible, perfection unattainable, when knowledge was minus and ignorance plus—when so many factors, as heredity, season, climate, age, constitution, and incomplete pharmacy, blocked the way. Out of all these difficulties patient investigation has tabulated results, until to-day etiology, physiology, and pathology have much of certainty, and diagnosis, prognosis, and treatment are growing more exact and more certain. But the mountain top has not yet been reached. Many fogs and sloughs and quagmires still remain. Modern medical science is throwing the searchlight full upon some modern fads and fancies, and exposing some deep-rooted fallacies. Of all men, the physician of to-day is the most sceptical. It is only after the most thorough trial and careful examination that he gives his approval to the theory of *post hoc ergo propter hoc*. He waits, he watches, and tries each new remedy or operation suggested or doctrine expounded, before he adds his sanction or expresses his rejection. Everything is rigidly tested; eclecticism in its broadest and truest interpretation demands it. Humanity, the victim or grateful beneficiary, demands it. No great man's *ipse dixit* will now make tuberculin cure consumption or antitoxin destroy diphtheria.

Let me point out to you some of the dangers that will threaten us if we lose this spirit of beneficent iconoclasm in our professional work. We do not record accurately and fully our cases in detail. We do not take time to study fully the disease we treat. We do not examine each case and note all signs and symptoms. We do not group, tabulate, and analyze series of cases, and thus get at correct conclusions. We do not report or write up our cases and subject them to the kindly criticism and discussion of the profession. Our haste and inaccurate style are illustrated in the following: How many of us, called to a man suffering intense pain, ever stop to examine him carefully before shooting a hypodermic of morphine into his arm? Admit the immediate necessity of relief—how many of us leave the house when pain has ceased without further effort to find out what really was the matter? How often, when asked to prescribe for piles, we write a prescription without even requesting an examination or knowing the condition, and later find the patient in the hands of an advertising quack, being cured of ulcer in the rectum? How frequently complaint of headache receives a routine prescription without question, when uræmic toxæmia or uterine disorders are the offenders? How often does a uric-acid storm or a bilious attack find itself labelled malarial fever and cured in twelve hours with calomel and quinine and arsenic? How frequently does a slight dermatitis, insignificant in nature and effect, flame out a violent erysipelas and require all the skill of Dr. Blowhard to cure it in two days? How often, oh! how often is typhoid fever turned into febricula and chased off the field of action in four days by the specific treatment of Dr. Greatman? How frequently is an ordinary bronchitis with engorged liver and pain in the side kept under dim gaslight and slippered tread and whispered consultation for two weeks; or, on the other hand, a terrible pneumonia throttled in twenty-four hours by the heroic treatment of Dr. Allgas?

Let not criticism assume a personal form or question smite an individual. It matters but little that the full value of hydrotherapy has been established by hydropathists as a clique. It matters but little that simpler methods and smaller doses have been the results of homœopathy as a sect. It matters but little that many new and reliable drugs have been introduced by eclecticism as a faction. It matters still less that spiritualism and Christian science as creeds have estab-

lished hypnotism and suggestive therapeutics. But it matters much that whatsoever doctrine advanced shall be truth; that whatsoever remedy offered shall be good. It matters much that education is getting broader and more catholic; that art demands skill, science commands exactness. It matters much that physicians are learning that they can no longer diagnose a simple urethritis as a virulent gonorrhœa, and cure the patient in two days; that the victim of a cough can no longer be called consumptive and cured with a patent consumption cure—when microscopical analysis of the former shows absolutely no gonococci, and laryngeal exploration of the latter shows a polyp easily removed. It matters much that dropsy can no longer be attributed to jaundice, but under the blaze of science reveals its cardiac, renal, hepatic, or abdominal origin. It matters much that typhoid fever can no longer be purged with calomel and tortured with quinine, when proper nourishment and careful nursing will tide the patient through. It matters much that everything is no longer congestion and the stomach no longer a swilltub into which may be poured all the refuse of the pharmacists. It matters much that our doctors are once again learning that water properly applied, the stomach wisely preserved, nutrition supported, and vitality stimulated, will save many a life when polypharmacy will dig many a grave. It matters much that nervous exhaustion is now not always due to overwork and loss of sleep, when we know the patient never worked three hours a day and sleeps nine out of twenty-four. It matters much that thirty grains of calomel are no longer specific for constipation and torpid liver, and orange blossoms can no longer be applied to the vagina for endometritis. It matters much that poultices are no longer applied to ruptured tubal pregnancies and that iodine is no longer painted over large pelvic abscesses. It matters much that a little uterine inertia is no longer the occasion for the application of the long forceps and the combined strength of Hercules and Samson to tear a child's head through a safe passage with tremendous velocity, when thirty grains of quinine or two ounces of sugar will deliver the babe safely at the end of forty minutes and still leave the mother a cervix, a urethra, and a perineum. It matters much that public sentiment and professional conscience no longer allow every tyro to open bellies indiscriminately in search of ovaries with imaginary inflammation or tumors of doubtful existence.

Then, all hail iconoclasm in its active destruction and its reactionary construction of safe practice and legitimate surgery!

600 Austin Avenue.

Sprains and their Treatment.—Graham defines a sprain as a wrench or twist of a joint; a sudden, partial displacement of two articulating surfaces, followed by immediate replacement. The symptoms include pain, swelling, discoloration, and usually heat, with impaired mobility. The diagnosis may be obscured by swelling, which may conceal also a fracture of bone. Whatever will quickly reduce the heat, the pain, and the swelling—such as massage, snug bandaging, and an elevated position of the joint—will proportionately make the diagnosis easier. The means just mentioned are therefore valuable not only for diagnosis, but also for treatment; and their use in many cases of sprains of all degrees of severity shows that recovery follows in one-third of the time required under absolute rest and fixed dressings without massage. Even the condition of a sprain involving a joint previously weakened by malignant disease may be rapidly ameliorated by massage, and useful motion be gained before amputation. *Boston Medical and Surgical Journal*, June 17 and 24, 1897.

Progress of Medical Science.

Acute Partial Enterocele.—Upon this subject Stahl (*Journal of the American Medical Association*, October 2, 1897, p. 683) reaches the following conclusions: 1. Acute partial enterocele does occur. 2. The symptoms of this condition are of a milder type than those of an acute complete enterocele; if it is strangulated, the vomiting is not stercoraceous and constipation not absolute. Exceptionally the reaction is so slight that the condition continues unrecognized. 3. Because of mildness of symptoms, smallness of size, and tendency to disappear, it requires most careful differentiation. 4. Acute partial enterocele is to be especially differentiated in its early forms from a large inguinal gland; in its later or inflammatory form from suppurative adenitis. 5. The acute form of partial enterocele, if not relieved, either induces the usual reactionary changes of an acute hernia or it is converted gradually into the chronic form of partial enterocele. 6. The treatment consists in reduction by taxis or in herniotomy.

Foot-and-Mouth Disease.—Loeffler and Frosch (*Deutsche medicinische Wochenschrift*, September 23, 1897, p. 617), constituting a commission appointed to investigate foot-and-mouth disease, report the following summary of the conclusions reached by them: (1) All of the bacteria hitherto described as the exciting cause of this disease have been accidental associations. The disease can be induced by inoculation with sterile lymph obtained from the vesicles, which contains morphotic elements of various kind. Protozoa have not been demonstrated as the causative agents. (2) Beef and swine have been also shown experimentally to be especially susceptible to the disease. Sheep and goats could not be infected artificially at first, as well as dogs, rabbits, guinea-pigs, ordinary mice, field-mice, and fowl. (3) The most certain mode of infection consists in the injection into the circulation of lymph obtained from vesicles. Infection could be induced also by injection of such lymph into the abdominal cavity and into the muscles, as well as by its introduction into the mucous membrane of the mouth previously injured by puncture. Uncertain results followed subcutaneous and cutaneous inoculation. In animals inoculated by intravenous injection vesicles appeared first in the mouth, and in milch cows upon the udders, after the lapse of from one to three days—in accordance with the amount and virulence of the lymph—in conjunction with febrile manifestations, and one or two days later vesicles appeared, first upon the extremities. Both sets of vesicles are thus to be attributed to virus circulating in the blood and not to direct infection from the skin. With the development of the vesicles the virus disappears from the circulation. 4. To effect inoculation with certainty, one-five-thousandth of a cubic centimetre of fresh lymph was sufficient. Smaller quantities up to one-twenty-thousandth cubic centimetre were uncertain in their effects, and still smaller quantities were innocuous. (5) The lymph was rendered innocuous when heated to 37° C. for twelve hours, or to 70° C. for half an hour, and also on drying for twenty-four hours at summer temperature. Preserved in refrigerators, the lymph inclosed within capillary tubes retained its virulence for fourteen days, at times even longer. Individual germs proved capable of continued existence for eight or nine weeks. Large quantities of lymph were necessary to induce infection. (6) In opposition to prevailing views it was demonstrated that immunity was conferred upon infected animals two or three weeks after recovery from an attack. On the one hand some animals are natu-

rally immune, while on the other hand others are extremely susceptible. The latter are not rendered immune by a single attack, but more fully so by a second. The blood of immunized animals contains substances which when mixed with fresh lymph seem capable of neutralizing the effects of the latter in susceptible animals. (7) Beef and swine can be immunized artificially by means of injections of lymph warmed until its infectiousness is removed, as well as by injection of mixtures of lymph and blood from immune animals. The majority of animals were rendered immune by a single injection, which apparently induced no bad effects. (8) It thus appears scientifically demonstrated that foot-and-mouth disease can be successfully treated by means of protective inoculation.

Successful Treatment of a Large Aneurism of the Aorta by Increasing Artificially the Coagulability of the Blood. — At a recent meeting of the Académie de Médecine, Lancereaux (*Deutsche medicinische Wochenschrift*, August 12, 1897) reported the case of a man with an aneurism of the ascending aorta, as large as a child's head, which had eroded a portion of the sternum and the cartilages of several ribs, was palpable immediately beneath the skin, and appeared about to rupture. Upon the basis of previous experiments upon animals, an attempt was made by means of injections of gelatin to increase the coagulability of the blood, in order to augment the formation of clots along the wall of the sac. Accordingly injections were made in the gluteal region, until in the course of two months the amount of gelatin in solution injected equalled more than two quarts. In the mean time the tumor became firmer and distinctly reduced in size, although some pulsation continued to be transmitted. The severe subjective discomfort present at first wholly disappeared, so that the patient declined to continue the treatment longer.

The Treatment of Tympanites. — Porter (*Medical News*, July 31, 1897, p. 134) contends that intra-intestinal tympanites often causes death in patients suffering from abdominal and pelvic disease, and that it may do so also in cases in which the abdominal and pelvic organs are free from disease. Tympanites occurring in the course of any serious illness should be considered a symptom of ill omen, and measures for its relief should be promptly instituted. If relief fails to attend the use of cathartics, posture, enemata, and the rectal tube, cœliotomy and incision of the bowel should be undertaken without delay. In cases of general peritonitis and obstruction of the bowel, no trial should be made of other methods, but cœliotomy and incision of the bowel should be undertaken as soon as the diagnosis is made. Puncture of the bowel should be practised only in cases in which the patient is *in extremis*, and then only in cases—such as those of typhoid fever without perforation, pneumonia, etc. —which present no other indication for cœliotomy than the tympanites itself.

The Prophylactic Utility of the Diphtheria Antitoxin. — The Roman correspondent of the *British Medical Journal* cites the report of an epidemic of diphtheria in the town of Baricella, in the province of Bologna, the progress of which was arrested by preventive injections of the diphtheria antitoxin. The outbreak developed among a population of fifty-five hundred persons, exposed to the worst possible hygienic and dietetic conditions. Fifty-eight cases occurred in the course of a few months. Of this number fifty-four were treated with the antitoxin of diphtheria, with five deaths—a mortality of 8.6 per cent. The usual prophylactic measures, *i.e.*, isolation, disinfection, closure of the schools, etc., failed to bring the epidemic to an end. Recourse was therefore had to preventive inoculations on a large scale, four-fifths of the children of the poor, between one and twelve years of age, receiving the treatment. At once new cases failed to appear among the vaccinated children, although they continued to develop with their previous frequency among those not subjected to the prophylactic treatment; and the epidemic was soon brought to an end.

The Treatment of Lupus Vulgaris with the New Tuberculin.—Morris and Whitfield report, in the *British Medical Journal* of July 24, 1897, six cases of lupus vulgaris submitted to treatment by means of injections of the new tuberculin of Koch, and summarize as follows the effects, in the order in which they were observed: A diminution of the surrounding halo of redness in those cases in which this had been present to a marked degree before the commencement of the treatment; in cases in which there were simply yellowish-brown nodules in a white scar, the injections produced no visible effect at this stage. The next change noticed was a slight depression in the centre of the nodules, leading to wrinkling and later to desquamation of the cuticle. Then there occurred a steady healing of all ulcerated surfaces, and slow subsidence of the previously permanent œdema of the lips, ears, etc. In two cases actual disappearance of the characteristic lupus nodules was observed. In other cases there was distinct shrinking of nodules, with diminution in the scaling of the surface. Another effect of the injections was the softening and flattening of pre-existing scars. In no case was there the slightest progress after the institution of the treatment. In the sequence of the injections there was at first little or no reaction, although in some cases a feeling of heaviness and drowsiness was complained of. When the larger doses were reached there was considerable febrile disturbance, sometimes with headache and pains in the limbs, and even some trouble in breathing, and a general feeling of depression, with broken sleep. Locally the erythema was generally increased, and the whole affected area, including even old-standing cicatricial tissue, was swollen. In two cases in which there were sound scars, probably from previous lupus, no reaction was observed in the scars. The phenomena of reaction quickly disappeared and were followed by a better feeling on the part of the patients. On the whole, the opinion is expressed that the local effects of the new tuberculin in the cases of lupus vulgaris in which it was employed were uniformly good, in some cases distinctly brilliant. The constitutional disturbance was in no sense severe and always of a transitory character. As far as could be judged, the injections did no harm.

Multiple Neuritis Following Influenza. — Allyn, writing in the *Journal of the American Medical Association*, July 24, 1897, reports several cases of multiple neuritis following attacks of influenza, and from these and a study of the literature of the subject he reaches the conclusion that influenza, like other infectious diseases, may be followed by neuritis and multiple neuritis. One sex does not seem to be more liable to this complication than the other. It occurs most frequently in persons between the twenty-fifth and forty-fifth years, and appears during convalescence in a few days or two or three weeks after the attack of influenza has subsided. It may present sensory, motor, vasomotor, or trophic symptoms, or all combined; but sensory and vasomotor symptoms are more prominent than in diphtheria and some other causes of multiple neuritis. In the great majority of cases recovery ensues, both as regards restoration of function and power, as well as regards life. Recovery does not

usually take place in less time than four weeks, and may be delayed for months. Treatment should consist first in absolute rest in bed. Anodynes must be given in sufficient doses to relieve pain, when that is a prominent symptom. Morphine hypodermically may be necessary, but may be often replaced by codeine. The antipyretic anodynes are insufficient in safe doses if the patient has pains for many days. Cinchonidine salicylate is distinctly valuable, especially when the pain is not of the greatest severity. At a later stage potassium iodide and mercuric chloride in small doses are helpful. When the pain is seated in an extremity firm pressure with a flannel bandage yields great comfort. Blisters over the painful nerve trunks when they are superficial are also valuable in relieving pain. Close watch must be kept on the action of the heart and the character of the breathing. In most of the fatal cases death results through paralysis of the diaphragm. The closest attention must be given throughout the course of the case to the nutrition of the patient and to the condition of the skin, especially over portions of the body exposed to pressure. As far as possible the stomach should be reserved for food. Medicines in these cases act better when given hypodermically, and the stomach is less likely to be deranged. This caution applies especially to the giving of anodynes.

The Treatment of Scleroderma.—Philippsohn (*Deutsche medicinische Wochenschrift*, August 12, 1897) reports the successful treatment of a case of scleroderma by Bülau with sodium salicylate, in doses of fifteen grains three or four times daily, and reports two cases of the same disease also successfully treated with salol in doses of seven and one-half grains three or four times daily. From this experience it is concluded that scleroderma is, with respect to the induration of the skin, capable of improvement and cure by means of salicylic acid. Early administration would be likely to prevent deformity and secondary atrophy. The best form in which to administer salicylic acid is that of the phenyl or ether. Salol, which is also capable of controlling the itching, can be taken for long periods of time without deranging the digestion. The daily dose is from thirty to forty-five grains. If after the disease has existed for some time shortening of muscles and tendons or stiffness of joints takes place, this must be overcome by systematically directed gymnastic exercises.

A Fatal Case of Addison's Disease in a Young Girl.—Bury reports in *The Lancet* of June 19, 1897, the case of a girl, thirteen years old, who had always been a delicate child, tiring easily and being constantly sleepy. As an infant she had been treated for rickets and diarrhœa. She had never had a severe fall or received any bodily injury. At the age of eleven years, after a stay of several weeks in the country, her skin became dark colored, as if sunburned, but in the course of a few weeks her natural color was restored. The existing illness had begun about a year previously, with symptoms of gastric disturbance—discomfort after food, nausea, and vomiting. She suffered also from headache, and on three occasions had fainted. In the course of a few weeks a change in the color of the skin was noticed, and it gradually became darker. For two months there had been daily vomiting and weakness had become marked. The girl was thin and of slender build, and had obviously wasted. All parts of the body were of a brown color, like that of a mulatto. The tint varied in depth in different parts, but the transition between a dark brown and a light brown was everywhere quite gradual. The bronzing was most intense at the back of the neck, on the dorsum of the hands, on the lower part of the abdomen, and over the knees; and least intense on the palms of the hands, the soles of the feet, and over the calves of the legs. No pigmented moles could be found. The nails were of normal color and the conjunctivæ were pearly white. A faint, patchy pigmentation was seen on the mucous membrane of the lips and the inside of the mouth. The tongue was free from discoloration. No enlarged glands could be found, and no abnormality could be detected on careful physical examination of the chest and abdomen. There was complaint of pain in the epigastrium, which was aggravated by the taking of food; and there was slight tenderness on pressure in each lumbar region, palpation setting up spasm of the abdominal muscles. The pulse was 96, regular, and feeble. The urine presented no abnormality. There were no paralysis, and no alteration of cutaneous sensibility. The knee jerks were increased and the wrist jerks appeared unduly irritable. No ankle clonus could be elicited. The superficial epigastric, abdominal, and plantar reflexes were exaggerated. Varied treatment was employed, including adrenal extract in one form or other, but progressive deterioration took place, and death followed a convulsion succeeded by coma. Upon post-mortem examination, in addition to congestion of the cerebral meninges, hemorrhages beneath the visceral layer of the pericardium, slight pleural adhesions on the left side of the chest, and diminished size of the thyroid gland, the adrenals were found enlarged and firm and adherent to surrounding tissues. Upon microscopic study the latter presented histologic changes of tuberculosis. The semilunar ganglion and the left great splanchnic nerve exhibited no pathologic alteration.

Traumatic Rupture of the Duodenum, with Survival for Sixteen Hours.—Close reports the case of a boy, thirteen years old, who had been kicked by a horse, and when seen twelve hours later was found lying in bed with the hip-joints slightly flexed and the face pale and anxious. There was complaint of some pain in the lower part of the abdomen, which was slightly distended and very tender. There was no visible bruise or external wound. The abdominal muscles were rigidly contracted and free manipulation could not be made. The percussion note was quite dull over the whole of the lower part of the abdomen and in the left flank, while there was a band of tympanitic resonance below the costal margin and ensiform cartilage; and in the right flank also the note was tympanitic in character. The temperature in the mouth was 102.5° F. The pulse was 140, rather small, but not thready. Consciousness was preserved and the patient was able to give a connected account of the accident. It was learned that the boy walked for some distance after the accident. Subsequently he was taken home, and after the application of hot flannels he so far recovered that he was able to get about for some hours, and walked upstairs and downstairs. Later vomiting took place. Clear urine, free from blood, was obtained by catheterization. The conclusion was reached that a rupture of the intestine had taken place, and cœliotomy was decided upon, but before the operation could be begun the patient was moribund, the abdomen becoming greatly distended. Upon post-mortem examination the peritoneum was found to contain about two pints of cloudy fluid mixed with partially digested food. The intestines were much reddened and coated with flakes of recent lymph. On turning back the omentum and coils of small intestine, a rent was found in the second part of the duodenum, from which the chyme was escaping. The opening was large enough to admit four fingers, and was four and one-half inches from the pyloric orifice. —*The Lancet*, July 17, 1897.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, November 6, 1897.

REMEDIES ANCIENT AND MODERN.

PRESENT-DAY medicine discards more and more the use of drugs. It puts its trust rather in natural agencies and recognizes the fact that each person possesses a separate individuality, instead of, as in the old days, lumping people together and prescribing to them the same drugs, without considering their differing temperaments or dispositions. An intelligent doctor will study the character and temperament of his patient, so as to act on the body through the influence of the mind. In a few words, the tendency of modern practice is to treatment by suggestion. The doctor therefore, should be a many-sided man, of a wide and warm nature, with active sympathies, and possessed of much tact. We all know that contact with a man of this type in many instances does a sick person more good than a prescription. Faith goes a long way, and the battle against disease is often half won when we resolve in our own minds to get well. In the face of this condition of things it is both curious and interesting to read a description of some of the old-time remedies. In a work that appeared in Frankfort in 1701, entitled "A Good and Careful Medicus," by Dr. Johann Helffrich Jüngken, an account of some of the remedies in use at that period is given. For instance, it is stated that "sores of the lips could be cured if the oil or fat which runs out when a wooden spoon is held over the fire was applied to the sores." For the cure of jaundice the advice is tendered "to fasten a live fish, preferably the 'schleye,' around the body or against the soles of the feet, and let it die there." For hydrocele, applications of a mixture of goat manure, crushed snails, powdered sulphur, and kümmel were made. The nastier the mixtures were, the more efficacious were they esteemed. Another alteration for the better that has been made in administering drugs is that they are not, as formerly, given in excessive combination, but are much more frequently prescribed singly.

Yet great as has been the advance in medical treatment and in the preparation and prescribing of drugs, we are nowadays rather too apt to plume ourselves on our superior knowledge, and to regard the pioneers in medicine with a pitying contempt. It should be remembered that the Egyptians, Greeks, and Romans had a very fair acquaintance with both medicine and surgery, and especially with drugs and their properties. Most of the drugs on which we chiefly rely date very far back. Nearly all those most commonly in use were known thousands of years ago. Castor oil and rhubarb were prescribed by the old Arabians, ergot was used in parturition by the peasants of Germany hundreds of years ago, male fern in tapeworm by the early Greeks and Romans. Mercury has been the specific for syphilis almost from time immemorial, and the list can be indefinitely lengthened. The most ancient pharmacopœia known was found between the legs of a mummy about 1500 B.C., and even the principles of modern treatment were practised by Asclepiades of Brussa, who was a sceptic in the use of drugs, and declared "that the cure must be effected by the physician, who must do this safely, quickly, and pleasantly."

History has a tendency to repeat itself. It is probable, too, that the people who inhabit this earth in a hundred years from now will regard our methods of treatment as antiquated and crude, or possibly as superfluous. The prophecy that in the course of time many diseases will be altogether stamped out is not too bold a one to make. Prevention, not cure, will be the motto of the future.

THE SIGNIFICANCE OF INEQUALITY OF THE PUPILS IN CASES OF CARCINOMA OF THE ŒSOPHAGUS.

THE occurrence of inequality of the pupils in conjunction with tumors of the œsophagus is not at all rare, and is to be attributed sometimes to involvement of the sympathetic nerve, sometimes to involvement of the anterior root of the first dorsal nerve, in which pass the oculo-pupillary fibres of the sympathetic. In the latter event there exists, in addition to atrophic palsy of the small muscles of the hand, with characteristic sensory derangement, narrowing of the corresponding pupil and palpebral fissure, with retraction of the eyeball and sluggish reaction of the pupil to light. Inequality of the pupils, with narrowing of the palpebral fissure and retraction of the eyeball, having been observed at the clinic of Professor Eichhorst at the University of Zurich, in a case of carcinoma of the œsophagus, attention was directed to the frequency of the association, and the results are detailed by Hitzig in the *Deutsche medicinische Wochenschrift*, No. 36, 1897. In the course of the year following the original observation, inequality of the pupils was found in four of nine cases of carcinoma of the œsophagus. In twenty-seven earlier cases this peculiarity had been noted but once. In five of the cases the left pupil was contracted and there were no further oculo-pupillary or vasomotor manifestations. In the sixth case there had been also paralysis of the right recurrent laryngeal nerve, and the right pupil and palpebral fissure were smaller than the left, and the eyeball was somewhat retracted. There was, however, no atrophy of the muscles of the right hand. Subsequently there was also paresis of the left recurrent laryngeal nerve. The post-mortem examination disclosed, in addition

to carcinoma of the œsophagus, at the same level, to the right of the œsophagus, a large carcinomatous lymphatic gland involving the vessels and nerves.

IDIOPATHIC SALIVATION.

Salivation may arise from a variety of causes—some local, some remote. In some instances an etiologic factor is not obvious. Among the local causes are inflammatory processes in and about the mouth and its glandular appendages; for instance, stomatitis, glossitis, gingivitis, pharyngitis, etc. Mercurial and other forms of metallic intoxication, such as plumbism and poisoning with antimony, may likewise be placed in this category. Among the remote influences related to salivation, some of which are constitutional and others reflex, may be enumerated gastro-intestinal disorders, nausea, vomiting, gastralgia, pregnancy, suppression of menstruation, hysteria, mania, epilepsy, hydrophobia. Excessive discharge of saliva sometimes occurs as a critical manifestation in the course or at the close of attacks of pneumonia, dysentery, septic intoxication, typhoid fever. It may also take place with the disappearance of a pre-existing leucorrhœa or œdematous state. Jaborandi or its alkaloid, pilocarpine, is almost the only drug directly capable of inducing excessive salivary secretion. Finally, there is a small number of cases in which no cause for the morbid condition can be ascertained. In these the disorder is designated essential or idiopathic, but such a distinction can be considered only tentative, to be supplanted by a more accurate and distinctive one when the expansion of our knowledge shall disclose the previously hidden cause.

In a recent communication upon this subject, Jordan (*Birmingham Medical Review*, September, 1897, p. 173) has reported two interesting cases of so-called idiopathic salivation occurring in children. In one the patient was a boy, four years old, who came under observation on account of constant dribbling of saliva from the mouth. The child's clothing for some distance below his neck was thoroughly soaked. It was stated that he had always dribbled, very much so during dentition. The dribbling continued at night, so that the pillow was wet, but to a less extent, and the amount of saliva that escaped varied from time to time. The boy appeared quite happy, and but for the salivation perfectly healthy. He was said to be in good health, to eat well, and have no digestive trouble, but to be always thirsty. He used ordinary diet and was very fond of porridge. He was intelligent for his age and talked plainly. Examination disclosed no latent mischief or defect, general or local. The mucous membrane of the mouth was healthy; the left tonsil was perhaps slightly enlarged; and of the teeth, which were cut normally, the lower premolars were already decaying. Four other children in the family were in good health and displayed no tendency to salivation.

Three months later another boy, aged two and one-half years, presented himself, giving a history almost identical with that detailed. This child too had dribbled very much during dentition, which began when he was four months old, and was completed eight months later. The dribbling continued, but received little attention until the child was two years old. From this time it had grown gradually worse, although it varied in degree. The clothing was saturated. At one time the dribbling had continued through the night. The general health was said to be good except for attacks of tonsillitis. This child also had fed much on porridge. His teeth and the mucous membrane of the mouth were in a healthy state, but the tonsils, especially the left, were much hypertrophied. No other lesion of any sort was discovered on examination. The boy was intelligent, although he did not speak plainly.

The condition described appears to be a rare one. Finlayson has reported a case in which salivation appeared rather suddenly in a child at the age of six years, and Bohn has contributed an article on the subject to Gerhardt's "Handbuch der Kinderkrankheiten," Bd. iv., Abth. 2. The disorder may set in in early life, during dentition, and continue indefinitely thereafter. In some cases it occurs for the most part only in the erect posture, ceasing, as a rule, during sleep. It may be diminished by emotions of the most varied kind. Iron has proved of undoubted influence in the treatment, but although anæmia was present in some cases this is not thought to be a cause of the disorder. The affection presents some features of a neurosis. The intermittent character of the salivation, its subordination to psychic influences, its tendency to abate with the development of the body or to yield to remedial drugs, point to a peculiar and isolated affection of the salivary-gland nerves in the developing organism of the child. How late in life the disorder may continue is a matter of uncertainty. The question arises: How far may the salivation be the result of an increased flow, and how far due to a failure to acquire the habit of automatically swallowing the saliva? In the presence of hypertrophied tonsils it is possible that as a result of difficulty in swallowing there may be a failure to acquire the habit of performing this act automatically.

A DISPENSARY NEEDED.

Not unduly to prolong the suspense, it should be stated in passing that we are not speaking of New York. In a recent number of the *North Carolina Medical Journal* the editorial department is devoted exclusively to a plea for the establishment of more dispensaries and hospitals in the South. The burden of caring for the sick poor in many regions now falls wholly upon the physician, who must often supply medicines besides giving his services and time, to say nothing of wear and tear to gig and horseshoe and perhaps pneumatic tire. There would appear to be a lack of "charity" in certain portions of our Southern States. The writer says: "In only three or four of the larger towns is there any effort being made to dispense medical aid to the poor from the public funds."

The good-natured doctor seems to accept the bur-

den placed upon him as a necessary part of his professional duties. If in some way the oversupply of philanthropists of this city, consumed with a desire to establish dispensaries, could have their attention diverted to the South, what a double blessing it would be! Or even if a few of our institutions now depending upon the "better classes" for material would consent to transfer the seat of their operations, what a relief to the army of willing, waiting, weary men who have been drawn into the metropolis by the false idea that private practice could be here pursued excepting among the very wealthy!

RECENT HAPPENINGS BEARING UPON THE LEPROSY QUESTION.

During the past fortnight there has appeared an unusual amount of leprosy literature in the public prints of this city. It is announced by cable that Dr. Besnier has returned to Paris from the leprosy congress in Berlin, and again startled his compatriots with a report that there are at least one hundred lepers abroad in the French capital. This, of course, has nothing very startling about it, since the same announcement was made over a year ago. New Yorkers seem to be developing a taste somewhat similar to that of the Parisians for shocking and being shocked. A year ago the health board of this city tried the effect upon the public of allowing its small colony of lepers to escape from North Brothers Island into the city. The shock produced was not marked, but seems to have been sufficient to encourage the board to perpetrate the farce a second time. We expressed our opinion of the whole procedure at the time, as well as of the board's attempt to secure the County Medical Society's backing for its act. Humanity would seem to demand that this class of patients be treated with more consideration and not run down like beasts, to be confined until the time comes around to turn them loose for another grand leper hunt.

If the health board has no jurisdiction over the leper, why does it not leave him alone?

In the Sunday edition of one of our most prominent daily journals, Dr. Fox adds to the health board's attempted shock by giving, in a half-page article, a detailed account of New York's lepers. The number at large is put down at twenty-five. He says that the disease is not contagious, and dilates upon the attractiveness of our climate and hygienic surroundings, under whose influence, combined with certain drug treatment, foreign lepers improve and even get well. The Skin and Cancer Hospital, he says, receives and keeps lepers for treatment. The writer invites attention to moral treatment of the patient as a therapeutic agent which is commonly overlooked. An appeal is made for the establishment by some wealthy individual of a special hospital for the study and care of leprosy cases.

In a reply to Dr. Fox's article, published in the same paper, Dr. Ashmead maintains the proven contagiousness of the disease, and quotes the conclusions of the Leprosy Congress, whose sessions have just closed in Berlin, in support of this view. The bacillus, he says, exists only in man, and treatment so far is merely palliative and not curative. Hansen's recently expressed opinion is cited, to the effect that if measures of isolation were universally adopted leprosy would be quickly eradicated. He asks Dr. Fox how leprosy can be regarded as a disease of insalubrious surroundings and filth if, as the latter has just claimed, it exists in this city in subjects close to the four hundred.

The most recent report of an epidemic of leprosy comes from far-off Tiflis, where the disease is reported to be assuming alarming proportions.

However, the practical and, it seems to us, important point to be determined for this country is whether we are destined to become burdened by the scourge. Is it not possible to make and maintain this a leper-free country, or rather, was it not possible some years ago when the Medical Record pointed out the dangers and undesirableness of fostering leprosy? We believe that even to-day, despite the reported increase, proper measures, such as have already been advocated in these columns, would in time save us from this preventable and most assuredly unwelcome disease.

News of the Week.

An Editor's Misfortune.—Dr. George Wilson, of Oxford, the editor and owner of the *Medical Magazine*, has disappeared, leaving behind many liabilities and no assets. He started the *Medical Magazine*, a most readable publication by the way, about six years ago, on borrowed capital. The venture ruined him, for the magazine was not of the character to win a large circulation at once, and notes fell due before subscriptions came in.

Death of Dr. Charles H. Avery.—Dr. Charles H. Avery, a practising physician in this city for thirty years and the secretary of the Medical Society of the County of New York, died on Tuesday night at his home, No. 238 East Eighteenth Street. He was born in Perryville, Madison County, N. Y., sixty-three years ago. He was graduated from the Long Island College Hospital and commenced his practice in a small village in the oil region of Pennsylvania. From there he came to this city. A chronic disease from which he had suffered for many years was the cause of his death.

Permanganate of Potassium in Opium Poisoning.—Surgeon-Major J. D. Reckitt reports, in the *British Medical Journal* of October 9, 1897, a case of a man, twenty-five years old, who had drank two ounces of laudanum. Permanganate of potassium, in five-grain doses repeated several times, was administered, and the man made a good recovery. He was seen too late to permit of removal of the poison from the stomach, so that the entire amount taken was absorbed.

In Memory of Benjamin Ward Richardson.—A subscription list was opened some time ago to endow a bed in the London Temperance Hospital as a me-

morial of the late Sir B. W. Richardson, who was one of the attending physicians to the hospital. The amount desired is one thousand pounds, but as yet only about one hundred pounds has been raised. Sir Benjamin was an ardent worker in the cause of total abstinence, having been perhaps the most active member of the British Medical Temperance Association.

The Alvarenga Prize of the College of Physicians of Philadelphia.—The next award of the Alvarenga prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14, 1898, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published, and must be received by the secretary of the college on or before May 1, 1898. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. The Alvarenga prize for 1897 was awarded to Dr. Joseph Collins, of New York, for an essay entitled "Aphasia."

American Students in Germany.—Referring to the difficulties the German authorities have placed in the way of foreign medical students, the editor of the *Columbus Medical Journal* remarks: "We admire the position taken by our German brothers in attempting to annihilate the fad that has swept over this country like a tidal wave, to the effect that no medical student had completed his education without having attended some medical school in Berlin, Germany; and still worse, if he attended some foreign school, if it were but for two or three weeks, that he was far superior to his brother practitioner who had remained in the land of his nativity and studied hard in schools of equal facilities in America. We do not blame the Germans for drawing the line on these half-educated medical students and practitioners who rush into their schools from America, as it is certainly a nuisance, and detrimental to the advanced standing of the German schools and reflects no credit on the medical profession of the United States. We are a firm believer in utilizing the facilities offered for medical as well as other forms of education in America before we seek admission to foreign schools. It is a fad which deserves severe criticism, and we hope our ambassador will sustain the action of the German government in this direction."

The Physical Condition of Applicants for Enlistment in the Army.—According to the recently published report of Surgeon-General Sternberg, of the United States army, the total number of men examined for enlistment during the calendar year was 14,659, of whom 8,654, or 590.35 per 1,000, were accepted; 5,448, or 371.65 per 1,000, were rejected on primary examination; and 557, or 38 per 1,000, subsequently declined enlistment. The ratio of accepted men per 1,000 of those examined was considerably larger than in previous years. This must be regarded, says General Sternberg, as meaning that better men physically are coming up as candidates for examination for enlistment. The rejections among the colored men were relatively somewhat more numerous than among the white candidates for enlistment—379, compared with 371.04 per 1,000 respectively. Although the foreign-born recruit has the advantage over the native white in weight and chest measurement, the latter is taller by one-half inch.

English Medicines in Germany.—At the recent meeting of the German Apotheker-Verein at Strasburg, Dr. Tschaschel, of Wulsdruff, brought before his fellow-members the question of the importation of foreign medicines. He specially referred to the manufactures of an English firm, which had recently distributed among medical men a pamphlet in which the properties and uses of the firm's preparations were described. He moved that the executive of the Verein should take steps to prevent the introduction of these articles into pharmacies, and explain the state of the case to medical men. He said that he had bought a bottle containing twenty-five morphine tablets, which professed to contain one centigram of morphine hydrochloride in each. The tablets weighed five centigrams, and therefore it was clear they contained some other substance besides the alkaloid, so that the pharmacist could not take any responsibility for them. A long discussion followed, and in the course of the discussion it was mentioned that the Frankfort pharmacists put a red wrapper on the boxes containing the tablets, on which was printed a statement that they were not responsible for the contents. A pharmacist said that in his town they had informed the physicians that they made such preparations themselves, and would dispense the ready-made one only if they were expressly ordered. A druggist of Hamburg said the medical society of that city had issued a circular to the physicians there, pointing out that if they prescribed packed medicines they took a special risk, for the apothecary who dispensed them could not tell what such medicines contained.

Typhoid Fever in Ireland.—A serious outbreak of typhoid fever is reported to have occurred at a suburb of Belfast, and it is feared the disease will become epidemic in the city.

A Question of Sanatorium Rights.—A case involving the right of the proprietor of a mineral spring to empty its waters into a stream flowing across the land of another, after the water has been used for bathing-purposes, has recently been decided by the supreme court of Indiana. The defendants were the proprietors of a medicinal spring and had established a sanatorium. After being used for bathing-purposes the water was allowed to flow into a stream which crossed land not belonging to the owners of the mineral spring. One of the adjoining landowners sued the sanatorium managers, asking that they be restrained from permitting to flow into the stream any water which had been used in bathing persons afflicted with syphilitic or other disorders. The court granted the injunction, but on appeal the supreme court set it aside and

directed judgment for the defendants, on the strength of the evidence offered that, although the water had an unclean and repulsive appearance, it was not poisonous or injurious to live stock or human beings.

Football Barbarism.—At a game of football between the University of Georgia and the University of Virginia on October 30th, one player was killed and another seriously injured. The authorities at the Georgia State University have not abolished the game, and a bill prohibiting football in the State, which failed to pass the last session of the legislature, will be reintroduced this year, and will doubtless pass this time by reason of the sentiment aroused by these casualties.

Yellow Fever.—The beginning of the end of the yellow-fever visitation in the South is at last in sight. There has been more or less cold weather throughout the affected region, and in many parts of Louisiana sharp frosts are reported. Even when the appearance of frosty weather is delayed, the history of previous epidemics shows that the fever decreases with the general lowering of temperature always obtaining at this time.

A Colored Woman Physician was among the applicants for a license to practise medicine at Atlanta, Ga., recently. She is a graduate of the Woman's Medical College in Philadelphia.

The Pray Medical Prize Essay.—The late Dr. Thomas J. W. Pray left to the New Hampshire Medical Society a sum of money making possible the offering by the society of a prize of $100 for the best original essay upon some medical topic, written by a member of the society. Essays must be in the hands of the trustees on or before April 1, 1899. Each essay must bear some signature, and be accompanied by an envelope marked by the same signature and containing the name of the writer. This envelope is not to be opened unless the essay gains the prize. The name of the successful writer will be announced at the annual meeting and the prize will then be awarded; and if the trustees so direct the paper shall be read before the society and published in the annual report. The essays are to be legibly written or typewritten, and not to be less than four thousand words and not more than ten thousand words in length. If no paper is presented which the trustees deem worthy of the prize, no award will be made.

Obituary Notes.—Dr. George F. Matter died at Shenandoah, Pa., on October 22d, of cerebro-spinal meningitis, at the age of fifty-seven years. He served as a hospital steward during the war of the rebellion with the two hundred and tenth regiment, Pennsylvania volunteers, and he was graduated from Jefferson Medical College in 1866.—Dr. Frank L. Sallade died at Womelsdorf, Pa., on October 24th, in consequence of a self-administered overdose of morphine and atropine taken unintentionally. He was fifty-three years old and a graduate of Jefferson Medical College. In addition to the care of a large practice, he was besides an accomplished artist.—Dr. A. L. Hummel, of Hummelstown, Pa., died at Denver, Col., October 26th, at the age of forty years. He was a graduate of the University of Maryland, and for a number of years was connected in different capacities with various medical journals.—Dr. Stephen Parsons died at Chester, Pa., on October 27th, at the age of eighty years. He was graduated from the Baltimore College of Dental Surgery in 1846, and from the Philadelphia College of Medicine in 1849.—Dr. Clarence G. Abbott, of Woodbury, N. J., died at Easton, Pa., on October 27th, at the age of thirty-eight years, after a long illness.—Dr. William Henry Corse died at Philadelphia, on October 28th, at the age of seventy-seven years. He was a graduate of the Philadelphia College of Pharmacy and also of the medical department of the University of Pennsylvania. Until eight years ago he was engaged in the practice of his profession at Wilmington, Del.—Dr. Alexander Milton Ross, of Montreal, well known as a naturalist of high order, died in Detroit on October 28th. He was born in Belleville, Ontario, in 1832. When a lad he came to New York and worked as a compositor on a daily paper, and while still at this work studied medicine under Valentine Mott, and received his degree in 1855. He was a surgeon with Walker's filibusters in Nicaragua, in the Union army during the civil war, and in the Mexican army under Juarez. After his return to Canada he became a member of the College of Physicians and Surgeons of Quebec and Ontario, and was one of the founders of the society for the diffusion of physiological knowledge in 1881. He then began to collect and classify the fauna and flora of that country, a work that had never before been attempted by a native. He collected and classified hundreds of species of birds, eggs, mammals, reptiles, and fresh-water fish, thirty-four hundred species of insects, and two thousand species of Canadian flora. Among his published works were: "Birds of Canada" (1872); "Butterflies and Moths of Canada" (1873); "Flora of Canada" (1873); "Forest Trees of Canada" (1874); "Ferns and Wild Flowers of Canada" (1877); "Mammals, Reptiles, and Fresh-Water Fishes of Canada" (1878).—Mr. Hermon M. Atwood, vice-president of the New York College of Pharmacy, died at his home in this city on October 29th. Mr. Atwood was born in Hartford fifty-eight years ago. He came to this city in 1858, and was one of the oldest druggists in the city at the time of his death. In 1870 he became connected with the New York College of Pharmacy, and in 1882 he was elected a member of the board of trustees.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending October 30, 1897. October 27th.—Medical Director W. K. Van Reypen detached as member of the board of inspection and survey and made chief of the bureau of medicine and surgery. October 28th.—Assistant Surgeon T. W. Richards detached from the *Maine*, ordered home to Washington, and granted two months' leave.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 25, 1897.

LANDON CARTER GRAY, M.D., PRESIDENT.

Report of the Treasurer.—DR. JOHN S. WARREN read his report. The disbursements had been $6,509.43, and the balance in the treasury was $821.39.

Report of Committee on Hygiene.—DR. W. H. KATZENBACH presented in this report an account of what had been done regarding the action of the board of health requiring notification of cases of tuberculosis. The details had been presented to the society last March.

Report of the Counsel.—DR. SENECA D. POWELL, in calling attention to this report, said that some idea of the work done by the legal counsel of the society might be gained from the statement that since the new law had been in operation one hundred and twenty-four arrests had been made for illegal practice of medicine, and seventy-six convictions had been secured. The aggregate fines imposed amounted to $5,115.

Report of Committee on Ethics.—DR. ARTHUR M. JACOBUS, after presenting a summary of the work done by this committee during the year, suggested that, in view of the fact that the rules of ethics of this society did not harmonize with those of the State society, and the rules concerning enforcement of discipline were not clear, this matter should be referred to the incoming comitia minora, and that power be given the comitia minora to enforce minor degrees of discipline without publicity and without appeal to the society.

DR. N. E. BRILL moved that the report be referred to the incoming comitia minora for action. Carried.

Committee on Prize Essay.—DR. WILLIAM STEVENS stated that the committee had received and carefully examined three essays. The committee recommended that the prize be awarded to Dr. Heinrich Stern, the author of the essay entitled "A Contribution to the Pathogenesis and Etiology of Diabetes Mellitus."

Amendments to the Bylaws.—In order to prevent unusual and unwarranted inroads on the treasury, the bylaws were so amended as to require the comitia minora to pass upon proposed appropriations and report to the society.

Committee on Legislation.—After a prolonged and somewhat heated discussion as to whether medical legislation in Albany could be best attended to by the board of censors, as heretofore, or by the proposed committee on legislation, the bylaws were amended so as to make the latter a standing committee, working under the direction of the comitia minora.

The Case against Dr. Van Fleet Non-Suited.—DR. D. B. ST. JOHN ROOSA announced that the president of the society and some other members of the profession had attended the trial in the United States court. It would be remembered that the society had voted to sustain Dr. Van Fleet. After hearing the plaintiff's testimony and the argument made by the society's counsel, the judge refused to allow the case to go to the jury; in other words, the court had practically decided that the society's meeting-place was a place of privilege, and that if reporters came there it was at their own peril.

Vote of Thanks to Dr. Van Fleet.—On motion of DR. ROOSA, the society tendered to Dr. Van Fleet a vote of thanks for his courageous defence of its rights at great trial and inconvenience to himself.

Resolution of Sympathy for Dr. Avery.—DR. E. H. GRANDIN offered the following resolution, which was unanimously adopted:

"*Resolved*, That the Medical Society of the County of New York sympathizes deeply with Dr. Avery in his illness, and expresses the hope that before long he will again be able to preside as secretary with his accustomed fidelity over the meetings of this society."

Election of Officers.—*President*, Dr. Arthur M. Jacobus; *First-Vice-President*, Dr. Nathan E. Brill; *Second Vice-President*, Dr. B. Farquhar Curtis; *Secretary*, Dr. Charles H. Avery; *Assistant Secretary*, Dr. William E. Bullard; *Treasurer*, Dr. John S. Warren; *Censors*, Drs. Landon Carter Gray, Walter Lester Carr, Herman L. Collyer, Floyd M. Crandall, and Frank H. Daniels.

A Contribution to the Surgery of Empyema, with the History of an Illustrative Case.—DR. CHARLES E. LOCKWOOD read a paper on this subject. After referring to the histology of the pleural sac and to the different varieties of pleurisy, he said that it was now believed that every empyema was due to microbic invasion of the pleural cavity. Statistics seemed to show that fifty per cent. of all cases were caused by streptococci, twenty-five per cent. by pneumococci, and the remaining twenty-five per cent. by several forms, of which tuberculosis was relatively the most common. In children the pneumococcus caused from sixty to seventy-five per cent. of all cases, the remainder being mostly the result of infection with streptococci or staphylococci. In all the different varieties of purulent pleurisy the treatment consisted of the immediate evacuation of the pus. There were four methods of accomplishing this, viz.: (1) Aspiration, (2) simple incision, (3) thoracotomy with resection, and (4) siphon drainage. Dr. L. E. Holt had collected one hundred and twenty-one cases in which aspiration had been done. Twenty-three of the patients were cured, six died, and ninety-two came to further operation. This gave twenty per cent. of cures; hence this operation was applicable in certain cases, and was worthy of trial in the mild cases and in those in which delay was not dangerous. It should not be done more than once. In children it had been found relatively more successful, probably because the empyemas of early life were usually produced by the short-lived and comparatively non-virulent pneumococcus. In some cases of tuberculous empyema which were latent, aspiration would seem to be most conservative. One observer had reported ten successful cases in adults suffering from pneumococcus empyema. Simple incision would seem to be especially applicable when general anæsthesia was not admissible and in the case of children. Morrison had given a series of thirty-four cases in which this operation had been done with only two deaths and an average duration of treatment of thirty-two days. Local anæsthesia by one-per-cent. solution of cocaine could be used. Thoracotomy with resection, in all cases not included in the cases heretofore mentioned, had seemed to give the most favorable results. In one hundred and seven cases in which incision had been done, there were sixty complete cures, or fifty per cent., and twelve fistulæ; while seventy-nine cases of resection gave fifty-five complete cures, or seventy per cent., and six fistulæ. The most important point was to secure thorough drainage, and if possible to avoid irrigation, which seemed to be dangerous and liable to prolong suppuration. From 1876 to 1880 all empyemas treated at one of the German clinics had been irrigated daily for an average period of one hundred and one days, with thirty per cent. of complete cures. From 1880 to 1885 only one irrigation was given, and the average duration was eighty-four days, and there were seventy per cent. of cures. From 1885 to 1890 irriga-

tion had been discarded entirely except in putrid cases, and the duration was fifty-two days, and there were ninety-six per cent. of cures. Siphon drainage consisted in tapping the chest with a large trocar, and after drawing off most of the pus inserting a soft catheter with a rubber tube attached, the distal end of this tube dipping into an antiseptic fluid contained in a bottle. The method was chiefly applicable to the chronic tuberculous empyemas and perhaps to the pneumococcus empyemas of adults.

A Septic Fever Controlled Only by Antiseptic Irrigation.—Dr. Lockwood then reported the following case: C. B——, sixteen years of age, a student, had lost three brothers, one sister, and one maternal uncle from pulmonary tuberculosis. His own health had previously been good. On December 10, 1896, he had a chill, and then the temperature rose to 104.8° F., the pulse to 108, and the respirations to 28. Examination showed an acute pneumonia of the lower lobe of the right lung and friction sounds indicating involvement of the pleura. For six days the morning temperature was 102° F., and the afternoon temperature 103° F. On the tenth day it was normal at 3 A.M., but had reached 100° F. at 3 P.M. For the next few days the temperature was normal in the morning and slightly elevated in the afternoon. Physical examination at this time showed pleurisy with effusion. On the seventeenth day the morning temperature was 99° F., and the evening temperature 103° F., and the patient suffered considerably from difficult breathing and pain in the right side. On the following day, December 28th, the speaker had seen him for the first time, and had aspirated the chest between the fourth and fifth ribs on the right side, drawing off twenty ounces of laudable pus. The next day the temperature was normal at 9 A.M., and 101° F. at 6 P.M. Examination of the sputum by Dr. Harlow Books showed considerable numbers of the diplococci of pneumonia, but no tubercle bacilli. On January 3d the boy was again aspirated between the fifth and sixth ribs, and twenty ounces of pus were removed. On January 5th an incision was made by Dr. W. T. Bull on the right side in the axillary line, over the eighth and ninth ribs, and portions of these ribs, one and one-half inches long, were removed. When the pleural cavity was opened a large quantity of fibrin and pus escaped. The cavity was irrigated with sterilized water and two large rubber tubes were inserted and fastened. To guard against danger from breakage, silk was passed through from end to end. The next day the morning temperature was 98.4° F., and in the evening it was 99.8° F. The dressings were changed three times in twenty-four hours. On January 16th the tubes were removed and the wound was irrigated, for the first time since the operation, with sterilized decinormal salt solution, and the tubes were cleaned and reinserted. For about one week the irrigations with sterilized water were done once a day, and it was then noted that the evening temperature seemed to have been higher since these irrigations had been used. However, they were continued for about another week. The patient now had night sweats, an anæmic murmur over the base of the heart, and slight œdema of the lower extremities. Dr. Janeway then saw the case. He expressed the opinion that the fever was septic, and recommended irrigation of the chest cavity with one drachm of carbolic acid to sixteen ounces of water, care being taken to measure the quantity introduced and removed, so as to make it certain that none of the solution was allowed to remain behind. The temperature was 103° F. at that time. On the following day, February 4th, the temperature remained normal all day and the irrigation was repeated. It should be noted that the septic fever prevailed about one month, and that it did not abate until the use of the weak carbolized solution. By February 18th the patient was able to take a short ride, and on April 26th the dressings were discontinued. On May 15th careful measurements of the chest were taken, and it was found that the difference between the two sides on inspiration was five-eighths of an inch, and on expiration one-fourth of an inch—a good showing considering the severity of the case. Great care was taken throughout the tedious convalescence to secure the highest possible nutrition. That there was a perforation in the lung was shown by the fact that the patient could breathe through the opening in the chest when the nostrils and mouth were closed, and it was probable that infection occurred through the introduction of micro-organisms in this way from the outside air.

Do Not Neglect Exploratory Puncture.—Dr. Beverley Robinson said that he had had under his care at St. Luke's Hospital last spring a little child who had been operated upon for pyothorax. The child was here this evening. He came in from the Orphan Asylum with the history of a pneumonia preceding his admission by some weeks. From the appearance of the child and from the physical examination it was supposed that the boy was possibly suffering from some malignant disease of the chest. Puncture of the chest was made, and purulent fluid withdrawn. A day or two later the rib was resected. After about two months he left the hospital cured, and was now in good condition.

With regard to the treatment of empyema, the speaker said that his individual opinion was that it was a mistake to allow ourselves to believe that mere puncture of the chest wall and withdrawal of the fluid one or more times was the best treatment, as he had found that it was not usually curative. Cases so treated usually required subsequent operation, preferably by resection of one or more ribs. The relative increase in surgical shock from resection of a rib, as compared with simple incision, he believed to be slight and unimportant. Simple aspiration was tedious and inefficient, and noncurative in a large number of cases; moreover, it did not, as a rule, allow of such efficient drainage as when the rib was resected. It was a mistake to attempt to operate on children under local anæsthesia, if for no other reason than the bad mental impression created. The only real risk attendant upon the operation of opening the chest and resecting a rib was that associated with the anæsthetic. He did not think that in the diagnosis of empyema we had any right to rely upon the general symptoms; unless we resorted to exploratory puncture we would almost certainly make grievous mistakes. It was a common but very erroneous belief that pleurisy was apt to change from the serous to the purulent form. Acute broncho-pneumonia in childhood was the most frequent cause of empyema in children, and, whenever there was any reasonable doubt during the course of the disease or following it, resort should be had to puncture to establish the diagnosis. There should be no danger from puncturing the lung with an aseptic needle. He had never seen any harm from such punctures when made with proper precautions. It was very difficult to recognize an empyema in connection with a pneumonia during the acute process; it was not so difficult after the period of crisis. He believed that it was bad practice to-day to irrigate the pleural cavity after an operation for empyema, unless we were compelled to do so by a fetid discharge, with or without rise of temperature, or by the presence of clots in the pleural cavity. Care should be taken, if a poisonous antiseptic fluid was used, that it should not be allowed to remain in the cavity. Personally he would prefer to use some non-poisonous antiseptic, such as boric acid or Labarraque's solution. Free drainage was, of course, all-important, and as it was difficult if not impossible in many children to secure this by simple incision, the advantage of resection of a rib was obvious. In an adult whose

pleural cavity had contained fluid for a considerable time it was difficult to see how the chest wall could retract sufficiently to allow healing of the abscess cavity unless a rib was resected.

Treat Pyothorax Like Any Other Abscess.—Dr. John B. Walker said that it seemed to him that the treatment of empyema should be the same as the surgical treatment of an abscess in any other locality. As an ordinary abscess was not treated by aspiration, it was not advisable to aspirate an empyema. The simple incision had the disadvantage of making it quite difficult to keep the wound sufficiently open to allow free drainage, and hence he favored resection of the rib. The tubes used should be as large as possible. In the case reported in the paper the tubes were about one-half inch in diameter, and the dressings were changed as often as they became moist. The effect of the weak carbolized solution upon the suppurative process had been exceedingly satisfactory.

Better do Too Much than Too Little.—Dr. Harry R. Purdy said that a rather extensive experience among children had taught him that empyema was not an uncommon disease in early life, and also that there was no other disease that was so commonly overlooked. If after scarlatina, diphtheria, measles, and pertussis a careful physical examination was made, these mistakes would not be so frequent. The most important physical signs were entire absence of vocal fremitus, immobility of the affected side, and the result of light and skilful percussion. He could not agree with the reader of the paper in calling any case of empyema "mild." In his opinion delay was always dangerous, and common sense would seem to indicate that the pus should be promptly evacuated by the resection of one or more ribs. Why waste time on the minor operations, when seventy-five or eighty per cent. of cures could be obtained by this method? The dread of giving an anæsthetic was not a proper excuse for delaying such an operation. He had seen children so weak that they had to be carried around on a pillow stand the anæsthetic perfectly well. He recalled one case in which the mother would not consent to an operation, and the child got well owing to the fortunate circumstance that the pus discharged through a bronchus. The operation of simple incision was not a good one for children, because of the narrowness of the intercostal spaces. The operation of resection should not be confined simply to so-called cases of empyema, for at times the so-called serous effusions did certainly become purulent. In cases of protracted pleurisy or of frequent reaccumulation of the fluid, he would, with Koplik, advise resection. There was more likelihood of failure in these cases from doing too little than from doing too much. In illustration, he cited the case of a baby who had been brought to him one year ago in a feeble condition. It had apparently suffered from empyema for many weeks, and was also enfeebled from pertussis. About two-thirds of a pint of pus was removed by operation, and with very marked improvement in the general condition. The discharge was continuous, but the mother would not consent to another operation. He had therefore dressed the child faithfully for a year, and then the little one had been admitted to St. Mary's Hospital. Here she had been operated upon again on July 27, 1897, an incision being made along the old sinus. The fourth, fifth, and sixth ribs, with portions of the seventh, were removed, together with the periosteum and parietal pleura. The latter was enormously thickened. The wound was packed, and a week later the child was sent to the country. Here chicken-pox developed. A sinus was left, and a week ago a further resection was done. The present condition of the child was quite good, considering the history of the case.

Remove Coagula through a Pleural Speculum.—Dr. Carl Beck said that several years ago he had presented to this society a paper on this subject. Fifteen years ago he had recommended resection of the rib for all cases of empyema without exception, and had been bitterly opposed by distinguished members of the profession. It was therefore with great satisfaction that he observed this evening the harmony of opinion regarding the advisability of treating these cases by resection, incision, and drainage. There was no reason why such cases should not be treated on the same principles as governed the modern surgeon in the treatment of any abscess. In the treatment of an abscess the surgeon would not only secure a large opening and free drainage, but he would scrape the lining membrane and remove the necrotic tissue and the attached microbes. He would not think of using irrigation, for after such careful treatment it would not be necessary. Irrigation of the necrotic membrane meant irrigating dirt; it was better to remove the dirt. In cases of empyema there were often very large solid masses—sometimes as large as a man's fist—and he could not understand how such cases could be successfully treated by aspiration or even by simple incision. It was evident that these masses under such circumstances must be left behind to dissolve and escape slowly in the discharge. It seemed to him that in the case reported in the paper there must have been necrotic membrane which had been gradually washed out with the irrigations. He was not inclined to think that it was the carbolic acid that should be credited with the improvement, but rather the mechanical effect of the irrigation. If more attention had been given to the removal of necrotic tissue at the beginning, the history of the case would have probably been different. He advised the use of a "pleural speculum," with the aid of which it was easy to see the fibrinous clots and remove them. Only at this time was it necessary to irrigate the cavity. In recent years he had preferred to pack the cavity with iodoform gauze, packing it tightly for two or three days, and after this using a loose packing. Since the adoption of this treatment he had but rarely seen death occur in an uncomplicated case. He preferred to call these cases "pyothorax," because empyema referred to collections of pus, without designating the locality.

Remove the Cause by the Use of Strong Carbolic Acid.—Dr. Seneca D. Powell said that a pus pocket was a pus pocket, no matter where it was found or whether in a child or in an adult. The two important points in the treatment were (1) the establishment of perfect drainage, and (2) the removal of the cause of the infection. In order to remove the cause, one should use a germicide which could be employed safely in a strength that would be efficient. He claimed that the only germicide fulfilling these conditions was carbolic acid. Pure carbolic acid could be applied to one's hands for a moment, and then the action of the acid could be limited by washing in alcohol. He would advise swabbing out the cavity with pure carbolic acid after having curetted away the necrotic tissue, and then packing the cavity with gauze. If good drainage could be obtained by an incision, then all was accomplished that was necessary. Except in long-standing cases, he thought it was but rarely necessary to resort to any extensive resection.

Dr. Lockwood, in closing the discussion, said that he was very glad that the discussion had emphasized the fact that the best treatment was the recognized surgical treatment for abscess. It was also well to remember what Dr. Robinson had said about the great importance of exploratory puncture in establishing a positive diagnosis.

The Clinical Importance of Impacted Pelvic Tumors.—Dr. Henry C. Coe read only a portion of this

paper, because of the lateness of the hour. He said that the subject was one which really concerned the general practitioner. Pelvic neoplasms often remained unrecognized, and the pressure symptoms to which they gave rise were often misinterpreted. A small tumor, from the size of an English walnut to that of a baseball, might cause no special symptoms until it became impacted in Douglas' pouch or surrounded by inflammatory exudate. In the latter case the symptoms were often quite marked, and the patient's general health would probably suffer greatly. The symptoms produced by impacted pelvic tumors were often referred to the pelvic and abdominal viscera, and the physician was thereby misled. The amount of pain was frequently entirely out of proportion to the size of the growth, and distant organs might be affected—as, for instance, through pressure on the ureters. When such tumors complicated pregnancy, they deserved the serious attention of every practitioner. The importance of intrapelvic tumors varied according to their anatomical character, their mode of development, and their locality. Thus a rapidly growing cystoma would possess more significance than a small subperitoneal fibroid. Again, a tumor impacted in Douglas' pouch possessed more importance, from a clinical standpoint, than an intraligamentous growth of the same size and variety. For practical purposes, as the tumors impacted in Douglas' pouch were the most common, they alone would be considered.

Reflex Pressure Symptoms Liable to Mislead.—The most obvious effects of such tumors were those resulting from pressure. The uterus, from its mobility and anatomical relation to the neoplasm, was apt to be first affected. Procidentia, occurring in a young woman with a good pelvic floor, should be regarded as probably an indication of pressure from above. The rectum would always be more or less encroached upon by growths in the cul-de-sac, and the bladder naturally shared in the pressure effects. Still more serious were the results of direct pressure of fibroids in the lower uterine segment. The results of pressure on the intrapelvic portion of the ureter were well known. The general venous congestion of the pelvic organs in connection with impacted tumors was frequently noted on the operating-table. Varicose veins of the labia and hemorrhoids presented external evidence of obstruction to the circulation. The distinction between an impacted and an adherent tumor was important. When the neoplasm was attached to the uterus and rectum, the pressure effects were exaggerated. A small tumor, which previously gave rise to no symptoms whatever, might, under the influence of pregnancy, not only increase in size, but contract adhesions which would permanently imprison it in Douglas' pouch. A case was cited in which a cystic tumor complicated pregnancy. He had been able to push it up out of the way of the descending head and to deliver easily, but in a second pregnancy the tumor was found to be impacted, and it became necessary to perform abdominal section. Colicky pains and pains in the appendical region were common in connection with extensive intestinal adhesions. In two cases of sudden dislocation of subperitoneal fibroids, seen in consultation, the symptoms exactly simulated those of a ruptured ectopic sac. Obstruction to the passage of fæcal matter, tenesmus after defecation, and a sensation as if the lower bowel had not been completely emptied were all suggestive of pressure on the lower bowel. More or less complete obstruction of the lumen might be indicated by the small size of the fæcal masses. One might be frequently led to suspect the presence of an intrapelvic growth in young girls by persistent hemorrhoids, which could not be explained in any other way. The bladder symptoms were sometimes the only evidence of a pelvic growth encroaching upon the pelvic organs. In the absence of satisfactory evidence of disease of the genito-urinary tract, the possibility of pressure upon or dislocation of the bladder should be borne in mind. Rectal palpation should never be omittted; in young girls it alone was permissible, and fortunately the information thus obtained was often conclusive. If the examination were not at first entirely satisfactory, it should be repeated under an anæsthetic. The present comfort and the future safety of the patient had both to be considered. Constant and severe pain, steadily increasing in spite of local treatment, was a sufficient indication for operative interference. Marked pressure symptoms, in connection with the steady growth of a tumor, were an ample excuse for operation. Only an imperfect idea of the extent of pelvic adhesions could be gained through a vaginal incision, and the operation could be done more thoroughly and intelligently through a free abdominal incision.

Impacted Tumors Complicating Pregnancy.—When impacted tumors complicated pregnancy they were especially dangerous, because they gave rise to no symptoms directing the attention of the patient or of her physician to the condition in the early months. This should emphasize the importance of a routine examination during pregnancy, even though the physician had previously attended the patient in confinement. Before the seventh month, if repeated and careful attempts to dislodge the mass failed, the patient being in the knee-chest position and if necessary under anæsthesia, the question of interference at once arose. Previous to the fourth month the induction of labor might be elected. After four and one-half months he would insist upon the choice of cœliotomy, even though the tumor was small and accessible through the vagina. Should premature delivery occur, no harm would result. He disliked the vaginal route for the removal of growths in pregnant women. The frequency with which dermoids became impacted in the cul-de-sac, and their liability to undergo changes, made it imperative that they should not be subjected too long to pressure by the uterus. Induction of labor offered a little more chance to the child, and exposed the mother to practically the same risk as at term. Cœliotomy must eventually be performed, because of complications resulting from mechanical injury to the tumor. The management of labor at term, when complicated by impacted tumors, was a purely mechanical problem. Sometimes the sac could be diminished in size by tapping or even by incision. In the presence of an impacted solid growth, one must be governed by its size and relations to the birth canal. The performance of cœliotomy did not necessarily imply Cæsarian section, as the tumor could be removed by abdominal section and the child delivered through the natural passages.

Place the Pregnant Woman under Medical Supervision.—Dr. Edward H. Grandin accepted the position taken by the reader of the paper. The first thought suggested to him by the paper was the necessity for examining a pregnant woman as early in pregnancy as possible. He believed that the medical profession had become convinced of the necessity of this, but it yet remained to educate the laity to the fact that the interests of both mother and child demanded that the pregnant woman should place herself under the care of her physician as soon as she was aware that she was pregnant. It was surprising how far a woman might be advanced in pregnancy before a tumor would become impacted; hence the great importance of its early recognition, that such a catastrophe might be averted. In his opinion it was as safe at the present time, even in the early months of pregnancy, to remove the tumor as to interfere with the progress of gestation. It was not traumatism that did

damage, but dirt. He did not think we were called upon to interrupt the progress of gestation in any case when a properly performed abdominal section would enable one to remove the growth. He would always prefer attacking such a tumor from above, except when he was satisfied that it was really a pus collection, in which case the vaginal route was the proper one. Through the abdominal opening the operator could best determine the relations of the tumor, the extent of the peritoneal adhesions, and also whether or not the appendix vermiformis was affected—a not uncommon complication. Later on in pregnancy, unless the symptoms were urgent, as the chances were in favor of a radical operation, it was better to postpone the operation, if possible, until the child was viable. The vaginal route should never be selected for such an operation, unless pus was present.

Does the Gravid Uterus Press upon the Ureters?—Dr. Freeland Barbour, of Edinburgh, being invited to participate in the discussion, said that he desired to emphasize the importance of the statements made regarding examination through the vagina and rectum in determining the position and fixation of these tumors. He related the two following cases:

The first case was one of a dermoid tumor impacted in the pelvis. It had given rise to no symptoms until the woman had become pregnant. At the time he had seen her, the symphysis and the tumor were only about two inches apart; the tumor was embedded in the cellular tissue and could not have been taken out without a very serious operation. The patient was unwilling to be exposed to such a risk, and therefore labor was induced at the seventh month, and, by turning, a living child was delivered. In the Edinburgh school, he said, they did not attach so much importance to the induction of premature labor as had been intimated in the remarks made this evening. This patient recovered perfectly, and had since been quite well.

The other case had impressed upon his mind the great seriousness of these tumors through implication of the ureters. He would like to know what theory those present entertained regarding the manner in which the ureter was affected. His own theory was that the tumor simply pushed the ureter aside in the same way that the pregnant uterus did, and that when pressure occurred it was due rather to inflammation. He knew, of course, that some had held that the pregnant uterus compressed the ureters at times, but some years ago he had made a number of dissections and had carefully traced the course of the ureters, and in this way had satisfied himself that the risk of the ureter being compressed between the bony walls of the pelvis and the gravid uterus was very small. In the case referred to there was also a hydronephrosis, and on tracing the ureter it was found that the ureter was completely embedded in and occluded by cicatricial tissue, which had developed in connection with the growth of the tumor.

More Tumors Imprisoned than Impacted.—Dr. A. Palmer Dudley said that the clinical importance of impacted pelvic tumors grew with our knowledge of pelvic disease, and the clinical importance of the same, with respect to the patient, depended upon our ability to explain that condition properly to her. He believed that more pelvic tumors were found imprisoned than impacted. It was sometimes very difficult to convince the patient that distant reflex pains had their origin in pelvic disease. One of the most important of such reflex affections was neuralgia about the eye. Any condition which interfered with the diaphragmatic action of the pelvic floor became just as dangerous to the patient as an impacted tumor. The retroflexed uterus might become an impacted tumor. Our object should be carefully to differentiate between the different growths, and in doing this we should take into consideration the age of the patient. In probably nine out of ten cases the abdominal route was the better one for both the patient and the operator.

Pressure on the Ureters Leads to Serious Disease.—Dr. George W. Jarman said that in a recent autopsy he had found distinct evidence that the tumor had produced sufficient pressure on the ureter to cause the death of the patient. If an impacted tumor involved one or the other side of the broad ligament, even though there were no bladder or rectal symptoms, operation was especially indicated. He was convinced that many deaths after operations for fibroids were due to latent kidney disease caused by pressure upon the ureter.

Danger from these Tumors even after Delivery.—Dr. Robert A. Murray said that about fifteen years ago there had been an important discussion regarding the effect of tumors on the pregnant condition. At that time the opinion seemed to be that these tumors should be left alone, and that as a rule they would be sufficiently lifted up out of the way to admit of delivery. But fifteen years had made a great difference in our opinions, and also in the mortality in these cases. While it was true that sometimes the tumor rapidly disappeared during the involution of the uterus after labor, it was equally true that the patient not infrequently became septic as a result of the injury caused by labor. In a Cæsarean section done at full term on a uterus containing many fibroid tumors, there was great danger of septic peritonitis. He would favor in these cases extirpation of the uterus. We should never hope against hope, believing that the tumor would be lifted out of the pelvis, delivery effected, and that then no further complication was likely to take place. This was a serious mistake.

Dr. Coe, in closing the discussion, said that he agreed with Dr. Barbour that in most cases of compression of the ureter the result was due to inflammatory action, yet he had seen one or two autopsies in which, so far as could be ascertained, hydronephrosis was due to direct pressure, particularly from intraligamentous growths.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 26, 1897.

John Slade Ely, M.D., President.

Lipoma of the Diaphragm.—Dr. Lewis A. Conner presented several specimens. The first was a fatty tumor which projected from the diaphragm into the left pleural cavity. It was found at an autopsy on an old woman who died of cerebral hemorrhage. The tumor was situated a little to the left of the cardiac apex and more posteriorly. It measured four by three centimetres, was sessile, and was covered with the diaphragmatic pleura. On the under side was to be seen what appeared to be a deficiency in the diaphragm which might possibly explain the origin of the tumor. There were no adhesions to the surrounding organs beneath the diaphragm, or evidence of attachment to the omentum. This was the first time that the speaker had met with a tumor in this situation.

Malignant Endocarditis.—The next two specimens were hearts exhibiting the lesions of endocarditis. The first one had been taken from a laborer, thirty years of age, who had been admitted to the Hudson Street Hospital on December 2d. He had had rheumatism years before, and had been told that there was some cardiac affection, but it had caused him no inconvenience. Shortly before death he had been sud-

denly attacked with irregular chills, fever, and sweating, and on admission had a temperature of 100.4° F. The heart dulness was increased, and at the apex were to be heard a diastolic thrill and murmur, and there were all the signs of an old mitral stenosis. The spleen was enlarged, and there were a few spots over the abdomen which resembled the eruption of typhoid fever; indeed, both the tongue and the general appearance of the patient suggested this disease. Examination of the blood showed no malarial organisms. A specimen of the blood was sent to the board of health, and was reported to have given the typhoid reaction with the serum test. A few days later a distinct double murmur developed over the base of the heart, in the aortic area, and the pulse became harder. A diagnosis was then made of endocarditis. He lived ten days longer, and during this time the murmur was changeable. During the last three or four days there were distinct pericardial friction sounds. With the exception of the chills the clinical picture was that of typhoid fever. At autopsy the pericardium was found to contain ten ounces of red fluid, and the parietal and visceral layers were injected and everywhere covered with a thin layer of fibrinous exudate, giving a granular appearance to the surface. The heart was moderately enlarged; its cavities were all dilated; the muscle was rather soft. The mitral orifice admitted only the tip of the little finger; the valve was much thickened and the chordæ tendineæ were shortened. At the base of the posterior cusp of the mitral valve was a soft, recent, reddish thrombus, measuring two centimetres at the base and one centimetre in thickness. On the anterior cusp of the anterior valve, midway between the mitral and aortic valves, was a large whitish vegetation, measuring two centimetres at the base and 1.5 cm. in thickness. The cusp was considerably thickened, and the sinus of Valsalva was greatly enlarged by what appeared to be an aneurismal dilatation. This formed a prominence on the wall of the left auricle, corresponding to the seat of the first-mentioned thrombus. The other valves were normal. Both kidneys contained a number of small yellow infarcts. The aneurismal pouching of the sinus of Valsalva was evidently the cause of the thrombus, although there was no perforation.

The next specimen showed a malignant endocarditis affecting the pulmonary valves. The specimen had been removed from a woman, thirty-eight years of age, who had been admitted to the New York Hospital after an illness of a few days. She had had several chills and at the time of entering the hospital presented the clinical picture of a lobar pneumonia. This was the diagnosis made in the hospital. A loud systolic murmur was heard over the base of the heart. The autopsy showed the spleen to be enlarged to three times its normal size. The kidneys were normal except for some cloudy swelling. There were areas of recent exudation over both pleural surfaces. The left lung contained two areas of hemorrhagic infarction in the lower lobe. In the centre of each small area of broken-down tissue in the right lung were several small but similar areas of infarction, and near some of these were found emboli in the branches of the pulmonary artery. In the lower part of the upper lobe there was quite an extensive area of consolidation, with an area of softening in the centre. The heart itself was about of normal size. The mitral, aortic, and tricuspid valves were apparently normal. There was a mass of fresh friable vegetation arising from the posterior and under surface of the pulmonary valve.

The speaker called attention to the great difference in the clinical picture in the two cases of endocarditis. Vegetations, he said, were very much more common on the left side of the heart than on the right. When the left side of the heart was involved, emboli were washed into the general circulation, instead of into the pulmonary circulation; hence the great difference in the clinical picture in the two classes of cases.

Aneurisms of the Aorta; Rupture. — The next specimen presented by Dr. Conner consisted of a remarkable series of aneurisms of the aorta. It had been taken from an old man, seventy-three years of age, who had been admitted to the Hudson Street Hospital on March 14, 1897, in a state of coma. The man had been found ill in the street, but had been able to walk to the police station. A few hours later he had been removed to the hospital in an ambulance. No complete physical examination was made before his death, which occurred in a few hours. At the autopsy the left pleural cavity was found completely filled with clotted and fluid blood. The pericardium and heart were displaced to the right beyond the median line. Occupying the normal position of the heart, and pushing forward the parietal pleura in that region, was a rounded tumor, the size of a large orange. The left lung was completely collapsed and its apex converted into fibrous tissue. The apex of the right lung showed some fibrous nodules and tuberculous deposits. The heart was extremely small; its valves were apparently competent. The aorta, from its beginning to its passage through the diaphragm, was enormously dilated and converted into a series of irregular pouches, the largest being ten centimetres in diameter. About twenty centimetres from the aortic valve, in the upper part of the descending aorta, was a transverse linear rupture, about three centimetres long. The sac contained for the most part fluid blood. The dilatation of the aorta continued down to within about six or seven centimetres of the bifurcation. The intima of the aorta everywhere was the seat of atheroma and calcareous deposits.

Dr. Warren Coleman said that he had seen several cases of malignant endocarditis occurring on the right side during the puerperium. He had never seen the pulmonary valve so affected.

The President said that he had seen a few cases in which the pulmonary valve had been affected. Naturally in these cases pulmonary emboli were also found.

Dr. Conner said that in the cases he had reported there had been no evidence of an outside infection; in other words, it was a secondary process. The streptococcus pyogenes was found in each of them.

The society then adjourned.

Fractures of the Skull.—In a consideration of the permanent or later results of these fractures Dr. William N. Bullard (*Boston Medical and Surgical Journal*, April 29th) draws the following conclusions: "1. Out of seventy persons with fractures of the skull, thirty-seven presented no symptoms when examined some time later. 2. Only seven persons presented serious symptoms, and in at least four of these it is doubtful whether the symptoms were due to the injury. 3. The most frequent consequences found were headache, deafness, dizziness, and inability to resist the action of alcohol on the brain. 4. Out of the fifteen cases in which operation (trephining, etc.) was performed, twelve had no symptoms; in another it was doubtful whether the symptoms present were due to the injury; in another the symptoms were slight (headache rare, tension over the wound while lying in bed); the other was deaf, but had no other trouble. We are justified, therefore, in concluding, so far as our statistics lead, that those cases in which trephining was performed have shown much better results, as far as the symptoms discussed are concerned, than those in which no operation was performed."

Clinical Department.

TENOTOMY IN CONVERGENT SQUINT.

By A. BETHUNE PATTERSON, M.D.,

ATLANTA, GA.

The guiding muscles of the eyeball are the internal and external recti, the superior and inferior recti, and the oblique, and are the muscles involved in strabismus. There are several methods of treating strabismus, which are based upon the theories entertained as to the cause, and which will not be taken into discussion here, as the principal object is to call attention to the too frequent and unscientific operation of cutting the internal rectus muscle in convergent squint.

The indications in cross-eye have always been to straighten the eye; modern research has led us a step farther, and established a second indication—that of re-establishing the function of observing with the deviating eye, for binocular vision becomes suspended soon after parallelism of the visual lines is lost; coincident with the deviation, double vision makes its appearance and is usually of short duration, for the squinting eye soon learns to suppress its image. The fusion of the two images when once suspended is by no means easily restored; it is a tedious and painstaking task to bring about a restoration of the physiological function, and should be of grave concern to the conscientious operator. It must not be understood that the straightening, or more properly the apparent straightening, has restored to the eye its former habit of seeing; but, on the other hand, when fusion takes place it is proof positive of the parallelism of the lines of vision.

I hold that the treatment can be regarded as successful only when these several conditions are realized, for the eye is useless and virtually blind so long as the image is allowed to remain suppressed; then it should be the principal object in the treatment or management of squint to restore to the eye its physiological usefulness. This becomes exceedingly difficult and in many cases impossible after cutting the internal rectus muscle, because after a complete severance of the internal rectus the eye turns a little up and remains in this position. This hyperphoria becomes a grave complication, and must be overcome before binocular vision is attained.

It might be said that considering the strabismus operation from a cosmetic standpoint only is an obsolete custom, yet there are a few old operators who continue the practice of twenty years ago. It is to be regretted that this branch of eye surgery has been neglected by many of our distinguished operators. It is true that the simple tenotomy is the quickest and easiest way of disposing of these cases, and, coupled with the fact of the improvement in the appearance of the subject that follows, it is satisfactory to those who are ignorant of the true condition.

In an article published in the *Southern Medical Record* six or seven years ago, I protested against the indiscriminate cutting of the internal rectus in convergent squint. The following I select from a number of cases illustrative of the evils of which this paper complains, of operating wholly from a cosmetic standpoint:

Miss P—— had her internal rectus muscles cut for convergent strabismus by a distinguished surgeon a short time after the squint appeared. The double vision had subsided only a few weeks. The operator was ignorant of the existing hypermetropia, or farsight, which was three and one-half diopters. When she came under my treatment there was still a slight convergence, with the usual turning up (eso-hyperphoria). I succeeded in re-establishing binocular vision by doing a graduated tenotomy and correcting the hypermetropia with glasses. I feel very confident, if her hypermetropia had been corrected at the time of the first operation, and accommodation had been kept quiet by the instillation of atropine for some time, that the cutting of the muscles would not have been necessary.

Very many cases of convergent strabismus in children are due to far-sight, and if taken in hand early can be cured by glasses which correct the refractive error; then again there are many others due to a weak external rectus, which can be cured by developing the weak muscle. A complete severance of the muscle should be made only after a due consideration of all the conditions incident to strabismus.

PAROXYSMAL TETANOID.

By N. GORDON PRICE, M.D.,

NEW YORK.

Under this heading I desire to mention a train of peculiar tetanic symptoms arising as the result of mental overexertion. This condition was brought to my notice several months ago by my friend, Dr. Rosentover, who has been for quite a time subject to these paroxysms, and I have had occasion to confirm the existence of this phenomenon and to become more familiar with its details through personal experience.

I bring this condition before my medical brethren, not because the condition *per se* is of much importance, but because I am in the hope that its recital may throw some new light upon the influence of prolonged cerebration upon the motor apparatus of the human economy, the motor centres primarily and the muscular and nervous system secondarily.

The only etiological factor I am familiar with is hypercerebration, brought about in numerous ways; as, for example, the result of close and constant application of the mind to reading material requiring deep thought and concentrated attention, or as the result of brooding over unhappy thoughts.

Apparently this factor disturbs the cerebral equilibrium, rendering the happy harmony of will and action discordant; it severs the normal relationship of the motor and volition centres, and permits for a time the motor apparatus to act independently, although the will power retains its normal vigor—the motor centres being in a state of revolt, as it were.

The attack is most prone to come on when the subject is in the supine recumbent position, and especially at night on retiring, provided cerebral activity is allowed to continue. Quite a remarkable fact is that if a person is once attacked, tetanoid may be brought on voluntarily merely by fulfilling the above condition, *i.e.*, deep thought after prolonged mental work on retiring.

The attack is usually ushered in by prodromal signs, whose proper significance only experience can teach one to interpret. These signs are as various as are those of the epileptic aura, though most frequently they are of the auditory type; hearing is acutely and painfully exaggerated, and peculiar hallucinatory noises are heard, such as the rushing of water down a fall. Sometimes the aura is of a sensory type, in the form of one of the paræsthesiæ, the sense of formication being most frequent. These premonitory symptoms last a few seconds, when the attack itself comes on. If these symptoms are correctly interpreted, the oncome of the attack may be prevented by moving any of the voluntary muscles.

In the attack itself we have a faithful representation of the tonic rigidity of a tetanic convulsion—the vol-

untary muscles contract spasmodically, trismus is present, the extremities are violently extended, and palpitation of the heart is a frequent accompaniment. Consciousness is maintained throughout the attack, opisthotonos is absent or slight, and the contractions are perfectly painless. The will power is normal; intellection is normal, as a rule, though in some attacks it is impaired; there is a dread of death present, and the person feels as though he were bound in chains, being unable to move any of his muscles.

One is taught by experience that if he succeed in exerting his will to such an extent as to enable him to move any of the voluntary muscles, as the vocal cords or even the levatores palpebrarum, he will cut short the attack and compel the motor centres and muscular system to reassume their natural subservience to the will. The seizure lasts a few minutes, though to the afflicted it seems so many ages; its withdrawal is a signal for a free general sweat and for a grateful relief from all the symptoms, mental and physical. If cerebral activity is still continued, as many as five or six attacks may be brought on, one following the other in rapid succession. The attacked, to eliminate further seizures, must drive away all thought, lie in the semiprone position, and imagine nothing, except that he is a log, incapable of thought.

The specific cause and precise nature of this phenomenon are, I must admit, entirely obscure. The attack will probably be explained as epileptiform, but this will be merely evasion, and resemble the answer of the philosopher, who, when asked, "What is mind?" answered, "No matter;" and when asked, "What is matter?" replied, "Never mind."

The elucidation of this peculiar puzzle I will leave to those who are more qualified than I am to probe into the depths of neurological phenomena.

139 Columbia Street.

FLOATING KIDNEY.

By SARAH E. POST, M.D.,

BROOKLYN, N. Y.

Recently a patient sent for me, complaining of abdominal pain, nausea, anxiety, and general distress. I found the woman in bed. Examination easily found the right kidney presenting, its upper border, I think, inclining to the abdominal wall. The patient is the mother of ten children. I have found the relative frequency of these cases somewhat determinable. My first case I came to in the dispensary of the Woman's College, as early as 1883 or 1884, my first year of practice. The complaint was in a young woman, who appeared at the clinic of general medicine. Difficult urination was the prominent symptom. The kidney was not made out, and the diagnosis depended upon the nausea and the general distress. Another case was met about five years later in the Demilt Dispensary, evening class, then devoted to general medicine. This woman did not show the displacement at the time. Another time I was called to her house and found her in bed, with the kidney easily recognizable. This woman was about thirty-five years of age, and had an unyielding retroflexion of the uterus. A truss was fitted to the kidney. A third case was met almost five years later in the same clinic, then given up to gynæcological and skin troubles. I mention the latter because the patients did not have to ask care for a gynæcological complaint, and the inference is not clear that this one came even suspecting such a trouble. In my last case my first thought was to anticipate miscarriage and to look for the enlarged uterus. Even with the third case in mind, however, I have no ground for thinking that the patients themselves ever make this mistake. The third case was in a woman, twenty-five years of age. She came in the height of the distress, with all the symptoms marked—flushed face, difficult urination, nausea, and pain, distress and anxiety predominating. The kidney could be found protruding. It could be returned and held by a compress and bandage.

In fifteen years' practice, including dispensary work, four of these cases have come to me, the intervals being nearly uniform, each being about five years. The first year brought a case as serious as those that came to me later. The use of a compress and bandage with a week in bed has been the usual treatment. I have not found the cases such as to suggest operation. The second patient has returned to me. One has such attacks only now and then. Another had had one such attack six years previously.

A METHOD FOR PREPARING STERILIZED CATGUT.

By S. H. CHAMPLIN, M.D.,

CHICAGO, ILL.

If a catgut ligature be chromicized and then boiled thirty-five minutes in water, it will resist absorption in the tissues from ten to twenty days, according to size. The following is the method I have adopted: A catgut ligature of any length desired is wound in a single layer around a No. 5 or No. 7 cork; it is then sunk in absolute ether for twenty-four or thirty-six hours. On removal from the ether the cork is placed in the open air until the ether in the catgut has entirely evaporated. The cork is then sunk in the following solution: Potassium bichromate, two parts; formalin (forty per cent.), four parts; water, ninety-four parts. At the end of four days the cork is taken from this solution and washed a few minutes in running water, and is then sunk in boiling water for thirty-five minutes. The catgut may then all be stored in one large sterilized jar—or, better, each ligature may be kept separately in a small, wide-mouthed bottle, the bottle and cork having been previously boiled.

Corks are used instead of glass spools, because a certain amount of shrinkage takes place in the gut, and if wound on glass the ligature becomes flattened into a ribbon-like strand and loses much of its toughness.

Catgut prepared in this way does not become brittle if boiled only once, and it may even be boiled a second time for ten minutes without detriment. If boiled only fifteen minutes the first time it may be boiled a second or a third time for fifteen minutes each time. The water should be at the boiling-point before the catgut is dropped into it.

A piece of No. 6 catgut prepared as above was passed through the abdominal wall of a patient on whom I performed abdominal section, and used together with others of silkworm gut as an approximation suture. On the tenth day the sutures were removed, and the catgut, like the others, had to be cut. It was found to be very pliable and about one-half its original size, and required considerable force to break it. The peritoneum, recti muscles, and fascia had been closed by continuous sutures of catgut from the same cork.

Later I buried three pieces of No. 6 gut under the skin of a dog. One piece, removed the seventh day, was bleached from a brown to an opaque white, but otherwise was very little changed; the second piece, removed on the twelfth day, was very much reduced in size, and after being dried it was broken with moderate force; the third piece was looked for on the twentieth day, but could not be found.

This catgut has been used in pelvic operations, herniotomy, and a great variety of subcutaneous operations, and no infection has taken place.

It seems to me that a No. 12 catgut prepared as above would make an ideal bone suture. I have prepared only sizes Nos. 4, 6, and 8; probably the larger sizes would have to remain in ether and the bichromate solution somewhat longer.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE ELECTION; MR. HORSLEY SUCCESSFUL—THE MAIDSTONE EPIDEMIC—TYPHOID IN A LONDON HOSPITAL—MEDICAL SOCIETY OF LONDON—CLINICAL SOCIETY—DR. ALEX. HILL—DR. BISHOP HICKS—MR. ERNEST HART—DEATHS OF DRS. BARRY, R. SMITH, J. LONG, AND WICKHAM.

London, October 15, 1897.

The election is over and Mr. Victor Horsley is our new direct representative in the General Medical Council. It is estimated that more than thirteen thousand votes were recorded and that Mr. Horsley's majority is nearly six hundred, but the exact figures cannot be given for another day or two. The result will, I believe, give general satisfaction.

The epidemic of typhoid at Maidstone is still extending. Last night the total number of cases notified had risen to 1,642 and the deaths to 91. The rate of increase has some days seemed less and inspired hopes of a rapid decline which have been disappointed. On Monday the cases were 1,574, of which 20 were new. On Tuesday the number rose to 1,593, Wednesday to 1,620. From September 18th to 21st the attacks were at the rate of 82.7 per diem; for the week ending September 28th at the rate of 74.4; for that ending October 5th, 69.4; October 13th, 26.4. There is so great distress in consequence of the epidemic that subscriptions have been opened in various towns to help. The Lord Mayor of London has also opened a fund.

I mentioned that the water company was to discuss the disinfection of the Farleigh mains. On Monday it was determined that this should be done on Wednesday or Thursday, but the work has not been done. The town is now promised that the disinfection shall be carried out between to-morrow and Monday, and the inhabitants naturally want to know why it was not done three weeks or more ago. It is now to be done under the supervision of Dr. Sims Woodhead. It is proposed to mix eleven tons of chloride of calcium with 225,000 gallons of water and pass the solution through all the pipes supplied by the Farleigh Springs. So simple an operation as this could surely have been adopted at first, and the water company has much to answer for without adding to its faults this delay. There is an outcry for governmnent investigation and confiscation of the monopoly, a demand which meets with sympathy wherever people feel themselves at the mercy of water companies. Dr. Semple inoculated eighty of the attendants in the asylum with the vaccine prepared at Netley. Some of the nurses in the town also submitted to the experiment, but very few of the inhabitants. Forty medical men and more than one hundred nurses are engaged in the town. I regret to hear that Dr. Semple is ill with Malta fever contracted during his Netley experiments.

London has been alarmed by reports of cases imported from Maidstone, and much has been made during the week of the occurrence of cases in University College Hospital, where too great reticence was observed toward the press; but typhoid does not appear to have been in excess of the average in London at this season. The alarm will be productive of good if it rouses the public to the disgraceful state of the River Lea, from which East London draws water. The company is warned that there is great danger from this source, and neglect on its part will be severely visited.

The cases at University College Hospital have been confined to certain nurses and wardmaids. In the course of rebuilding-operations their dining-room had to be demolished. In the one to which they were removed a different water supply was used, and this had become contaminated from a tank in which soiled linen was soaked before boiling. About eighteen cases have thus occurred, but the source of infection was soon traced and cut off.

The societies are at work. Last week the Obstetrical and Clinical held meetings. This week the Medical met on Monday; yesterday the Gynæcological and the Society for the Study of Inebriety. The Pathological is to meet next Tuesday.

The new president Dr. Sansom took the chair at the meeting of the Medical Society and discoursed on nervous disorders of the heart not associated with obvious organic lesions, and urged that such abnormal conditions should be more carefullly observed and examined in a methodical manner. Among symptoms often met with in functional cardiac disturbance he mentioned protuberance of the eye, inharmonious action of the muscles of the globe, retraction of the upper lid, inequality of the pupils and other eye symptoms. Auditory signs, the pulse, and muscular tremors were also to be noticed.

The mechanism of cardiac dilatation and the significance of systolic murmurs at the apex or near it were further considered.

A very interesting—not to say amusing—paper followed by Mr. Anderson. It was a biographical sketch of John Anderne, born in 1307, and accepted by Mr. Anderson "with pride and veneration as the father of English surgery." Lovers of early medical literature will be delighted with this paper.

At the Clinical Society meeting the new president, Mr. Langton, thanked the fellows for the honor they had accorded him of succeeding the late Mr. Hulke, whose office he had temporarily occupied in consequence of the latter's lamented decease. He then remarked on the history of the society and the work it had done, especially in the last two years. In illustration of the value of its work he instanced the report on myxœdema, which elucidated the pathology of the disease and even led to the discovery of its successful treatment. Another piece of work was that done in connection with the vermiform appendix. He mentioned that at St. Bartholomew's Hospital operation on this organ had been done in fourteen cases during the last year, in all of which the patients had recovered. In ten of these there was suppuration, in four inflammation. He promised to give the usual inaugural address at the first meeting of the coming year.

A case of Loreta's operation was then related by Dr. White and Mr. Langton, after which Dr. Phear read an account of a case of cerebral sinus thrombosis in a child of seven. There was an interesting discussion on each of these cases.

Dr. Alex. Hill has been appointed vice-chancellor of the University of Cambridge—the highest executive office. Dr. Hill is the lecturer on advanced anatomy and has been Hunterian professor at the College of Surgeons. He will be known to you as an eminent neurologist, the author of the "Physiologist's Note Book" and numerous papers on the anatomy and physiology of the nervous system.

Dr. Hicks, the newly-appointed bishop of Blömfonstein, is a well-kown medical man and author of a "Standard Text-Book of Inorganic Chemistry."

Mr. Ernest Hart's convalescence has continued, and he has left town for Brighton.

Frederick William Barry, M.D., D.Sc. Ed., F.B.S. Ed., D.P.H. Cantab., the senior inspector of the local government board, was found dead in his bedroom at Birmingham Hotel on Tuesday. He arrived the evening before in order to confer with the board of guardians. He was the writer of numerous important reports in the course of his duties on cholera, vaccination, fever, and other matters relating to the public health. He was government sanitary commissioner in Cyprus from 1880 to 1882, a member of the Epidemiological and other societies and also a barrister of the Middle Temple. At the inquest a verdict of death from natural causes was found. Dr. Barry is deeply regretted in the health service and by all who knew him.

Dr. Rob. Smith, medical superintendent of Gateshead Aslyum, died under chloroform last week in the Stockholm Hospital, to which he had gone to have an operation performed for fistula. He was M.B. Aberd. 1854, M.D. 1858.

Dr. James Long, a retired deputy inspector-general, was found dead in his sitting-room on Friday. The body was under the table in a position to which it might have slipped. He lived quite alone. He was M.D. of Edinburgh, 1850.

"Dear old Dr. Wickham," of Tetbury, Gloucestershire, died on the 30th ult. in his ninty-fifth year. He went to Tetbury about fifty years ago.

OUR PARIS LETTER.

(From our Special Correspondent.)

DUSTS AS PROPAGATORS OF INFLAMMATORY DISEASES —DONATION TO THE FACULTY OF MEDICINE TO FOUND THE LEGROUX PRIZE—TRANSMISSION OF MUMPS TO THE DOG—ABDOMINAL SURGERY—CYON'S NERVE—FLOATING KIDNEY AND VIBRATORY TREATMENT, ETC.

PARIS, October 22, 1897.

THE rôle played by dusts of different kinds as factors in the causation of disease is more important than is generally admitted. The metallic dusts, by their irritative action upon the membranes of the finer bronchial tubes, frequently give rise to bronchitis and pneumonia; and all are familiar with the calico-like appearance of a lung impregnated with coal-dust deposit. But it is to other dusts than these that are due many cases of eruptive fevers, diphtheria, pneumonia, and almost always tuberculosis. We refer to the dusts that are concealed in the cracks of floors, along the cornice, on the tops of window-frames, and in the angles of walls. It is for this reason that modern hospital wards should be built with rounded corners and vaulted ceilings, without cracks or confractuosities of any kind.

By decree, the Faculty of Medicine is authorized to accept the donation of a sum of 10,000 francs, made in its favor by Madame Legroux for the foundation of a prize to be given every five years under the name of the Charles Legroux prize. The prize is in perpetuation of Dr. Charles Legroux's memory, late professor *agrégé* at the Faculty of Medicine of Paris.

There have been several important and interesting communications made recently at the Academy of Medicine. In the first instance, Dr. Laveran related a curious observation of the transmission of mumps from man to the dog. It should be noted, however, that Dr. Laveran made this communication on behalf of Dr. Busquet, of Bordeaux, adding that, although Dr. Busquet thought he had observed such transmission, it seemed to him (Dr. Laveran) not probable.

The military doctors took part in the proceedings. Dr. Moty entertained the academy on the accidents of the wisdom tooth. The word "accidents" is given in the French sense, meaning diseases and their complications.

Dr. Chauvel confirmed with two observations—the one by a successful operation, the other by a death—the necessity of immediate intervention in all cases of penetrating wounds of the abdomen. He advocates opening at once the abdomen, suturing the intestine, and washing the peritoneum. This is the ground taken by some of the leading American surgeons many years ago. Sims was among the first to propose it, and although the operation was talked of in Garfield's case it was unfortunately not undertaken. With our modern system of antisepsis, the abdomen could be opened in all cases of penetrating wounds, certainly without increasing the already existing danger. Not only does the surgeon thus become doubly sure of his diagnosis, but the chances of the patient's ultimate recovery are largely increased thereby.

All heart specialists are familiar with Cyon's nerve —a sensitive nerve of the heart by which that organ provokes a reflex action dilating the peripheric circulatory system and thus diminishing the energy and number of its efforts. Dr. Cyon, who was for some time editor-in-chief of a Paris newspaper, is now discoursing at the Academy of Sciences on the thyroid gland and iodothyrin, the product of its secretion, with reference to the treatment and cure of exophthalmic goitre. It is strange in so learned a body as the Academy of Medicine, that is intended to represent all branches of medical science and practice, how rare the neurologists are! The vast and magnificent department of nervous pathology has as yet no special section. Certainly the academy should create one and admit into its ranks Professors Raymond and Joffroy, also (*agrégés*) Professors Brissaud, Dejerine, and Gilbert-Ballet, none of whom, although leading lights in the world of nerves, is a member of the Academy of Medicine.

Dr. Ferrand is one of the most active neurologists now in the academy. He is a spiritualist as well, and has brought his synthesis to dualism, differentiating the psychical from the intellectual functions, the faculties of the soul from the properties of the cerebral cell.

Dr. Lanceraux, who is evidently an advocate of vibratory medicine, reported the case of a client affected with painful floating kidney, who one day took the train for Bordeaux, some seven or eight hours' journey from Paris, for the purpose of obtaining there a suitable bandage to support the wandering organ. After six hours of railway travel, she experienced a cessation of the pain and a return of the kidney to its customary place, where it remained for three years without occasioning any trouble whatever. The patient thought herself permanently cured, when the kidney again left its normal position. She took a second time the train for Bordeaux, and again after six hours of travel the pain ceased, the tumor in the right hypochondrium disappeared, and the kidney returned *in situ*.

We had already the vibratory helmet and chair of Charcot, such excellent remedies in the treatment of neurasthenia, but should be at a loss to account for the happy action of trepidation in this case, unless we accept Cheron's idea that floating kidney is a ptosis of neurasthenia, and the trepidation or vibration acted as a stimulus to the nerve cells—a treatment that is certainly indicated in neurasthenia.

The trial of Dr. Laporte, who recently performed craniotomy with a mattress needle, began yesterday. The operation, it will be remembered, was followed by the death of the mother as well.

OUR BERLIN LETTER.

(From our Special Correspondent.)

THE NEW ORDER IN OUR UNIVERSITIES—THE INTERNATIONAL MEDICAL CONGRESS IN RUSSIA.

BERLIN, October 1, 1897.

THE German ministry has formulated a new rule governing the study of medicine in all the allied German States. This has already been made public by means of the telegraph, but it is of such vital importance to Americans studying in Germany that I may be excused for dwelling upon it at length. It has been ruled that only such persons as have passed the preparatory medical examination in Germany, or one similar thereto in other countries, may be admitted to visit and study at the clinics, etc. As a degree from a German college (gymnasium) is required of all candidates for the "*testamen physicum*," and as there exists in America no arrangement corresponding to the German "*physicum*," the importance of this new law is very apparent, for it excludes Americans from clinical studies in the German States. This bureaucratic ruling is, however, a double-edged sword. It serves the good purpose of excluding from our universities the unworthy element which has heretofore brought such disrepute to the German medical title; on the other hand, it at the same time excludes the good and desirable element whose purpose in coming here is to further medical knowledge. Germany will suffer in consequence, for as a natural result Americans and others affected by the new law will visit other countries.

The medical post-graduate courses are in no wise affected. Many of the Americans who attended the Moscow congress are at present actively attending these courses.

As the scientific proceedings of the congress are to be reported by the international press bureau of the congressional committee, I will omit any mention thereof and speak only of the open arrangements and public proceedings. I will begin by stating that at no previous international congress was there such perfect organization as at this one. Government and private individuals vied with each other in trying to add to the pleasures and comforts of the foreign guests, to make their stay in Russia memorable.

The granting of a free railroad ride, in first-class compartments, from the border to Moscow and thence *via* any selected route to Petersburg and return to the border —an allowance never yet made by any other government—secured the good will and the good humor of the guests. A nod from one high in authority (in Russia always a magic talisman) relieved us from all those inconvenient and vexatious passport and customs difficulties one encounters nowhere so ubiquitously as in Russia. In fact, there was a marked absence of customs revision. We Europeans, who are not so accustomed to long-distance travelling as our American colleagues, regarded with horror the thirty-hours' ride *in prospecto* from Warsaw to Moscow. It was a most agreeable surprise to us, therefore, to find ourselves at our journey's end in nowise tired out—in fact, in very fresh condition, so excellent and comfortable are the Russian railway coaches, which are in this respect as well equipped as the American. The excellent railway restaurants added not a little to our comfort.

Delegates from the congress accompanied all trains and also met them at the railroad station at Moscow, where each visitor was assigned his quarter and given all necessary directions and help. Many lived gratis in the clinics, which were empty on account of the vacation; others with Russian colleagues, especially the professors; the majority, however, located at hotels and private residences at remarkably low prices. The committee had a list with prices, thus excluding any extortion.

The headquarters were at the "Manège," in the very centre of the city. Here one learned details about the sessions, the arrangements for the festivities, excursions, city attractions, etc. The national committees had their bureaus here, one met acquaintances or formed new ones, got general information, obtained return tickets—in short, it was the place where all concerned met and obtained or learned what they wished. This arrangement was an ideal one. Everything was well regulated—no confusion, no crushing, no pushing or rushing, as was the case in Rome; everything went along smoothly. Male and female students, most of them speaking English, French, and German, did voluntary service and proved very useful. Every participant in the congress received gratis a "Guide to Moscow" in French, and there was issued almost daily a French journal. The official programme was also made public here.

The general sessions—there were three in all—were held at the Imperial Theatre, an immense building with a seating capacity of three thousand. Each session could be attended by about one-half of the total number of members. The first one, which was opened by the uncle of the Czar, was most brilliant; the foremost members of the profession in the entire world were present. The greatest honors were paid to Virchow, an almost unceasing applause greeting his every appearance upon the platform. Section meetings were held at various buildings not widely separated, and those intimately associated were when possible assigned to the same building—for instance, general medicine and general surgery in the Adels Club, a magnificent edifice. Many sections were held at the old and new universities and at the principal clinics. In spite of the heat the attendance was very good. Proceedings were held mostly in the German language; English and French were also employed; Russian very little. The French complained later in their professional papers about the prevalence of German; in spite of their alliance they felt themselves set back. I believe their complaint is unjust, the Russians being unbiassed in their hospitality. We cannot blame them for feeling more closely in sympathy with their German colleagues, who are in a great measure their teachers. Their text-books are German or translations thereof, and the number of Russian physicians studying in Paris is very small compared with the number of those in Berlin.

The hospitality of the Russians is beyond praise; classical in fact. Delightful beyond description were the festivals given by the city of Moscow, by the physicians of Moscow, and by the different colonies. At one affair fourteen thousand guests, including representatives of the city itself, were present. Until 3 A.M. there prevailed the greatest good-humored animation —this in spite of the babel of tongues and the large attendance. A moderate estimate would place the expense of this festival at not less than $25,000. There was such a superabundance, that late at night when the guests departed the tables were still loaded with eatables. For the eye, the ear, and the tongue, there was more than enough. So with all the festivals. Special thanks are due to the Russian ladies who looked after the comforts of the female guests. They were most amiable, and their efforts were entirely successful.

A word about Moscow itself, for with the exception of Rome no city of Europe presents so much of historic interest. In spite of the great destruction by fire of its older churches, there still are many which date their existence back eight hundred years or more. The Kreml, with the coronation cathedral, the imperial palace, and the treasure chamber, in which latter

are kept the coronal insignia of all the crowned monarchs of Russia and where are immense quantities of jewels and gold, offer enough of interest to the visitor to occupy several days. When one considers in addition the other interesting churches and monasteries, the museums, picture galleries (including the Tretiokoff, in which most of Verestschagin's are to be seen), the unique foundling and lying-in house, the curious streets and pretty parks and squares, it will be easily understood that the congress members could well employ the time left them outside of the section meetings.

Bodily wants were also well provided for; the Russian cuisine is excellent and the prices are moderate. One soon learns to eat caviar and to drink tea. The pavements are miserable, but carriage hire is so cheap that riding is no costly luxury. The drivers—isswoschtschiks—are an institution peculiar to the country itself. There is no fixed tariff, so one must bargain beforehand in engaging a droschke (carriage). It is the rule to give only one-half of the price asked by the isswoschtschik. The latter is a model of patience; no matter how much you scold him, he is always polite and quiet.

A bird's-eye view of the city makes a panorama never to be forgotten—one gets such a view from the bell tower of the Kreml in the centre of the city, or from the "sparrow hill" at the southwest border of the city. Every member of the congress has in all probability visited at least one of these lookout points. Though numbering not more than one million inhabitants, Moscow is much spread out. The dwellings are low and broad; churches, monasteries, parks, and squares are in large number. Here and there the blue, green, and golden tower of a Greek Catholic church stands out proudly above this vast sea of houses. Each nationality has its peculiarities; the Russians are marked by their hospitality and outward piety. This first quality has succeeded in making the Twelfth International Congress memorable to those who attended. St. Petersburg, ranking with the large American cities as a very modern city, is a jewel in the diadem of modern Russia. We cannot but speak in warmest terms of praise of the Russian government and people for their grand reception of us all.

In the next letter I report on the "Lepra-Conferenz," which has taken place here in the last few days.

BOVINE TUBERCULOSIS.

To the Editor of the Medical Record.

Sir: A few years ago we were surprised and alarmed by the discovery that a large number of the dairy cows of this country and Europe were affected with bovine tuberculosis. The public was much excited, and I believe that most of the diseased cows were destroyed and the expenses added to our already overburdened tax list. And there the matter seemed to have ended, so far as the institution of any preventive measures was concerned.

Since that time during my summer vacations in all parts of the United States I have endeavored to find out the cause of bovine tuberculosis, and the answer has invariably been "over-milking," viz., not allowing the cows any rest during pregnancy, but milking them from one year to the other until they die. In many instances I know this to be true, as the farmers have assured me that their cows never "went dry;" but these same farmers would never allow their own children to be nursed during their mother's pregnancy.

I am assured that bulls, steers, and unimpregnated heifers never contract tuberculosis.

That there are other secondary causes, such as too close confinement in warm houses or stables, I have no doubt; but the primary and principal cause is as I have stated above, and it must and will be remedied; not by forever killing the cows as they develop the disease, but by removing the cause.

The law should compel every farmer or dairyman to allow his cows to go dry for the last three months of gestation.

This is a very important matter, and I hope that other physicians will investigate for themselves.

John H. Trent, M.D.

[illegible]

THE ALTERNATIVE OR "RECURRENT TREATMENT" IN RETRODEVIATIONS OF THE UTERUS.

To the Editor of the Medical Record.

Sir: In my recent paper on "Retrodeviations of the Uterus," the following heads were elaborated: (1) Retrodeviation, *per se*, does not always give symptoms, although favoring the congestion which does give them. (2) As the congestion gives the symptoms, it is more important to remove this cause than to anchor the womb forward. (3) Every case will therefore be helped by "treatment" removing this cause, even though ultimately an operation is required. (4) Many cases, if not most cases, will lose symptoms under comprehensive treatment (including reparative work), even though the womb remains to the rear. This relief from symptoms usually continues for a period varying in length. It may be only three months; it has frequently been five years. In favorable cases "recurrent treatment" is a reasonable alternative to be weighed before selecting any of the operations, considering their drawbacks. By this is meant a few weeks of treatment each year, or every two or even five years. (5) When the periods of relief are too short, or when nothing but the rear position of the womb prevents recovery, unquestionably operation should be done—but never as routine, ignoring the safer, cheaper, more comfortable alternative. (6) The malady called retrodeviation is a complex one, always including pelvic congestion, and frequently general enteroptosis or downward displacement of the abdominal viscera. Sewing the womb forward will not always cure it. If surgery is the only resource for the condition, anchoring the kidneys will be the next amendment to the present operations.

Edebohls strongly supports my view in his experience, though we shift, and deduce differently therefrom. His paper, "Shortening the Round Ligament," gives a most complete *résumé* of its subject and a comprehensive bibliography. In addition are tabulated one hundred and fifteen operations by this painstaking surgeon. The results are most frankly given. Seventy-seven were uncomplicated anatomical successes. Thirty-four were complicated successes; that is, cases in which there were suppurations, tearings of the ligament, opening of the abdominal cavity, hernia, floating kidneys, or trouble with the appendages existing at the time of the operation or discovered thereafter. These complicated cases, added to the uncomplicated cases, make one hundred and eleven final anatomical successes out of one hundred and fifteen operations. Few surgeons can point to a better record. He writes:

"The frequent association of movable kidney or kidneys and retrodeviation of the uterus has been observed by the writer since 1890, and it is drastically illustrated by the recorded observations made in the one hundred and fifteen cases tabulated. No less than twenty-five patients are noted as suffering from movable kidney or kidneys, either existing at the time the round ligaments were shortened or developed (discovered [?]) after the operation. Of these twenty-five

patients with movable kidney or kidneys, eleven were cured by right nephropexy and two by bilateral nephropexy."

It will be seen that Edebohls has already amended the Alexander operation by the addition of nephropexy. He further says:

"While the anatomical results may be thus readily and succinctly stated, an accurate report upon the therapeutic results becomes a more complicated matter. The less searchingly we cross-question our patients, . . . the more likely are we to record a large number of therapeutic successes. But closer investigation often reveals one or more stumbling-blocks to perfect satisfaction, in the shape of complicating diseases present at the time of the operation or developing (discovered [?]) soon thereafter, which complications more or less fully, more or less permanently, mar the therapeutic result."

This is but another way of saying that even though the womb is safely stitched forward by a competent surgeon, the condition is not always cured.

All the special surgical devices for retrodeviation have drawbacks. To hide them, to evade their discussion, is not only unscientific but unfair. These drawbacks are entitled to serious consideration in weighing the alternatives, operation *versus* "recurrent treatment"—both involve so much time, so much money, so much disability; and there is a balance to be struck.

The Alexander is the least objectionable of the operations, but "recurrent treatment" is better, cheaper, safer, in all cases in which it gives the therapeutic results. Of course it cannot compete in anatomical results.

EUGENE COLEMAN SAVIDGE, M.D.

60 WEST FIFTIETH STREET, NEW YORK.

EXPERT EXAMINATION FOR TESTAMENTARY CAPACITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Quite recently there has been no small amount of litigation, in the courts of this district and presumably in the courts of other districts, regarding the validity of wills. In the vast majority of these cases the ground is taken by the plaintiff that the testator was *non compos mentis* at the time of the execution of the will in question. Some endeavor to establish that, while the testator may not have been actually insane, yet the mental faculties were in a state of mild degeneration or something of that nature, so that the testator was abnormally susceptible to the influence of interested parties. It often happens, too, that the cause of death of these people who have left unsatisfactory wills is due to some disease other than that of the mind or nervous system. The physician who attended perhaps saw no need of a thorough examination of the nervous system—certainly did not examine it with a view of establishing the competency or incompetency of the patient to execute a will. As a result, the physician, when called to testify, is not infrequently unable to set forth the case with that clearness which would obtain had he deemed it necessary to examine the nervous system with reference to its stability or instability.

In view of these undisputed facts, the conviction forces itself upon me that a pathological condition of existing laws is the real cause of this diseased condition of affairs.

A law should be enacted providing in the main as follows:

1st. The intending testator must, on the same day on which he proposes to make his last will and testament, be carefully examined by a reputable physician of at least three years' practice, as to his sanity and ability to execute a will understandingly. If the testator is found to be possessed of his normal faculties and able to execute a will understandingly, the physician shall so certify in his own handwriting. This certificate must be sworn to before any person empowered by law to administer oaths for general purposes. The signature to the certificate must also be witnessed by two persons who can write. This certificate is then to be attached to and become a part of said will.

2d. In case the testator, at any subsequent time, desires to change his will, a physician must re-examine and certify as before.

3d. In cases in which it can be shown that the circumstances connected with the making of the will were such as to render the presence of a physician impossible, or when, the physician being present, the condition of the patient precludes examination, then the will must be reduced to writing and may be considered valid without a physician's certificate. Even in these cases the physician should hastily examine as best he may, and certify, if he so believes, that to the best of his judgment, knowledge, and belief the testator is in full possession of his normal faculties and entirely capable of executing a will understandingly.

Exception: This law shall not apply to wills which in the aggregate bequeath real or personal property, or both, less in value than $500.

I do not wish to be understood as taking the ground that the attachment of the physician's certificate is to render a will incontestable, but I do affirm that the existence of the certificate would in the vast majority of cases be considered too great an obstacle to surmount, and so prevent litigation. The absence of this certificate, however, should in every case, except as mentioned above, render a will absolutely null and void.

The only objections to which this system might give rise would be the extra trouble and slight expense incurred—objections which, when compared with its advantages, appear very insignificant indeed.

The conveyance of real estate by deed requires an acknowledgment under oath from the conveyer. Is the conveyance of real estate by will any less important?

A. C. MATTHEWS, M.D.

Wounds of the Air Passages.—1. Suicidal wounds of the throat should be treated by primary suture in all cases in which the general condition of the patient permits. 2. Antiseptic precautions are most important. 3. If necessary, chloroform should be administered, and is perfectly safe. 4. Divided muscles should be sutured, and in bringing together the edges of the skin the inversion caused by the platysma muscle should be corrected. 5. The wound in the air passage should be completely closed. 6. In many cases it is quite safe to dispense with the use of a tracheotomy tube. If a tube be deemed necessary it should not be introduced through the suicidal wound in the air passage, but through a fresh vertical cut at a lower level 7. Silk is the best material for suturing the larynx or trachea. 8. During the after-treatment it is unnecessary, except in certain special cases, to feed by a tube or by the rectum. 9. If the above methods of treatment be adopted, not only will a very large proportion of even dangerous and extensive wounds of the air passages recover, but the period of recovery will be greatly shortened, the patient will not be exposed to the same risks of secondary inflammatory complications, and he will be much less liable to the occurrence of permanent stenosis of the trachea or the formation of an aerial fistula.—PLATT, *The British Medical Journal*, May 8th.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 30, 1897:

	Cases.	Deaths
Tuberculosis	198	106
Typhoid fever	24	5
Scarlet fever	109	14
Cerebro-spinal meningitis	0	4
Measles	149	7
Diphtheria	145	15
Laryngeal diphtheria (croup)	1	2
Chicken-pox	7	0

Medicine for "Threading Ideas."—According to a French paper, an American physician advises students to combat the nervous asthenia which paralyzes their faculties and causes them to lose the thread of their ideas by taking ten drops of tincture of gelsemium three times a day. For the same purpose an English specialist prescribes wine of opium to be taken by actors and singers before going on the stage. From five to six drops he says will give to the most timid actress the self-possession of the most spirited old player.

Abuse of Alcohol.—Speaking of the abuse of alcohol, M. Van den Corput, at the International Congress on Drink lately held at Brussels, said it was the direct outcome of the storm and stress of life under the conditions created by modern progress. Neuropathy was a sign of the times, and the remedy for this was intelligent feeding with the use of beverages, such as sound and generous beer, milk, tea, coffee, etc.

Suicide by Hanging.—Professor Brouardel remarks that suicide by hanging has a peculiar fascination for dipsomaniacs, children, and, generally speaking, all persons whose intellects are weak or undeveloped. He says: "In some families self-murder by hanging would seem to be a hereditary failing. Not far from Étampes there is a large farm with which I am acquainted. One day, without any apparent cause, the proprietor hanged himself, leaving a family of seven sons and four daughters. Ten out of the eleven subsequently followed their father's example, but not until they had married and begotten children, who in turn all likewise put an end to themselves with the cord. There is now but one representative left of this remarkable group, an old man of sixty-eight, who has passed the family hanging-age."

The Sale of Ice Cream in Glasgow.—The Glasgow municipal authorities deal with the ice-cream vendors in that city in a somewhat novel way. Some few years ago the city fathers, alarmed at the amount of sickness, especially typhoid, clearly traceable to the consumption of ice cream, attempted to place ice cream in the same category as milk. Their efforts at first were unsuccessful. However, resolved not to be beaten, they obtained special powers, and now the sellers of ice cream in Glasgow, alone of all cities, are under the same regulations as those which control the dairies. If the example of Glasgow were to be followed in more than one of the cities of America, the result might be for the public good.

Headaches, if due to pelvic disturbances in the female, are usually located at the top of the head and are accompanied by soreness of the scalp; if due to digestive disturbances, they are occipital or frontal; if to disease of the pharynx, they involve the entire vault, as though the pharynx were expanded and extended upward; if due to migraine, they are usually one-sided, local, and accompanied by soreness at the supra-orbital foramen; if to eye strain, generally superciliary or frontal, sometimes occipital; if to disease of the nares, between the eyes and extending backward.—Dercum.

Treatment of Epilepsy.—Opium, beginning with five-sixths of a grain daily, distributed in three doses, and steadily increased until four or five grains daily are administered. At the end of six weeks the opium is stopped, and bromides are used—in large doses, seventy-five to one hundred grains a day, for a period of at least two months. The fits generally yield to the first dose of bromide. The treatment should be adopted only in chronic intractable cases of epilepsy in which the administration of bromides alone has failed. The contraindications are the status epilepticus, plethora, and cerebral focal lesions.—Flechsig.

How Does Malaria Enter the Human Body?—The mosquito, as is well known, deposits its eggs in water or in damp places; from the eggs are hatched larvæ, which, very voracious, devour everything they encounter, among other things the bodies of the dead mosquitoes and the envelopes from which they have emerged. They then pass into the state of nymphæ, from which emerge the young mosquitoes. During this long period of life in damp soil or in water, and especially in the state of larvæ, one may imagine that they load themselves with malarial germs, which everything leads us to believe are found most abundantly in the soil, and which afterward in the last period of life, when the female mosquitoes live as suctorial insects, might inoculate man. This hypothesis would naturally give rise to other problems. The malarial germs, having entered into the young larvæ, might live in them as parasites, going through a necessary stage of their life in this host before arriving at man. On the other hand, one might suppose these diptera to be simply carriers of the germ into man.—Bignami.

Is Crime a Disease?—Of 394 thieves, 74 are dolichocephalic, 129 mesocephalic, 191 brachycephalic; of 107 homicides, 21 are dolichocephalic, 31 mesocephalic, 54 brachycephalic; of 92 sexual offenders, there are 18 dolichocephalic, 30 mesocephalic, 38 brachycephalic; of 54 swindlers, there are 9 dolichocephalic, 15 mesocephalic, 30 brachycephalic. A study of the individual indices shows a considerable proportion to be entirely outside of the physiologic limit. This is most marked among the sexual offenders, in whom the cephalic index was in itself absolutely pathological in about fifteen per cent.; that is to say, considering the antero-posterior diameter of the cranium as 100, then the transverse was represented by less than 76 or more than 87, the former being extremes of dolichocephalic and the latter of brachycephalic skulls. The brachycephalic skulls much predominated in the entire group of criminals.
W. A. McCom.

Diphtheria in London.—Despite the great outlay on sanitation in London, diphtheria goes on increasing in prevalence. According to the clerk of the Metropolitan Asylums Board it has been steadily gaining ground for a considerable time past, and its continuous development has puzzled all who have examined into the matter. The same increase is observed in the provincial towns, but not to the same extent. Thus in them the death rate from diphtheria rose in ten years from 0.27 to 0.38, while in the same period in London it has increased from 0.41 to 0.60 per 1,000. This increase obtains even in parts of

London otherwise creditable in their sanitary conditions. The disease is five times more fatal at present than scarlet fever, according to the experience of the Metropolitan Asylums Board's hospitals, although the mortality has been greatly reduced by the antitoxin treatment.

Sterility.—Dr. Vedder, of Christiania, Sweden, reports the results of examination of three hundred and ten married women who had never been pregnant though married at least one year. In fifty of these cases he was able to examine the husband also. He draws the conclusion that in seventy per cent. of these cases the husband is to blame for the sterility, either through impotence or through infecting his wife with gonorrhœa.—*Norsk Magazin for Lägevid.*

The Mystery of Heredity.—Out of two hundred and twenty-two pupils in the grammar schools in Chicago who attained a certain percentage of efficiency, only twenty-five were boys. This would indicate that girls are about four times as bright as boys. It is hard to understand these things and straighten up the rules of heredity. It is, we believe, the accepted rule that boys "take after" their mothers and the girls after their fathers. If they, the women, are the smarter, the boys, "taking after their mothers," should also be the smarter. If the men are the smarter, then the girls, "taking after their fathers," should be smarter. It is a difficult riddle to unravel.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended October 30, 1897:

YELLOW FEVER. UNITED STATES.

ON SOME UNUSUAL FORMS OF APOPLECTIC ATTACK.

BY M. ALLEN STARR, M.D., F.R.C.P.

NEW YORK,

PROFESSOR OF DISEASES OF THE MIND AND [illegible] IN THE COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF COLUMBIA UNIVERSITY; CONSULTING PHYSICIAN TO ST. ELIZABETH'S, ST. VINCENT'S, AND ST. MARY'S HOSPITALS, AND TO THE NEW YORK EAR INFIRMARY.

To the lay mind and to many physicians apoplexy and paralysis appear to be synonymous terms. Even in many of the text-books the varieties of apoplectic attack possible are not clearly stated. Hence it seems proper to call the attention of the profession to cases which, though exceptional, occur; and in which the sudden onset of cerebral symptoms, quite of the nature of apoplexy, is not attended or followed by any paralysis.

If a moment's consideration is given to ordinary apoplexy, it will be recalled that its chief feature is a sudden attack, usually characterized by complete loss of consciousness, in which the person falls as if struck; (ἀποπλήσσειν, to strike), and followed by more or less complete hemiplegia, which is attended by aphasia when the paralysis is upon the right side of the body. This is so commonly the history that the ordinary association of the hemiplegia with the apoplexy has led to the conclusion that such an association is inevitable. Such apoplectic attacks are usually due to a hemorrhage in the brain, or to embolic or thrombotic suspension of circulation in the cerebral arteries; although it is never to be forgotten that such a stroke may be the first sign of a brain tumor.

But the various parts of the brain differ widely in their function, and hence it is to be expected that hemorrhage or embolism will produce different effects according to the part of the brain which is affected. It is well known that hemorrhage and embolism are far more common in the domain of the middle cerebral artery than in that of other blood-vessels. And the middle cerebral artery supplies the motor area of the brain and its adjacent speech areas with blood. Hence the usual effect of a rupture or an obstruction in this vessel is the production of the ordinary form of apoplexy with paralysis.

If, however, some other vessel in the brain—the anterior cerebral artery, the posterior cerebral artery, or some branch of the basilar artery—is obstructed or ruptured, the motor area of the brain will escape, and in such a case there is not necessarily any paralysis attendant upon the attack. In such cases the local symptoms of the attack will vary according to the region of the brain affected. In every case there will be evidence of brain destruction, just as serious, just as permanent, as the paralysis attending the ordinary attack; and the prognosis regarding recovery must be as guarded and the care of the patient during recovery as rigid as though a severe hemiplegia were present. I call attention to these facts because I wish to emphasize the need of care both in prognosis and in treatment, for it has been my experience that too little importance is often attached by physicians to attacks of an apoplectic nature when it is found that they are not followed by paralysis.

The following cases illustrate the statements made:

CASE I.—Male, aged forty-one, while convalescent from a short continued fever, his only illness for several years, went to Las Vegas, an elevation of seven thousand feet, arriving in a weak condition. On the night after his arrival he awoke twice with very intense pain in the left frontal region, and was obliged to rise and pass unusually large quantities of water. On the second occasion he suddenly felt a numb sensation over the entire right side, the pain in the head became more intense, and he fell over upon his bed. He did not lose consciousness and soon got up to call some one, but on opening his door he found that he could not recollect the name of any one or speak. He made a noise, however, attracting help. When seen by a physician within an hour he seemed bewildered, talked in a rambling manner, misplacing words so that it was difficult to understand what he wished to say, but he had no paralysis anywhere. For several days this condition remained stationary, his mind being bewildered and anxious, his speech becoming, however, clearer, his chief complaint being of a sensation of numbness in his right side, which was not, however, attended by actual anæsthesia or by any paralysis. He was brought to Kansas City after two weeks, and thought he improved as he came down to a lower altitude. During the following two months there was a slow but continuous change for the better, though his memory for recent events, for things he read or heard from day to day, was wholly untrustworthy.

Examination here ten weeks after the onset showed a thin, pale, anxious, nervous man, able to tell his story slowly, with some slight hesitation for words at times, but a fairly clear consciousness of his condition. In talking the effort of attention wearied him; he would seem distressed, bewildered, and lose the thread of his conversation. He complained that he could not concentrate his attention, that it was a great effort to think, that he could not read or write without exhaustion, and that he was confused and forgetful. Yet examination failed to show actual aphasia, agraphia, or alexia; there was no paralysis, no loss of sensation, no hemiopia or deafness. The pupils were equal and normal in size and action. The discs were clear. The knee jerks were equal. There was no cardiac or arterial disease, and no nephritis. The subsequent history was one of slow improvement, and at the end of ten years he is alive and able to work, but has a feeling that his mental capacity is not so good as it was before his attack.

CASE II.—Male, aged fifty-four, previously in good health, was suddenly seized, while reading quietly, with severe pain in his right frontal region and with vertigo, attended by great anxiety and prostration. He soon vomited and had a movement of the bowels, after which he was very weak and confused in his mind and talked with difficulty. Dr. Gill Wylie saw him within an hour, found him in a state of shock, with slow feeble pulse, profuse sweat, great weakness, and extreme mental confusion; a slight left facial paralysis with deviation of the tongue to the left was

noticed. He reacted to stimulation, but for ten days appeared to be ill, was too weak to stand, and any exertion produced vertigo and nausea. He suffered constantly from headache in the right frontal region.

Examination on the tenth day showed a large, muscular, well-nourished man. Pupils equal and acting normally; discs clear, with veins rather large; very slight paresis of the left side of the face and tongue; no paralysis of the arm or leg, though the left knee jerk is greater than the right; and no anæsthesia or subjective numbness; speech clear. His chief complaint is one of great mental confusion. He cannot fix his attention on anything, and any effort to think, to read, to listen to talking, or to talk is painful, so that he feels completely incapacitated for all mental activity. This mental feebleness is in striking contrast to his physical condition. He does not trust his memory or judgment, and is much distressed at his failure of mind. This condition gradually passed off. At the end of a month there was no trace whatever of any facial paralysis and his knee jerks were equal. He still had occasional headache and vertigo on any physical effort. Slowly his feeling of mental confusion subsided. At the end of six months he was able to return to his business, and during the past ten years he has had no return of his symptoms and no recurrence of the attack.

Case III.—Male, aged sixty-seven, who had been failing in vigor and in mental power for three years, was suddenly seized with an attack of great weakness, prostration, and confusion of mind and distress, attended by great difficulty in respiration, inability to inhale, with apparent obstruction at the larynx. He was seen by Dr. R. P. O'Neill, who found a weak, slow, intermittent pulse; irregular respiration, much labored; profuse, cold perspiration; and a marked mental confusion and a slight weakness of the left side of the face. From this attack he gradually recovered, but he has never been well. He has no control over his emotions. He cries or laughs indifferently when he talks, there being no actual connection between the train of thought and the emotional exhibition. To ordinary questions he replies intelligently, but his memory is poor for recent events, his judgment is weakened, he has no confidence in his own mental actions, appeals constantly to his wife for correction of his statements, and his emotional instability is most painfully apparent. He laughs at nothing and cannot stop, or he cries and sobs and recovers his composure with much difficulty, complaining that he cannot control himself, and yet that there is no occasion for this evidence of emotion. There is no corresponding mental state of amusement or of distress. The emotional act is as uncontrollable as a convulsive twitching or spasm would be, and equally without intention. There is no paralysis, there is no sensory disturbance except a subjective tingling of the left hand. His knee jerks are increased. There are no cranial nerve symptoms.

This patient has been under my observation for the past four years, during which his condition has been practically stationary. He is more feeble, has to make a great effort to talk aloud, and has never recovered his emotional control to any degree, but he has had no attacks and he has no paralysis or disturbance of sensation. His blood-vessels are rigid and his heart is weak and at times intermittent.

Case IV.—Female, aged fifty-two, had suffered from trigeminal neuralgia for many years at intervals, but was otherwise in fairly good health without evidence of nephritis or cardiac disease. On the 12th of June it was noticed that she was unusually drowsy and dull during the morning, and this drowsiness gradually increased to a state of semiconsciousness, in which it was difficult to arouse her attention or to make her move. This was associated with a very great contraction of the pupils, with superficial rapid respiration, and a feeble but not rapid pulse. There was no apparent paralysis, but there was no control of the sphincters. For thirty-six hours she remained in this condition, there being no rise of temperature, and then the stupor became somewhat less, but she could not be aroused sufficiently to talk intelligently. There was no apparent loss of sensibility, but the left side of the face was slightly flattened and the left side of the tongue was partly paralyzed. The pupils were less contracted; pulse, 78; respiration, 24; temperature, 99° F. She was able to swallow, but still allowed everything to pass from her without notice. During the following week there was a gradual but steady improvement in the condition. She became brighter mentally, conscious of her surroundings, recognized her family, was able to answer questions intelligently, but slept most of the time when not actively aroused by the nurses. By the end of two weeks but little trace was left of the facial paralysis and the tongue no longer deviated; the pupils had come to their normal condition, reacted perfectly; there was no evidence of congestion of the retinal vessels; the motion of the eyes was perfect, vision good; there was no deafness, no anæsthesia or paralysis in any part of the body; and from this time there was a gradual but steady recovery of health, until she returned to her previous normal condition. It is thought, however, by her family that she is a little less active mentally, that her memory is not quite so reliable, and that her emotional control is somewhat defective, as she becomes excited and irritable more easily than formerly and shows more emotional excitement upon little provocation than she did in a state of health.

I think it is evident from these histories that attacks quite of the nature of apoplexy occurred in each case, but not attended by paralysis of a permanent or very noticeable character.

The location of the lesion: In these four cases the location of the lesion was probably in the frontal lobe of the brain. This was evident from the location of the sudden severe pain in the frontal region and upon the side of the lesion, from the symptoms of slight confusion of speech and slight facial paresis of temporary character, and more especially from the mental symptoms. It is an accepted fact that mental confusion and dulness, an inability to concentrate the attention, to pursue a train of thought, to exercise self-control, and to conduct the highest mental processes are almost uniformly produced by lesions in the frontal lobes.[1] These were the most marked symptoms in the first three cases. An emotional condition of unusual character also points to the frontal lobe as the site of the lesion. Seguin called attention to this many years ago, and recently Brissaud[2] has confirmed the fact by recording a number of such cases. It seems to be more commonly caused by lesions of the right frontal lobe, and hence is often associated with left hemiplegia in patients who are paralyzed. The condition is one of a more or less complete loss of control over the outward manifestations of the emotions, so that crying or laughing without cause is observed, and the patients admit that they do not know why they are showing such emotion and cannot help it. In all these cases the lesion must have been in the domain of the anterior cerebral artery.

In the following cases somewhat different symptoms were manifested:

Case V.—Male, aged fifty-four, was suddenly seized, while in the act of walking, with a sensation of numbness and coldness in the left foot, which ex-

[1] See "Contribution to Cerebral Surgery." McBurney and Starr, American Journal of the Medical Sciences, June, 1893.

[2] "Leçons sur les Maladies du Système Nerveux." Paris.

tended up the leg, involved the side of the body and the arm and side of the neck, but did not reach the face. It was not attended by any loss of consciousness, pain, vertigo, or sense of prostration, and he had no feeling of weakness. When I saw him three months later the sensation of numbness persisted and was attended by a feeling of intense cold in the left leg, body, and arm, so that he insisted even during the heat of summer in having the arm swathed in cotton. He could perceive a light touch of cotton everywhere, but felt it differently on the two sides, the left being numb. The sensation of pain was less acute in his left side except upon the face. All warm objects were felt as cold, and cool or cold objects were painfully cold in the left arm and to a less intense degree in the left leg and side of the body. There was no paralysis, no loss of muscular sense. All the cranial nerves were normal. There were no general symptoms. His arteries were rigid, but the heart was not diseased. The condition remained stationary for several years.

Case VI.—Male, aged sixty-two, who has a well-marked mitral regurgitant murmur and extremely rigid arteries, suffered in 1893 from a slight attack of left hemiplegia which passed away gradually, leaving a disagreeable and permanent sensation of numbness in the left hand. During the summer of 1896 he had an attack in which he noticed a headache, a sensation of vertigo, and a sudden obscuration of vision in the left eye. This was attended by a condition of prostration, in which he was seen by Dr. W. C. Campbell, who found his heart very weak and intermittent, but his mind perfectly clear. There was no anxiety, no aphasia, no paralysis, but an examination showed that the supposed dimness of vision in the left eye was really a bilateral left hemianopsia. In the course of two weeks the general symptoms subsided under appropriate treatment, and since that time he has been attending to business. But the left homonymous hemianopsia remains, a careful perimetric diagram of the visual fields taken in October and again in December, 1896, showing that the blindness in the left half of both eyes is a permanent symptom. The field of vision is shown in Fig. 1.

Case VII.—M——, aged sixty-five, a hard-working banker, had been apparently in good health until March 14, 1897, when he suddenly fainted and had a slight convulsion. This was followed by a condition of prostration of an unusual degree, and for a week he was confined to his bed. Then, on attempting to get up and move about, he had a second slight convulsion, which is said to have been limited to the right side of his body. This attack was followed by great confusion of mind, by a slight weakness of the right hand, and a mild degree of aphasia, in which he misplaced words though he talked freely. The paralysis and aphasia had entirely passed away three days later, when I saw him, but his mental condition of confusion, inability to concentrate the attention, to give a connected and intelligent account of his condition continued, and he complained of great distress and pain all over the top of his head.

Examination showed a loud, direct, aortic murmur, and very tortuous and rigid arteries without any increased tension. There was no nephritis. He was extremely pale and mentally he was very feeble, being apparently unable to conduct a connected conversation, though his speech was in no way affected and he was not at all paralyzed. He was able to read and to write, but it was found that he could not add up figures or make ordinary computations, although this was part of his daily business. Further examination showed a right bilateral hemianopsia which had not been noticed by himself or by his physician. He was advised to remain in bed, not to exert himself in any way, and was ordered caffeine and iodide of potassium, five grains three times a day. On the 4th of April he had another attack of faintness and increased mental confusion, after which the sensation was slightly affected in the right hand and leg. He continued in a feeble condition, gradually losing weight and becoming more and more exhausted, and died the 1st of July. He never recovered his mental balance or his power of thought and judgment, and although he developed no further symptoms of the nature of paralysis, his hemianopsia and hemianæsthesia remained until the end. He died suddenly in an attack of unconsciousness.

In these cases the lesion must have been in the domain of the posterior cerebral artery. This was clearly the case in the patients who suffered from hemianopsia. It will be noticed on the chart that the hemianopsia was not exactly homonymous; that is, the field of vision differed in the two eyes. This is supposed to indicate a subcortical lesion in the course of the visual tract, as distinguished from a strictly cortical lesion in the cortex of the calcarine fissure, which Henschen has shown conclusively to be the site of the primary visual centres.[1] We may conclude

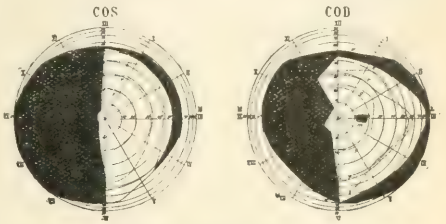

Fig. 1.—Field of Vision in Case VI.

therefore in these cases that some branch of the posterior cerebral artery passing into the base of the occipital lobe was occluded.

The course of tactile and temperature sense fibres through the brain is still not satisfactorily settled. My belief is in the existence of the cortical receptive centres for these sensations in the parietal lobe, and hence in the patient with constant sensations of cold in the arm I should locate the lesion within the parietal lobe beneath the cortex.

Case VIII.—Female, aged forty-nine, who had been decidedly nervous while going through the menopause, was suddenly seized with a sensation of numbness in the left hand, which soon extended to the left side of the body and leg, and then was felt in the right side of the face. The feeling was as if the entire left body and right face were asleep or dead, the sensation extending up the neck and over the back of the head to the vertex on the left side, and involving the forehead, face, and jaw on the right side. At the same time she noticed a ringing in the ears, a difficulty in swallowing, and when she attempted to move and to talk she found her motions awkward and some defect in the pronunciation of words. She was seen immediately by Dr. Runyon, of South Orange, who found her in great mental distress and alarm, with a weak pulse, but no disturbance of consciousness or paralysis. Her condition had remained stationary when I saw her within a week of the attack.

Examination shows vision normal in the right eye, slightly defective vision in the left eye from an old atrophy of the optic nerve, but the visual field is good. The right pupil is sluggish and does not dilate in the dark, but reacts normally, like the left, to strong light and in accommodation. The eyeballs move upward and downward well, but do not converge to near objects, and cannot be turned to-

[1] "Pathologie des Gehirns," Upsala, 1895-96.

gether toward either side beyond 20 degrees; yet each alone can be moved freely when the other is shaded, hence there is defect of conjugate action of the eyes. There is marked nystagmus on any attempt to conjugate action. In rest the eyes look forward without strabismus; there is no ptosis. She complains of a constant sensation about the eyes, "as if they were set in stone in her head." The right side of the face feels numb and cold, and tingles constantly. It is hypersensitive to touch, to heat and to cold, and to pain; any contact making the paræsthesia most intensely disagreeable. This condition extends to the inside of the mouth and to the gums, but not to the tongue. The face is not flushed or pale, and is not paralyzed. The left side of the face is perfectly normal. Hearing is normal. She complains of difficulty in swallowing, and occasionally chokes. The tongue protrudes toward the left without tremor, and her speech is somewhat thick and lisping on this account. All motions of the head and neck are perfect. Her pulse is uniformly rapid, 110 to 130; respirations are regular and normal. On the left side of the head at the back, including the neck and back of the ear, and over the entire left side of the body, including the extremities, there is a continual sensation of tingling and numbness, which is increased by any contact. There is in this region hypersensitiveness to pain and to heat and cold, and touch is said to be more keenly felt, but the æsthesiometer shows that two points are felt as one on the tips of the fingers of the left hand at three millimetres' distance, while they are felt as two at two millimetres' distance on those of the right hand. All movements of the left extremities are extremely ataxic, but there is no loss of power. She holds the hand in an awkward position, fingers and thumb being overextended. In attempts to make motions there is a lack of adaptation, it being impossible to execute any voluntary movement accurately with the eyes closed. She is not able to state in what position her fingers and hand are when her eyes are closed, and cannot reproduce in the right hand positions given to the left, though she can place the left hand at once in positions given to the right hand. She cannot distinguish with any degree of accuracy between different weights in the left hand. Thus there is a very marked loss of muscular sense in the left hand. The same condition is present in the left leg, all motions being awkward and standing being impossible. No wrist or elbow jerks; knee jerks equal and normal; no ankle clonus; no incontinence of urine or fæces; no paralysis of arms or leg; systolic murmur at apex of heart and accentuation of the second sound at the base.

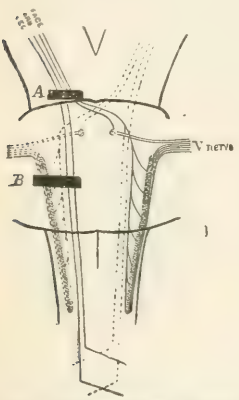

Fig. 2.—The Sensory Tract in the Crus, Pons, and Medulla, showing Nucleus and Roots of Fifth Nerve. Lesion *A* causes hemianæsthesia; lesion *B* causes alternating hemianæsthesia, right face and left side of body. Lesion *B* in Case VIII.

Three weeks later her condition was not materially changed in any way, the pulse being still 120 and the tingling being constant and almost unendurable. During the following months, however, her symptoms gradually subsided, and when I saw her one year after the attack the tingling had become less intense though it was still present; the ataxia had disappeared; the eyes could be moved in all directions well, though nystagmus was produced by all conjugate movement laterally; and her pulse was still rapid. She could walk well and was able to attend to household and social duties.

The diagram explains the necessary situation of the lesion in the pons Varolii in all such cases.

Cases of alternating hemianæsthesia are quite rare. I have recorded two.[1]

To these cases I add two cases of cerebellar apoplexy:

Case IX.—Male, aged seventy-three, was suddenly seized on July 10, 1895, with vertigo and soon after with headache and vomiting attended by great prostration. The latter symptoms gradually subsided and after two weeks he was able to be up and about, but he has suffered ever since from vertigo and he staggers in walking. He is never dizzy when lying down or when seated quietly, but as soon as he attempts to walk he becomes unsteady, feels as if he were going to fall, and in his attempts to steady himself sways somewhat from side to side and walks with an irregular gait which resembles exactly the gait seen in cerebellar disease. Any physical or mental exertion will increase the staggering and the vertigo. He occasionally suffers from a sense of pressure and fulness in the back of the head and from headache, and when these symptoms are present he staggers more and his legs feel heavy. He has no trouble with sight or hearing. His ears are normal. His digestion is perfect, and there is no evidence that the vertigo is from the stomach, eyes, or ears. He has no paralysis and his knee jerks are normal. He has no sensory symptoms. For two years there has been a stationary condition, but gradually he has noticed that motion of his eyes upward causes vertigo even when he is seated.

Case X.—Female, aged sixty, had a slight hemiplegic attack in 1889 from which she recovered entirely. About August, 1893, she had a sudden attack of a cerebral nature, attended by vertigo, headache, and prostration, from which she recovered slowly, her feebleness and apparent sense of weakness being out of proportion to any actual objective symptoms. From that time, however, until I saw her with Dr. T. M. Markoe, in March, 1895, and again in October, 1895, she had suffered constantly from a sense of unsteadiness whenever she stood up or walked. There was no vertigo while she was seated or lying down, but any attempt at standing, at walking, or going up and down stairs produced the sensation of instability and uncertainty, so that she required a cane or the aid of an arm. When thus steadied she felt relieved and could walk fairly well, but without support she had a typical cerebellar gait.

The examination showed nystagmus on movement of the eyes in any direction. There was no paralysis. The knee jerks were normal. There was a loud aortic direct murmur, and her arteries were rigid. There was no condition of the eyes, ears, or stomach at all sufficient to account for the vertigo.

The diagnosis in these two cases was a small vascular lesion in the cerebellum affecting the mechanism of equilibrium, which is known to be located in that organ. The cases could not be classed with ordinary vertigo, because the vertigo was never felt when the patients were lying down or when they were seated, was not caused by gastric or aural disease, and was permanent and continuous for years. In one case it was associated with nystagmus, and in the other it was produced by looking upward. It is known that the cerebellum controls and has a close relation to ocular movements. Hence these symptoms confirmed the suspicion of the cerebellar origin of the disease. Furthermore, the characteristic gait of cerebellar dis-

[1] New York Medical Record, February 11, 1893, "Familiar Forms of Nervous Disease," Case XVII., p. 122.

ease was manifest in both patients to a marked degree. The persistence of the knee jerks in these cases cannot be asserted as pointing to a normal cerebellum. The loss of knee jerk is not a constant symptom of cerebellar disease, as has been recently asserted. I have records of twenty-six tumors of the cerebellum, in twenty of which the knee jerks were increased, in three they were normal, and in three only were they lost. The knee jerk was not lost in any one of eight cases of cerebellar tumor recently reported by Jacobson and Jamene.[1] It must be regarded as a rare symptom of disease of this organ.

The nature of the lesion in cases which are not fatal is always a matter of conjecture, as there are no positive means of differentiating hemorrhage from thrombosis. That the lesion was a vascular one in all these cases is evident from its sudden occurrence. That the attack was not the first symptom of a tumor, as it may be in any case, is demonstrated by the progressive recovery or stationary state of all the patients. The recovery does not, however, prove that the lesion was a hemorrhage and that the clot was absorbed; for in many cases of thrombosis, especially of cortical blood-vessels, the collateral circulation is so perfect that repair is quite commonly effected. Hence the nature of the lesion must be left uncertain. When such attacks occur—as they frequently do—in the course of a case of general paresis, they are due to a hæmatoma of the pia or dura.

The severity of the lesion differed in the different cases. Here the resemblance of these cases to those of hemiplegia becomes apparent. In some cases of hemiplegia the symptoms subside slowly and power returns; in others a permanent paralysis results. This is due to the extent and position of the lesion, and to the degree of damage done to the motor tract. The same thing is true in cases of apoplexy with mental or with sensory symptoms, and the fact that no paralysis is present does not argue that recovery will ensue. In the emotional patient and in the patient with hemianopsia there has been no improvement at all and never will be. The same is true of the cases of cerebellar disease. Hence caution must be exercised in giving a prognosis in all these cases. And it is well to remember that as complete incapacity for professional work or for business may be caused by a lesion of the frontal lobe causing mental weakness, or by a cerebellar lesion causing vertigo, as by a lesion of the motor zone causing paralysis or aphasia.

As to the treatment of such cases, it is to be remembered that all the precautions against allowing effort of mind or of body during the period of repair are to be enforced just as they would be in a case of hemiplegia. A hemiplegic is kept quiet for weeks after his attack. There is no reason for allowing a man with equally extensive lesion in the frontal lobe to go about because he does not happen to be paralyzed. In hemiplegia attempts to improve the condition are made by regulating the circulation, dilating the blood-vessels by nitroglycerin, and aiding the heart in cases of thrombosis and cardiac weakness; enforcing perfect quiet and using laxatives, cold applications to the head and iodide of potassium in cases in which hemorrhage is thought probable. The same treatment should be carried out in these cases. And too great care cannot be taken to prevent a too hasty return to ordinary occupations and to those business and social anxieties which tend to put a strain upon brain action or upon the cardiac and vascular systems.

Catarrhal Pneumonia in Children.—Tincture of veratrum viride in small but frequently repeated doses until the pulse and respirations are lowered.—SUTLIFF.

DISEASES OF THE MASTOID: THEIR COURSE AND TREATMENT.[1]

BY FRANK S. MILBURY, M.D.,

BROOKLYN, N. Y.

OTOLOGIST, OPHTHALMOLOGIST, AND LARYNGOLOGIST TO THE BEDFORD DISPENSARY AND HOSPITAL, AND THE NORTH BROOKLYN EYE, EAR, AND THROAT HOSPITAL.

BEFORE beginning the consideration of this paper, I wish to request your attention for a few moments to some of the anatomical features of the middle ear and mastoid.

It is an air-containing space, lined throughout with mucous membrane, and continuous with the covering of the nasopharynx and adjacent parts. Its divisions are the Eustachian tubes, the tympanic cavity, and the mastoid cells. The first is the channel of connection between the pharynx and the tympanum, and consists of two portions, the cartilaginous and osseous, the widest opening being pharyngeal and the narrowest point at the junction of the soft and the bony parts. It is from one inch to one and one-third inches long, the osseous portion constituting about one-third of its length; the two portions are formed at an obtuse angle. Its direction is obliquely outward, backward, and slightly upward. The tubal mucous membrane contains throughout a ciliated epithelium destitute of glands, the movements of the cilia being away from the tympanic cavity, thus aiding in the drainage of the tympanum and partially preventing its invasion by pathogenic organisms from the rhinopharynx.

The tympanic cavity is an irregular pneumatic space, with its longest diameters vertical and lateral, containing the ossicula; it consists of two portions—the atrium, immediately behind the membrana tympani, and the attic, which lies above the membrane. The communication between these two is quite narrow, owing to the arrangement of the ossicles and folds of mucous membrane, and therefore a slight inflammation and swelling of the tissues may easily shut off the attic space, producing interference with its drainage, this being a serious factor in middle-ear pathology. The mucous membrane lining the tympanic cavity is thin and delicate, and closely adherent to the underlying bone; its epithelium is usually tessellated, and may in places be ciliated, as is most frequently the case in the vicinity of the Eustachian orifice. A little above, continuous and posterior to the attic, the mastoid antrum is situated; it is the only pneumatic space developed at birth, the others being formed subsequently. Not infrequently a second cell of considerable size is found at the tip of the process. The mastoid process, both externally and internally, varies greatly in its construction; thus we may have those which are entirely pneumatic, those which are pneumatic and diploetic, those which are wholly diploetic, and, lastly, those which are altogether sclerotic, excepting the antrum. Zuckerkandl, in the examination of two hundred and fifty bones, found 36.8 per cent. completely pneumatic, while 42.8 per cent. were partly diploetic and partly pneumatic, and 20.4 per cent. entirely diploetic or composed of dense osseous tissue throughout. These conditions are also found to vary on the two sides, one side being partly pneumatic and the other completely so. From such examinations it is evident that a sclerotic process does occur normally and also as the result of inflammatory action. The position of the lateral sinus varies greatly in different individuals, sometimes being one inch or more posterior to the wall of the meatus; and, again, the bend of the sinus is so sharp that it extends forward so near to the posterior

[1] Read before the section on otology and laryngology at the forty-eighth annual meeting of the American Medical Association held at Philadelphia, June 1–4, 1897.

wall of the meatus that opening the antrum would be impossible without wounding this venous channel. To the operator the position of the sinus and the middle cerebral fossa is of special importance, and many efforts have been made, by the examination of specimens, measurements of the skull, and its outward conformation, to determine the location of the sinus; but all such researches have proven useless. Dr. Politzer states that in five hundred temporal bones which he examined he found the position of the sinus most favorable when the mastoid process was strongly developed and entirely filled with pneumatic cells. In these cases there is a broad space between the sigmoid sinus and the posterior wall of the external meatus, which in operating permits access to the antrum without danger of wounding the sinus. He found the relations less favorable in the diploetic and compact mastoid processes. How are we to know positively whether the process is diploetic or pneumatic? Hence for practical purposes these investigations prove as useless as others.

We will now take up the individual mastoid diseases.

Primary periostitis is very rare, and when it does occur is usually the result of traumatism or exposure, but sometimes is without any traceable cause; the latter is usually the case in persons of a cachectic condition. Only a few cases have been reported.

Secondary periostitis, however, is quite frequent, and is due to acute or chronic middle-ear suppuration or necrosis, the process extending outward from the tympanum until the mastoid covering is reached. It occurs oftener in early than in adult life, owing to the much greater liability of the young to ear disease. In acute middle-ear suppuration it is most frequent when free drainage is interfered with, as from a very small perforation badly placed, or from a possible pus retention by the blocking up of the opening with powders—as boric acid, alum, and some of the more adhesive new products. The fluid must find exit, and will do so at the point of least resistance. This may be:

1. Through the external mastoid cortex or into the external meatus.
2. Through the digastric fossa.
3. Through the roof of the antrum or the tympanic wall into the middle cranial fossa.
4. Into the posterior cranial fossa, by rupture usually, into the groove lodging the lateral sinus.

If the cranial cavity is invaded, meningitis is induced, and may be diffuse or circumscribed. In the latter the limit appears to be caused by the formation of an epidural abscess, the infectious material being walled in on all sides by adhesions between the dura and adjacent walls. Internal rupture may occur, or the free anastomosis between the blood-vessels and the dura and the pericranium may provide the channel through which the infectious material may pass to the brain, producing an intracranial abscess or a thrombosis of the lateral sinus. Unfortunately these lesions often occur simultaneously, thus greatly increasing the danger to life.

Until within a comparatively recent period the operation for acute disease of the mastoid was the principal surgical operation upon the ear. It was near the end of the fifteenth century that Riolanus proposed opening the mastoid cells; later, about the year 1655, Sir Thomas Brown advised against such a procedure; and it was not until one hundred years later that the operation was first performed by Petit for the removal of secretions. In 1776 Jasser performed the operation for necrosis of the bone with great success, but after his decease surgeons lost sight of the true indications for operating and perforated the bone for various purposes, until the death of Bergen, a noted Danish surgeon, upon whom the operation was performed for the relief of deafness and ended in fatal meningitis. This caused the procedure to fall into disrepute, and nearly a century elapsed before it was revived by Forget (1849), Follin, and Troeltsch (1859).

When there were inflammation, swelling, and tenderness over the mastoid, Troeltsch made an incision down to the bone to prevent necrosis, and if the symptoms indicated a deeper seat of the disease he perforated the bone with a blunt probe. To prevent injury to the brain or lateral sinus, he placed the instrument on a line with the meatus, and worked it forward and inward in a horizontal plane. If the cortex was thick he used a small trephine. The sinus was kept open by means of a piece of gauze.

To Schwartze is due the credit of developing the operation; by 1883 he had reported one hundred cases, which was the largest number reported up to that time.

Acute inflammation of the mastoid cells varies according to the stage in which the patient comes under observation. Acute otitis media without perforation is often accompanied by symptoms of mastoid irritation, which usually subside with slight antiphlogistic measures. In acute inflammation of the mastoid cells the prominent symptoms are: (1) Intense continuous pain over the mastoid and radiating over the side of the head and in the neck, which is increased on pressure and percussion; redness, heat, and œdema of the skin. When the abscess becomes localized the pain generally remains fixed at one point. (2) The membrana tympani appears strongly bulged forward before the pus perforates; following perforation a nipple-like projection is often found in the posterior-superior quadrant of the membrane, on the tip of which the perforation is situated. (3) A swelling and bulging of the posterior-superior wall of the canal, causing a narrowing of its lumen, and shutting from view all or a part of the membrane. These two latter points are very indicative symptoms. Free discharge from the ear exists, which rarely ever ceases while the mastoid inflammation continues. However, the only absolutely positive sign of a mastoid abscess is pus found within its interior on opening it. The temperature usually ranges from 99.5° to 102° F., but is seldom higher.

The course of the affection varies considerably in different cases—in some running to a fatal termination in a few days, and in others requiring weeks and months and possibly years before indicating positive symptoms. In chronic otitis media purulenta the extension to the mastoid is often without characteristic symptoms. The quality and quantity of the discharge varies greatly, now very slight, now copious, according as there is a narrow or a free outlet for drainage from attic and antrum. A thickened cheesy pus may exist for a long time in the mastoid cells without indicating itself by any symptoms except a stubborn fetid otorrhœa, resisting cure in spite of thorough cleansing of the tympanic cavity. We may be almost sure of retention of pus in the antrum, provided caries of the external canal, ossicles, or walls of the tympanic cavity may be excluded.

Inflammation of the mastoid process and fever occur only through traumatism or the retention of pus in the cells. They may subside, only to reappear. Sharp pain on pressure, united with œdema, may have existed a long time without producing any perceptible change in the periosteum and the bone surface. If the bone is greatly sclerosed and very dense, and the cortex much thickened, which conditions may be congenital or occur as a result of chronic middle-ear suppuration, such acute symptoms may never arise, even in a long course of the disease. However, the absence of the same cannot be looked upon favorably as a prognostic sign, for it is often just such cases that prove

rapidly fatal through pyæmia. Zaufal and others have called attention to the frequent existence of optic neuritis, neuro-retinitis, and choked disc in inflammation of the mastoid process, at times bilateral, at times unilateral, and not always on the affected side. The course of the morbid process in bone affection varies in different cases. Extension of the inflammation in an outward direction, with periostitis and abscess, is the most common course. Several such abscesses, in more or less rapid succession, over the mastoid process, are indicative of disease of the bone. Occasionally the pus finds its way down the side of the neck, and forms a swelling of considerable size; or it may pass forward to the side of the pharynx, and downward even as far as the pleura; or it may extend into the cranial cavity and set up trouble in the lateral sinus, or involve the Fallopian aqueduct and the membranes of the brain.

Next to opening through the cortex of the mastoid, the most frequent point is through the posterior-superior wall of the external canal. If not recognized early it may cause such excessive bulging of the canal wall as to prevent free discharge. If seen at the proper time a generous opening followed by copious syringing may suffice to empty the mastoid process of all deleterious substances, such as pus, cholesteatoma, the cheesy exudate, epidermis masses, and even sequestra if very small. Bezold has well described those uncommon cases as mentioned above. When rupture takes place toward the digastric groove, or on the median surface of the mastoid process, owing to its deep position beneath the fasciæ the pus easily finds its way into the submuscular tissues and along the course of the large vessels, and causes swelling in the side of the neck with abscess formation. In the early stages no perceptible difference may be seen between the sound and the diseased side. After the swelling beneath and on each side of the sterno-cleido-mastoid muscle has developed, deep pressure over the tip of the mastoid elicits acute pain. An early recognition of the condition is necessary, since from the consolidation of the parts invasion of the cranial cavity is likely to occur. In favorable cases the carious and necrotic portions are exfoliated, the granulation tissue is absorbed, and healing takes place. Several good recoveries have been reported, even after the whole of the mastoid process has been exfoliated. Again, only small portions of bone may be detached, and fistulous openings may remain indefinitely or until properly dealt with.

The prognosis in these cases of mastoid disease varies with the cause, extent, and severity of the affection and with the general health of the patient. Following an acute otitis media, promptly attended to, the prognosis is usually favorable, but in some such cases the advance may be so rapid as to baffle all efforts to check it. It is unfavorable in tuberculosis and in chronic purulent otitis with pent-up secretions, when the case has been neglected and has a history of intermittent febrile attacks and several previous attacks referable to the mastoid region which have disappeared spontaneously or under palliative measures. The prognosis is always serious whenever there are symptoms of extension of inflammation to the membranes of the brain. Attacks of partial or complete unconsciousness, restlessness, and feverishness are of extremely grave import when occurring in a person suffering from disease of the mastoid process.

In the treatment, if the case is seen early, an attempt should be made to abort the attack by antiphlogistic measures. If the membrana tympani appears greatly congested, swollen, and bulged outward, simultaneously with pain in the mastoid process, which is increased on pressure, a paracentesis of the membrana tympani should be made at once to permit the pus in the middle ear an opportunity of free exit; and in a spontaneous rupture, when not sufficiently large, it must be enlarged. After free drainage has been obtained, frequent antiseptic irrigations should be instituted and carried out faithfully. A brisk purge should be administered, followed by the application of cold to the mastoid by means of the ice bag, iced cloths, or, what is better, the Leiter coil. The ear may be syringed with the apparatus in place. It is better to keep the coil in position continuously for twenty-four hours, and under no condition should it be kept on longer than from forty to fifty hours. Painting with iodine, blood letting by means of leeches, and rest in bed are also to be employed. In influenza cases the Leiter coil does not appear very effectual in stopping the formation of abscesses. Cold is usually very soothing and is borne well. Often the pain will entirely disappear through these means while the patient is in bed and quiet, but on exertion in his duties the symptoms return. And hence it is said by some writers that if marked improvement has not occurred within forty-eight hours, operative treatment will be necessary subsequently, if not at once. If abortive measures have not been successful, then operative interference must be resorted to, and the following symptoms as laid down by Politzer and others are generally recognized as indicating the operation:

(1) Painful inflammatory infiltration of the covering of the mastoid process, especially if an accompanying narrowing of the meatus or obstruction of the tympanum by granulations renders it probable that a septic condition exists in the mastoid process. The operation becomes imperative when there are high fever and signs of meningeal irritation, and when the symptoms in the mastoid process have repeatedly occurred and resisted all antiphlogistic treatment.

(2) Spontaneous pain in the mastoid process, increased by pressure and accompanied by bulging of the posterior-superior wall of the meatus.

(3) Persistent or occasionally remittent pain in the mastoid process, with marked tenderness, even if there be no swelling of the external integument and no apparent obstruction to the escape of discharge from the tympanic cavity.

(4) When cholesteatoma existing in the tympanic cavity cannot be removed, or after its extraction with the malleus and incus the condition is not improved by careful irrigation.

(5) Fistulæ in the mastoid region and gravitation abscesses below them.

(6) Extensive caries and necrosis of the posterior osseous wall of the meatus.

(7) In all cases of middle-ear suppuration, during which symptoms of meningeal irritation or of incipient sinus phlebitis make their appearance.

(8) Continued septic suppuration in the attic, the symptoms remaining unchanged after removal of the malleus and incus and several months' energetic treatment, even if there are no general symptoms excepting an offensive otorrhœa.

(9) Pain in the mastoid process, developing, in certain rare cases of connective-tissue hypertrophy, in osteo-sclerosis, and in osseous scars after the healing of a mastoid operation.

The Operation.—A few hours before the operation the patient should be given a thorough bath, the parts within a radius of three or four inches of the ear should be carefully shaved, and, if the patient is a man, the beard should be removed; then the whole side of the head and neck must be energetically washed with soap and water, rinsed with sterilized water, and rubbed with ether to remove all oily substances. The ear is syringed with a solution of bichloride of mercury (1 to 1,000), and a wet dressing of the same is

applied over the entire field of operation until the patient is anæsthetized.

The antiseptic dressing is now removed, and the parts are again cleansed with bichloride and the ear is tamponed. All instruments are sterilized by boiling, and the hands and dress of the operator and assistants should receive the same careful attention as is demanded in all surgical operations. To some all these precautions may seem unnecessary, but when he begins a mastoid operation the surgeon never knows what he may be compelled to do, as through anomalous positions of the parts, or owing to extensive necrosis, the cranial cavity may be entered, either accidentally or as he may find it necessary to extend the operation to these parts.

The incision through the soft parts should be made from the tip of the mastoid and carried upward in a curved line, one-fourth inch posterior to the insertion of the auricle and to its upper attachment. It is better to make the cut, if possible, with one sweep of the knife. This is practically what is known as Wilde's incision, and its value has been greatly overestimated, as it is admissible in children only when the cortex is very thin and may be opened by firm pressure of the knife or a sharp curette; or the pus may itself find an outlet. In the adult, however, experience has taught all operators that it is not advisable to stop here, as the cortex is too dense and non-permeable. It certainly is not wise to do this and delay to ascertain what further may develop, and subject the patient to a second anæsthetization and operation when the whole work should have been completed at first. Dench states that the division of the soft parts within the meatus over the mastoid practically meets all the indications of external incision. Next elevate the periosteum, pushing the entire anterior flap forward. The bleeding vessels should be taken up with artery forceps or ligated. The parts are held back with retractors so that the posterior and superior margins of the bony canal are distinctly seen, and the whole field of operation is laid bare. The bone should be carefully examined for fistulæ or carious spots, which if found will serve as a guide for entrance into the bone. If none is found we proceed to open into the antrum, which is just behind the posterior margin of the meatus and just below its superior margin. Until entrance has been gained to the antrum the opening through the cortex should never extend above the superior wall of the meatus, and the operator should keep close to the posterior wall, thus avoiding the middle cranial fossa and a possible wounding of the lateral sinus, which may be misplaced. The cortex is best removed with a broad chisel and mallet, the chisel held parallel to the surface of the skull, and the bone cut away in thin, broad chips, the opening extending inward and forward and gradually lessening in size until the antrum is reached. This never lies less than one-half inch below the surface, although large pneumatic spaces may be found near the surface, which may lead us astray unless we are cautious. To prove it, bend a probe at the tip and pass it downward, forward, and inward for a distance of three-fourths of an inch or more, at which depth it should pass into the tympanic cavity; thus we know that the antrum has been reached and passed through.

A free entrance to the antrum having been gained, any particles of bone or cholesteatomatous masses of granulations must be removed, and the opening to the middle ear freely curetted and enlarged to give sufficient drainage. We occasionally read of cases in which, after penetration to the extreme line of safety (about five-eighths of an inch), no antrum is reached and the operation is abandoned. This need never happen. If we cut to the usual depth without finding the cavity, we should direct our canal more forward, so as to bring its apex over the meatus, when we can easily chisel into the attic. The membranous meatus may be dislodged from the posterior wall and pushed forward, or the entire cartilaginous meatus turned out, thereby making entrance to the attic quite easy. The latter method will apply to a sclerotic process. If, after the antrum is entered, no pus is found, the large cell at the apex of the mastoid must be particularly investigated, all carious and necrotic bone removed from the mastoid, and its tip excised if carious.

The operation should be continued until sound bone is encountered in every direction. If the inner plate is diseased it may be removed with almost perfect safety, as an exposure of the dura is not a grave matter under proper precaution, whereas to leave carious bone at this point is very dangerous. Exposure or even a wound of the lateral sinus, either accidentally or intentionally, is not so serious a matter as has heretofore been considered. It can be recognized by its bluish-gray color. If the vessel is opened sharp hemorrhage ensues, which if easy of access may be readily controlled by a firm compress of iodoform gauze held by an assistant, when the operation is proceeded with as if this had not happened.

The good effects of opening the mastoid antrum and cleansing the middle ear are often manifested within a few hours after the operation. The pain and temperature are both diminished, alarming symptoms subside, while the state of the middle ear rapidly improves. Subsequent to the operation, when the septic suppuration continues after weeks or months of careful treatment there probably exists a carious affection of the tympanic cavity or of the ossicula. If lumps of epidermis repeatedly appear in the irrigating fluid, it is certain that there is a cholesteatoma in the attic, which indicates an operation on the tympanic cavity; this will be described later.

The operation being completed, dressing the wound is in order. I insert into the antrum a drainage tube and pack loosely around it dry iodoform gauze, but not the external wound, merely keeping the edges separated by a strip of gauze. A tampon is placed in the meatus and the whole well covered with sterilized gauze and cotton. With a favorable course of healing it is sufficient to change the bandage every five or six days. If the temperature does not exceed 101° F. at any time during the first five or six days, or if elevated and not persistent, there will be no necessity of changing the dressing. When it is changed for the first time, the wound and canal should be irrigated with a sublimate solution (1 to 8,000 or 10,000), and the wound cavity examined carefully for remaining granulations and roughness, which if found must be scraped away.

If there are a return of pain after the operation, increased temperature, and much septic discharge, which would be indicated by a rapid soaking of the bandages and a fetid odor, a daily change of dressing is indicated. So long as the secretion is ill-smelling I use sublimate solution in the strength indicated above. After the bad smell disappears I use a one-per-cent. boric-acid solution. This must be continued until suppuration ceases. The supposition of Küster and Bergmann, that syringing out the operation cavity should be avoided, has not been sustained by the profession. So long as there is suppuration in the tympanic cavity the communication between it and the wound must be kept open for free drainage, and only when there is a certainty that suppuration has ceased may the wound be allowed to heal. Occasionally there remains, after the most careful treatment, a sinus in the mastoid process connected with an abscess cavity which requires a second operation. The duration of after-treatment varies from three or four weeks to one or two years

before suppuration ceases, and sometimes cannot be controlled no matter what is done.

It is wonderful what beneficial effect the operation often has upon the general system, which may be readily understood when we realize that the blood is kept constantly in a more or less septic condition.

Since 1891 the mastoid operation described above has been the typical one, but the collective experience in aural surgery for the last few years has shown that it proves insufficient in many cases, and so search for a more effectual process has developed several methods. In 1891 Stacke, of Erfurt, Germany, made known a new operation in chronic cases, based upon the surgical principles involved in the treatment of suppurations within rigid-walled cavities; namely, upon the complete and free laying open of the cavity, so that it can be curetted, tamponed, and treated surgically, and the operator not be compelled to satisfy himself with a more or less imperfect irrigation. The method of Stacke is practically as follows: The cutaneous incision is made a little differently than has been described, the upper part being kept closer to the auricle and carried well around to the front. The lower end must also curve more forward and extend to the tip of the process, the cut, as it were, circumscribing the auricle. The bone being bared, the membranous meatus is separated from the posterior and superior walls, and, its attachment internally being cut, is in its entirety shelled out of the osseous canal. With a small gouge or Dench's cutting forceps the most medial portion of the superior wall of the osseous meatus (lower lateral wall of the attic) is cut away, and, if present, the malleus and incus are removed. The superior wall is to be chiselled away near the drum insertion till a bent sound touching the tegmen tympani meets with no resistance on being drawn outward. The probe, as a guide, is then turned toward the antrum, and the posterior wall of the meatus chiselled away till that cavity is freely opened up. In this way Stacke converts attic, tympanum, antrum, and meatus into one large cavity. After being cleansed, the auricle is replaced and sutured; the lining membrane of the osseous canal is split and pressed as far back into the enlarged cavity as possible by the iodoform gauze. All subsequent treatment is done through the meatus.

This operation proving extremely difficult and unsatisfactory, other methods were suggested, and now what may be known as the Schwartze-Bergmann-Stacke operation has been quite generally adopted. My experience has taught me that it is the ideal one in all chronic conditions which have resisted cure after the ossicula have been removed. I now rarely perform any other, and am exceedingly happy with the results obtained. It is much quicker, easier, and safer than the Stacke operation, and is done as follows: The incision over the mastoid and the entrance to the antrum is made as in the original mastoid operation. The membranous meatus is dislodged as in the Stacke, and held well forward by a retractor. The operative field now shows the posterior-superior osseous canal, the antrum, and a bridge of bone separating them. This bridge is now removed by rongeur forceps and chisel, the section being triangular in shape, the apex at the neck of the antrum. Thus the antrum, tympanum, and meatus will be converted into one large cavity. Care must be taken at this point not to wound the facial and semicircular canals which lie directly across from this point. As a protection, if a sound is passed through the antrum into the middle ear, or, if not possible in that direction, from the middle ear as far as possible into the attic, and we confine our operating to that, we shall be within safe limits. A wound in the external semicircular canal is more unlikely to occur than one of the facial nerve.

As much of the bone should be removed as is compatible with safety, so as to make the antrum and attic as accessible as possible from the external canal. There must, however, be a ridge remaining between the meatus and antrum. In this operation I find the dental engine a most useful adjunct. The posterior membranous canal is now split outwardly to the concha as in the Stacke, and pressed back as far as possible into the enlarged cavity and held in place by tamponing.

According to Stacke, the tamponing of the membranous meatus into the artificial opening has a double advantage: (1) it secures the formation of a persistent skin-covered communication between the antrum and meatus; (2) it is a skin transplantation, from which the formation of epidermis over the entire cavity can take place. The better way, I believe, is to suture the wound over the mastoid and get primary union if possible, and do the entire treating through the meatus. If all goes well the dressings are to remain five or six days, after which daily tamponing must be most carefully followed out.

The granulations must be kept down and the cavity kept as freely accessible and of the same size as just after the operation. Even when the utmost care is taken, minute necrotic pieces of bone become surrounded by granulations, and small fistulous canals are formed leading to these dead pieces, around which the suppuration continues even after it has entirely ceased elsewhere.

The duration of the after-treatment varies in these cases also, but is, on an average, as experience has shown, several months shorter than by the old method, and the cure is much more permanent. The indications for this operation are about the same as for the ordinary mastoid.

TRAUMATIC PARALYSIS OF THE UPPER EXTREMITIES.[1]

BY JOHN E. LEHMANN, M.D.

Considered from a medico-legal standpoint, these lesions are of sufficient importance to entitle them to more elaborate consideration than can be found in the text-books of the present day. The literature is sparse, possibly on account of these conditions having arisen less frequently before the modern operating-tables came into vogue, as a large number of the traumatic paralyses classed as postoperative or anæsthetic paralyses are due to the arms of the patients being allowed to fall on the sharp or narrow edge of these tables, and as a result pressure takes place and paralysis of certain muscles or groups of muscles follows.

In a recent article entitled "Anæsthesia Paralysis,"[2] Dr. H. J. Garrigues presents histories of fourteen cases, of which five occurred in his own practice. He also quotes Kron as stating that elevation of the arm backward and outward causes the median nerve to be stretched over the head of the humerus, and, as this is a position of the arms favored by some anæsthetists, it can readily be seen to form one of the causes of these conditions.

Büdinger, also quoted in the same article, states that a frequent cause of these paralyses is pressure, occurring between the clavicle and the anterior surface of the first rib, on the brachial plexus as it emerges between the scaleni in the neck. It would appear to the author that frequently in these anæsthetic cases,

[1] Read by title before the New York State Medical Association, October 13, 1897.

[2] Journal of the American Medical Association, January, 1897.

apart from the position of the arms and forearms, trouble is caused by the anæsthetizer in one or more of the following ways: In attempting to prevent the dropping of the inferior maxilla the fingers, well abducted, are very often, particularly in beginners, placed very firmly along the neck, so as to give a strong brace for the index in supporting the angle of the jaw; by this means one or more of the fingers press upon the fifth, sixth, and seventh cervical nerves (these being the most frequently involved), near the exit between the scaleni, and, as frequently is the case, the head is rotated to one side and the nerve or nerves are compressed between the fingers and the vertebræ. Again, as has often been observed by the writer, the anæsthetist will be found leaning or bearing his weight upon the patient's arm or forearm, especially so when the patient's arms are drawn above the head, thus causing pressure of the nerves to take place between the humerus of the patient and the anæsthetist's arm or between the humerus and the operating-table. Again, some of the assistants, in their overassiduous endeavors to hold a patient down during the stage of excitement, produce the trauma either by firmly encircling the arm with the hand and thus compressing the nerves, or by holding the arm down against the sharp or narrow edges of the table. The author has on several occasions seen one of these assistants throw his entire weight upon the upper extremity and chest, using the trunk of his body to hold down one arm, and by reaching across the patient's chest hold down the arm of the opposite side with his hands.

Recently a case of this class, *i.e.*, of postoperative paralysis, was referred to me with the following history:

Case I.—Male, aged about thirty-six, bartender by occupation, had his forearm cut by the explosion of a siphon of seltzer on June 10, 1897. The injury was at the junction of the lower and middle thirds of his forearm, and cut the flexors of his little, ring, and middle fingers, possibly also that of the flexor carpi ulnaris. No attempt was made to unite the severed tendons, and the injury was healed in three weeks. The only impairment of function was in the fingers mentioned. The thumb and index finger were uninjured, as the patient stated that he used them constantly.

On July 19th he was operated upon with a view to uniting the severed tendons. An incision eight inches in length was made on the ulnar border of the forearm, and as far as can be judged at the present time with perfect success as far as union of the divided tendon is concerned.

September 5th, he was referred to me, and examination revealed a complete paralysis of all the muscles of the forearm. The only motion of the forearm retained was feeble supination, and that was demonstrated as being due to the action of the biceps.

The operator in the case was an able and careful surgeon, and the incision certainly could not have implicated any but the ulnar nerve. That this lesion could not have been an ascending neuritis entirely, is evident from the fact that the function of the thumb and index and of all extensors was perfect previous to the operation; and that these functions were abolished shortly after the operation points to a pressure trauma of operative origin, possibly to the use of an Esmarch bandage for a bloodless operation, in addition to the table pressure by reason of the extension of the forearm and arm.

In addition to the postoperative or so-called anæsthetic paralyses, it happens frequently enough that the surgeon sees cases of paralysis following dislocations of the shoulder, especially when not reduced for some time; cases of fracture of the humerus, in which the musculo-spiral is involved in the callus or in fibrous tissue, or by stretching of the nerve over an angular deformity; contusions of the shoulder followed by deltoid paralysis due to the involvement of the circumflex, etc.; paralyses due to pressure in the axilla caused by the use of crutches or by tumors, etc.; paralysis caused by sleeping with the head resting upon the arm or forearm; and, as in one case recently seen by the author, implication of the ulnar nerve in a marksman who used his elbow as a rest while shooting in the prone position at the Creedmoor rifle range.

Case II.—Complete paralysis of the upper extremity following unreduced dislocated shoulder of three weeks' standing. D. S——, about twenty-two years of age, sustained an injury to his left shoulder while bicycling at Liberty, N. Y. A diagnosis of dislocation of the shoulder was made and the ordinary treatment applied. Twenty-one days after the injury he was referred to me, and upon examination a subcoracoid displacement was found to exist, which apparently was rather firmly retained by adhesions. He complained of inability to use the arm, considerable pain in his elbow, and tingling with numbness of the fingers, particularly those supplied by the ulnar nerve. A complicating pressure neuritis was diagnosticated, and the possibilities of paralysis were told the patient. As will be seen, this was a wise precaution.

After the patient was anæsthetized in my office, the shoulder was reduced with some difficulty. Within ten days after the reduction there was a total paralysis of the entire arm and forearm, with rapid atrophy particularly marked in the muscles of the hand. Electrical reaction was retained both to the faradic and galvanic currents, but was finally lost. The return of reaction to the galvanic current was manifested about twenty-one days after its loss and within six weeks the return of contraction with the faradic was observed. The patient left my care about eight months after the injury was received, with an arm and forearm considerably smaller than those of the opposite side, but with restored function in all of the muscles.

Case III.—Complete upper-arm paralysis from contusion. Mr. R——, track inspector, was struck by the Empire Express and was thrown about twenty feet. He was referred to me two days later by Drs. Piatti and Thompson, of Greenwich, Conn. Upon examination he was found to have sustained a compound fracture of each of the bones of the right forearm near the wrist, and a simple one of the ulna at its middle. Drs. Piatti and Thompson had made an excellent skiagraph, which showed the latter fracture very distinctly. In addition, the entire right shoulder and right half of his thorax were ecchymosed. The fractures were treated as usual in these cases, and complete repair was observed in the sixth week. It was noted at this time that the deltoid, which formerly was exceptionally well developed, had atrophied to a very small and useless mass of tissue, allowing the shoulder to drop so that it was mistaken for a dislocation. He was again referred to me, and in addition to the deltoid atrophy we found a complete paresis of the entire upper arm. A cure was obtained in about six months in this case.

Case IV.—Musculo-spiral paralysis following a fracture of the humerus. W. K——, aged thirty-nine, driver, while attempting to check a runaway on September 2, 1896, was knocked down and sustained a fracture of his left humerus about the junction of the lower and middle thirds. He came under my care on November 23d, with a history of paralysis of his lower-arm muscles, etc.

Upon examination it was found that the fragments had united without the formation of any excess callus, but with a slight angular deformity, the lower fragment being forward. In examining the functions of the wrist and fingers it was noted that extension was abol-

ished, with the exception of extension of the distal and mid phalanges of the index, middle, ring, and little fingers. This naturally was ascribed to the action of the lumbricales and interossei. Supination was lost, except to a slight degree obtained by the action of the biceps. He complained of tingling in the region of the radial-nerve supply, numbness of the fingers, and some pain in the course of the nerve.

Operation was advised to release the musculo-spiral, and accepted. November 24th, with the patient under ether, the musculo-spiral was cut down upon, and instead of being found in a bed of callus it was found to be compressed by a dense band of fibrous tissue binding it over the angle formed by the vicious union. The angle of vicious union being so slight, refracture was deemed inadvisable, and chiselling away the point of bony pressure was resorted to. This patient was discharged with good function in the previously paralyzed muscles about six weeks after the operation.

Diagnosis, as a rule, is an easy matter. The history of an injury with a following loss of power and atrophy in one or more muscles or a part of the extremity, with tingling, numbness, shooting pains, sometimes loss of sensation in certain areas, and frequently œdema or swelling of the extremity or fingers —all point to traumatic paralysis.

Prognosis usually is good, but it may require eight or twelve months for a return of proper functions, while the return of power as it existed before injury may take from one to two years. If the patient is placed at work as soon as voluntary muscle contractions return it will assist very materially in bringing about a rapid recovery. The mere fact of loss of reaction to galvanism after loss to faradism need not provoke an unfavorable prognosis, as this condition usually abates within a few weeks.

Treatment resolves itself into the use of strychnine and potassium iodide internally; massage from one séance weekly to a séance daily; the use of the faradic and galvanic currents, as indicated by the return of reaction of degeneration; and a support to the extremity, particularly to overcome the possibility of stretching that will take place in one set of muscles (the paralyzed ones) at the expense of the other, as by the use of a palmar splint to prevent wristdrop, etc. The use of a splint will also be found to aid materially in the return of power in the paralyzed muscles. The use of artificial muscles cannot be too strongly commended; in two of the reported cases the writer had ordinary dress hooks sewed upon a leather glove of the Dent or Fowne variety, a hook sewed upon each of the fingers of the glove corresponding to the paralyzed fingers, and a set of hooks above the wrist in direct line of traction of the tendons; then ordinary elastic bands were hooked on, until a slight degree of overtension was obtained. This glove was worn in the daytime, and at night the splint was applied.

149 West Forty-Fourth Street.

Gastro-Intestinal and Hepatic Relations of Gout. —1. Gout is a definite disease to which certain individuals are predisposed, but which depends for its development upon causes largely unknown. 2. Laziness and full nitrogenous diet and the use of fermented liquors predispose to the disease. 3. So-called lithæmia, as the term is popularly applied, is not gout, but is an auto-intoxication depending upon gastro-intestinal and hepatic derangements. 4. The diet in gout should be largely free from nitrogenous substances. 5. The diet in lithæmia must be ascertained by a careful study of the primary digestion, the urine, and the general health of the patient, but a nitrogenous diet is often the most satisfactory one.—Charles G. Stockton.

ALCOHOLISM IN WOMEN — ITS CAUSE, CONSEQUENCE, AND CURE.[1]

By AGNES SPARKS, M.D.,
Brooklyn, N. Y.

Alcoholism in women has heredity as a genetic factor to a lesser degree than in men. Departures from ancestral health find their entailment in the gentler sex more often along the line of other and less complex neuroses.

Alcoholism in women presents somatic factors in causation in larger measures than in men. The mistaken ethics of a social code that impels to accept, all too often, the proffered poison, and so tend steadily down to a disturbed physique that involves structural impairment and a badly crippled *morale*, does not obtain so largely among them.

Apart from the frequency with which alcohol is used to spur flagging energy, to obtund distressful feeling, or bring oblivion from cark and care, probably the genetic condition most often met with is one involving painful performance of her special function. The average woman finds this a time of discomfort more or less pronounced, to relieve which rum in some form is used—a heritage of tradition both in precept and practice unsafe—with a result, just as in the pernicious plan of giving opiates at these periods, of inducing a recurring condition of rise and fall as regards well being until the interim is fully bridged, and a state of more or less steady inebriety ensues.

The most potent cause is twofold. First in frequency is a neurasthenic condition due to lack of nutrition and the wear and worry of domestic life and social demands—an exhaustion for which relief is mistakenly sought in the transient aid of alcohol, all unaware or unmindful of the vital fact that its taking involves large risk of creating a morbid condition that often finds expression in inebriety.

The other factor is the pain and unrest incident to disorders of their sex, for which solace is found in the anæsthetic and paralyzing effects of alcohol—an effect that with startling and sorrowful frequency ends in this toxic disease.

Inebriety from a fondness for alcohol *per se*—vicious indulgence—obtains less often in women. Why this is so goes without saying, and so this neurosis in them presents the strongest possible proof that its origin lies in perturbed physical conditions; in fine, that it is a disease: no mere moral obliquity, as many—well meaning, but mistaken—would have us believe.

The consequence of alcoholism in women is less promptly patent than in men. Albeit none the less sure, it obtains more slowly. This from varied causes that act over larger area and with greater energy in men. In the earlier stages of inebriety in those cases in which volition is not entirely ended, a peculiar shrinking from publicity protects some women against the objective symptoms noted among men at a like period of their disease; but with increase of toxic power due to constant or recurrent taking this protective shield gives way, and a well-marked consensus of symptoms, psychical and somatic, lays bare the varied ravages of the disease. Among them the latter lead, and early and often those along gastric lines. To detail is not needed; but—so well masked may be the true status —in every case of marked disorder in this regard, if not yielding to the usual remedies, the doctor should make bold to question the patient, direct, as to rum being a factor for ill.

With progress of the toxic force widespread disturbance of functions presents—scarcely any escape—and as the disorder deepens into structural change the

[1] Read before the New York Medico-Legal Society, October 20, 1897.

signs of health infraction become more pronounced and prolonged.

On ovulation the alcoholic impress is one of deranged rather than, as in opium inebriety, suspended action, and so it comes to pass unfortunately that the average female alcoholist is not sterile. Just the reverse obtains with the woman morphinist, and it is one of the mysteries of a divine economy that this beneficent law does not extend the same wholesome result in her alcoholic sister, and so shut off in large measure a diseased, depraved progeny that tends to curse every community with a physical and moral blight, the extent of which is beyond compute, and with which no other agent for ill can compare.

Sequelling visceral disturbance comes psychical derangement, ranging from slightly erratic outbreaks to furious maniacal outbursts, or a more or less steadily stupid condition. The latter is less frequent than in men, the inebriety of women more often being periodic. While the signs of psychical ill-health may be less gross than in men, they just as surely show the fell power of this poison to distort and destroy along higher lines of life, and transform many a winsome woman into one far removed from her gentle self and deserving the largest measure of sympathy and relief.

The prognosis of alcoholism in women eligible for treatment is better than in men. Barring advanced cases, the outlook for recovery is hopeful to an extent that warrants placing every patient under proper care. The betterment gained by well-directed treatment in some cases is surprising, and were this fact well known, would, it is safe to say, lead to a larger optimism among medical men as to cure. Risk that the disease will recur is large. This, however, by persistent treatment, favoring environment, and watchful care, may be brought largely to a minimum, and many a life seemingly given over to a rum bondage till death can be reclaimed.

The treatment of alcoholism in women, to be most effective, must be twofold—curative and preventive. Touching the former, modern medicine has made such advance as places present treatment much in the van of everything that has been. As a valued psychical adjunct, the doctor must be firmly impressed with a belief in his power to help, and the impress of this opinion must be made on the patient to the full if the maximum of good would be gained. A supreme confidence along this line is an immense factor in reaching the goal desired, and so far as concerns non-coercive care is almost a *sine qua non*.

The remedial agents of greatest worth in warring on this disease are strychnine, arsenic, electricity, and hypnotism. But before any of them can be made of most service certain untoward conditions claim attention. The gastro-alvine status must be righted, and nothing will better do this than a mild nightly mercurial and a morning aperient water. Uterine luxations should be reduced, ovarian discomfort must be ended, and, unless removal be called for, galvanism holds out the largest promise for good.

The question of abrupt or gradual rum quitting will present. Case conditions must decide. If possible, the former should obtain. As a rule, fear of ill result is unfounded, and the effect on the patient's *morale* will be good. If sudden stopping be deemed unwise, let the usual stimulant be discarded, and alcohol in like amount be given with milk, to be ended as soon as possible; or, better still, the compound tincture of cinchona combined with nux vomica and tincture of gentian, or the mineral acids.

The way for the main treatment having been paved, strychnine leads the list. There have been such a consensus of opinion and such a volume of fact to this effect as cannot be gainsaid or set aside. It is best given subcutaneously, in the form of nitrate, one-thirtieth to one-twentieth of a grain thrice daily. As a rule, it will be best not to exceed the latter dose, and if strychninism presents a decrease is in order. The average alcoholic is very tolerant of this drug; this fact should not be forgotten. These full doses may be given a month, if well borne; after that, one-sixtieth to one-fortieth of a grain will suffice, and with or without arsenic should be given for months.

Arsenic in inebriety is not given the credit it deserves. It is a *multum-in-parvo* remedy—a general tonic, a non-neuralgic, an antimalarial, a nutrition promoter; in fine, an all-round roborant, admirably adapted to the cure of this disease. Fowler's solution is best—four to eight drops after each meal. It may sequel the strychnine giving, and not be pushed beyond slight face puffing. It should be long continued—in this is its chief value—four to twelve months.

Electricity is another remedy, the worth of which in the treatment of inebriety is much more than the average doctor will admit. Ignorance of its value comes from inexperience. Study and practice of this valued aid must be had if one would be well equipped. There are few facts in medicine better fixed than the power of galvanism to raise the lowered nerve tone and relieve the varied neuralgias so common to this disease. Constant-current séances, ten to twenty minutes each, may be given daily for weeks, and a specially opportune time, when sleep is impaired, is at night. When used for neuralgia, each of the attacks, be they frequent or few, must be met promptly. The faradic current, while less widely useful than the constant, may be given daily, twenty-minute séances, general faradization, as a tonic and to remove the peculiar unrest—"fidgets"—noted in some cases.

Hypnotism acts best in periodic cases. Séances should be had between drinking-bouts. No case should be deemed unyielding till several attempts have proved futile. It is very effective in some temperaments. The condition of each case must govern as to time and extent of séances. To a minor degree most women can be brought under hypnotic influence if, as we have urged, the physician be largely optimistic as to treatment and will stamp the impress of that optimism on the patient. In every case effort to this end should be made. Despite adverse opinion, hypnotism is sometimes an immense power for good.

We have noted the biggest guns in the battle with this disease. Minor ones are of value. Full feeding ranks first; generous diet, with cod-liver oil and malt if need be, must be given. If patients be pallid or heart action weak, steel and strophanthus should be used. The Turkish bath fills an important rôle as sedative, eliminant, and soporific. A morning cold shower is a capital tonic. If a hypnotic be needed, trional outranks all others; dose, fifteen to thirty grains, dry on the tongue, at 7 P.M., or in hot milk or bouillon at bedtime.

The pain peculiar to chronic alcoholism can often be eased by cannabis and quinine. If not, coal-tar products may succeed. All failing, an opiate can be given, but it must not be morphine; that is unsafe; it is snareful, chronic alcoholics take to it too kindly. Codeine may be given. This drug—for the greatly increased use of which in America during the last six years the profession is mainly indebted to Dr. J. B. Mattison—one-half to two grains of the phosphate or sulphate by skin or mouth, is an efficient anodyne, and the risk of tolerance is vastly less than with morphine.

One remedy, radical and a *dernier ressort*, remains to be noted. Granting the woman has been given treatment, proper, persistent, and prolonged, without avail, she should be asexualized. This, whether maid or matron—for many a former would not have the courage of conviction equal to that of a young woman brought to my notice, who refused an alluring

offer of marriage solely because she was a periodic alcoholic. It might be curative, it surely would be preventive; and better by far unsex the woman than have her beget a brood tainted with this curse of the world.

Special stress must be laid on the need for treatment long continued. Lack of this is the largest factor in failure. It is absurd to suppose that a system, bruised and battered by alcoholic excess for years, can be brought back to health in a few weeks or months. The good work must go on, if need be, for years. True, much may be done in some cases by less-protracted care, but as a rule the risk of recurrence makes the longer treatment of greatest worth. The skilful doctor repairs or retards the ravages of renal or cardiac disease by care years continued, and the same wise effort along alcoholic lines must obtain if the largest measure of good would be gained. There is great incentive to such effort. Even now, from thirty to fifty per cent. of alcoholic inebriates properly treated recover, and, with a clearer insight of causative conditions and a more extended remedial *régime*, there is full warrant to think this good result will be greater.

No case should be deemed beyond hope till every aid that scientific treatment can now surely extend, under either willing or coercive care, and continued if need be for years, shall prove of no avail.

So much as a present spur. When we face the future, and realize the fact that in the new century, so near, the question of the effects of alcoholism on the physical weal of humankind will be the question outranking all others, phthisis not excepted, to engage attention of scientist and sanitarian; when we give due thought to the fact that alcoholism is not only a curable but a preventable disease—we must be profoundly impressed by the immensity of its importance; and let our every effort array against it, for it compasses not only the welfare of a present host, but that of millions yet to be.

Clinical Department.

HEMORRHAGE INTO THE PERICARDIUM.

By U. S. BIRD, M.D.,
Tampa, Fla.

On July 20, 1897, during a cutting-affray, a healthy, middle-aged negro man received several wounds, which were properly treated. July 24th I was called to see him. The only serious wound was a stab in the left side, in the axillary line, at the level of the seventh and eighth ribs. This wound was horizontal, about one inch long, extending upward and inward for some two and one-half inches. From it, especially when he coughed, came a large quantity of bloody serum. There was some whistling through the lips of the wound during respiratory movements, but this ceased after a few days. His respiration was labored and rapid, preventing him from sleeping. Morphine partially relieved this symptom. As there appeared to be an accumulation of liquid in the chest, I used a large aspirating needle in the first interspace below the wound, but found nothing. By July 29th the discharge had lessened in quantity, but had become purulent. On August 2d I made an opening a little lower than the original wound, and packed lightly with gauze. By August 4th the discharge seemed enough only to dampen the gauze. On this day his condition was good. His breathing, which had been rapid and distressed, was 24 and easy. His pulse was 120, but improved. His appetite was good, and his bowels and bladder acted well. His feet became swollen a few days after I first saw him, and continued in that condition. Wednesday morning I saw him last. When I called August 5th, his nurse told me that he had coughed a little about daylight. After being raised to a sitting position he coughed up a little blood and immediately collapsed. She thought that by the time she laid him down he was dead.

About 2 P.M. I made an autopsy. When the sternum with the costal cartilages attached was removed, the pericardium was seen to be distended and of a bluish tint. This was opened and some ounces of black clot removed. The heart was compressed and empty. There were firm and extensive adhesions between its left surface and the pericardium, and between this part of the pericardium and the pleura. The heart was not wounded, but the pericardium had here sustained an extensive incised wound, similar to the external injury. There was a ragged wound in the lower edge of the left lung, which was also consolidated and adherent. There were no accumulation of liquid, and no apparent communication with the external wounds. His death was probably due to compression of the heart by the hemorrhage into the pericardium, which was probably due to the rupture of a weakened pulmonary vessel, caused by the exertion of coughing. In a sense, death was accidental. The loss of that quantity of blood was not likely to have caused death. A few days longer might have been sufficient for the formation of adhesions which would have made such a result improbable.

HYSTERICAL APHONIA.

By A. C. FOLLETT, M.D.,
Schenevus, N. Y.

In a recent issue of the Medical Record is an article by Dr. Sanger Brown, of Chicago, upon a cure of this affection by suggestion. I had my first and only case of this sort about two years ago, and I cured the patient (at least she recovered) in four days by means of suggestion. She had been aphonic for several months. I really brought her voice in one night. I told her to do this, that, and the other for three days—none of the things prescribed being more than a placebo. I gave minute directions to be accurately followed, and emphatically directed her to speak upon the fourth morning, which she did and not before. I previously had examined her vocal apparatus with the laryngoscope and had found nothing pathological.

A CASE OF PUERPERAL SEPTICÆMIA SUCCESSFULLY TREATED BY ANTISTREPTOCOCCUS SERUM.[1]

By H. SIFF, M.D.,
New York.

The object of this paper is not to try your patience with scientific speculations, numerous quotations, or new discoveries; I desire to report to you a case based on solid facts and supported by the opinion of some very eminent authorities, and if my views prove to be correct, and you, after weighing the cons and pros of the case should finally coincide with me, then the medical world may congratulate itself upon its success in dealing with and destroying the dreaded micro-organisms which are constantly at work undermining our vitality. The case I refer to is one of puerperal septicæmia successfully treated by antistreptococcus serum.

On the morning of March 19th I was invited to see Mrs. M——, on Grand Street. The nurse gave me the following brief history of the case: Mrs. M——, a primipara, after labor pains which lasted only about three hours, was delivered six days ago of a healthy little female child, weighing about nine pounds. The

[1] Read before the Eastern Medical Society, April 9, 1897.

midwife had no trouble with the placenta, and mother and child were in perfect health. This occurred on Friday evening, March 12th. During the following Sunday and Monday the parturient complained of headache, and Monday evening she had a prolonged chill.

On Tuesday a physician was called in. Cathartics and antipyretics were prescribed, but the patient grew worse. The temperature ranged between 105° and 106 F. During the following two days a similar line of treatment was followed, some intra-uterine antiseptic douches were given, and the physician in attendance wanted to curette, but the family objected. On Thursday vomiting set in, which resisted all treatment, and the temperature continued to range between 104.5° and 106° F.

On examination I found the uterus pretty firmly contracted and the os closed, although not completely, but sufficiently to exclude the probability of any retained secundines. There was no lochial discharge, no offensive odor, no excessive tenderness anywhere. Only a few small areas of slight tenderness over the fundus of the uterus could be mapped out. The temperature was 105.8° F.; the pulse thready and hardly perceptible; the heart's action feeble, accelerated, and beating 130 times per minute. The entire body was covered with a cold and clammy perspiration, a peculiar sweetish odor emanating from it. The face was flushed (showing several ecchymotic spots), the teeth and gums were covered with sordes, the tongue was brown, and the extremities were cold.

The mental condition of the patient was the one characteristic of septicæmia—slight delirium, general apathy, and indifference, always begging not to be disturbed, to be allowed to die, etc. The expression of the eyes was dull and lifeless. The two most distressing symptoms were persistent vomiting and insomnia, the patient not having slept for nearly seventy hours.

As the attending physician refused to treat the case for not being permitted to curette, I at his request took charge of it. I prescribed large doses of musk, nux vomica, strophanthus, and digitalis to prevent collapse, and ordered three ten-grain doses of sulphonal with some cocaine and sparteine to produce sleep and check the vomiting.

I pronounced the case septicæmia, but advised against curetting, as I was positive that there was nothing in the uterus to justify any such interference. Although I was confident of my diagnosis, I invited Dr. A. Jacobi in to the case. After a careful examination he expressed himself satisfied with the diagnosis of puerperal septicæmia, and advised intra-uterine injections of a solution of permanganate of potassium, 1 to 3,000.

On the next morning vomiting had ceased, the patient had slept a few hours, but the temperature was again 106° F., and the condition of the heart was so alarming that I had to give heroic doses of powerful stimulants, like musk, etc. I wanted to try some antitoxin, but I met with objection on the part of the family, as they had had some bad experience with diphtheria antitoxin. Dr. P. F. Mundé, who by invitation saw the case with me on that day, agreed with me on every point, and as there was nothing to lose, a fatal prognosis having been given, he also advised trying antitoxin. I procured antistreptococcus serum and injected into the hip ten cubic centimetres. This took place at 9 P.M., the patient's temperature then being 104.5° F. During the night the patient had diarrhœa in consequence of a powder of ten grains each of calomel and jalap, which I administered on the preceding evening. The diarrhœa was violent, about twelve or fifteen movements within eight hours; the patient became exhausted and seemed to be rapidly sinking. I hurriedly prescribed some opium, bismuth, and salol, and succeeded in checking the diarrhœa.

At 9 A.M., twelve hours after the injection of the serum, the rectal temperature for the first time since the onset of the disease was only 103° F., instead of the regular 106° of the preceding four days. The delirium had ceased and the patient was easier. I again injected ten cubic centimetres of the serum. This time the injection seemed to cause some pain, as the patient made quite an outcry, while during the first inoculation she seemed to be entirely indifferent to the pain of the needle.

Twelve hours later the thermometer registered 102.5° F. The appearance of the patient had changed. There was no longer that gaze of apathy and indifference, and the ecchymotic spots on the face had almost vanished. The tongue was no longer brown; it was still coated, but white, and the sordes on the gums and teeth were half gone. The senses of the patient, however, were at short intervals blunted, and she would, while speaking rationally, all of a sudden interpose an incoherent sentence. I examined the urine, and as the result was negative (thus satisfying me that the serum was assimilated, as otherwise the kidneys would have excreted some albumin) I again injected ten cubic centimetres of the antitoxin. This time I met with violent resistance on the part of the patient; she was sensitive to pain and was fully conscious of what was going on.

The next morning, thirty-six hours after the first injection, the temperature was 102° F. and the lochial discharge reappeared. At noon the thermometer registered 100.5° F., and in the evening 99.5° F. The temperature afterward never rose higher than 102° F. But then new trouble began—the heart's action became very irregular and alarmingly intermittent, especially so whenever the temperature was below 101° F.; it would then very frequently leave out two beats successively. After three days of stimulation by large doses of musk, cardiac action became normal and the patient completely recovered.

The question now arose in my mind: Was this recovery the work of the antitoxin, or was it merely a coincidence? Perhaps the septic poison was eliminated by the diarrhœa. Dr. Mundé, whose opinion should certainly command respect, ascribes this recovery to the antitoxin. Discussing this subject in a letter I received from him, he says: "I do not believe that the purgative did it. I am glad there seems to be at last an antidote for septic poison." I myself, conservative as I would like to appear, am convinced of the correctness of this opinion, not so much by the recovery itself as by the rapidity of its occurrence. To see a temperature of 106° F. fall to 99.5° F. in forty-eight hours is not usual with septicæmia of this type. I must admit that a rapid recovery may take place in some cases of puerperal septicæmia, but it should be borne in mind that only in such cases of septicæmia can this occur in which the cause is early discovered and promptly removed—as, for instance, in case of retained secundines.

As to the possibility of the septic poison having been eliminated by the diarrhœa, I do not think this can encroach upon the credit which I wish to claim for the antitoxin, for we all know that excretion is the rule in septicæmia; cold sweats and offensive diarrhœa are generally the agents which usher in the fatal issue, and cases of septicæmia which do terminate in recovery are mostly such as were not aggravated by diarrhœa.

Now some conservative minds may ask: Is septicæmia always fatal? To this I would reply that, while there may occasionally be recorded a case of recovery from puerperal septicæmia when the cause was not discovered and certainly not removed, I do not think

recovery probable in a case of such grave character accompanied by all of the distressing symptoms which I fully described above. Then, again, I would refer the sceptic to the rapidity of the recovery—forty-eight hours! That certainly is not usual.

While I am fully aware of the fact that it requires more than one test to convince a physician of the efficacy of a certain therapeutic agent or mode of treatment, I trust that the case described by me will give the obstetrician sufficient inducement to test this serum treatment. There is no reason why the streptococcus should enjoy more protection than the Klebs-Loeffler bacillus. There was a time not long ago when men high in the profession who are now ardent advocates of diphtheria antitoxin were relentlessly denouncing it as useless, dangerous, etc. They were quite sincere in that denunciation, which they claimed to base on the result of numerous statistics, until they finally were conquered by other numbers. Maybe we can now declare war on the streptococcus.

The fact that there are other pathogenic microorganisms present in the blood of a septicæmic patient should not deter us from attempting to destroy the one which is always present, even if this could result only in slightly lessening the virulence of the septic poison.

[illegible]

BILATERAL SUBLUXATION OF THE CRYSTALLINE LENSES WITH ECTOPIA OF THE PUPIL OF THE LEFT EYE.

By G. N. BRAZEAU, M.D.,

[illegible]

About two weeks ago a man came to consult me about his eyes, complaining of the great diminution in his acuteness of vision. The patient is thirty-four years old, healthy, and has a good family history. I found upon inspection a tremulous condition of both irides with ectopia of the pupil of the left eye. The pupil was at the sclero-corneal junction.

Ophthalmoscopic examination of the right eye, for it was impossible in the left, revealed a lateral subluxation of the lens toward the outside. The border of the lens was perceptible only on dilating the pupil. The margin of the lens appeared as a heavy dark curve, since the rays coming from the fundus of the eye to the margin of the lens were deflected from their course by virtue of the difference in the refractive media. There were a large staphyloma, however, not encroaching upon the region of the macula, and a small papilla, two conditions peculiar to myopic eyes. The patient was highly myopic, and despite the peculiar condition of the pupil in the left eye he could see with that eye sufficiently to find his way.

The tremulous condition of the irides suggested immediately to my mind the probability of an abnormal position of the lenses, which true enough was very manifest on ophthalmoscopic examination, and which I afterward verified by instilling atropine and securing that visual condition so peculiar to displacements of the lenses referred to above.

It was impossible to elicit from the patient or his friends positive information concerning the date of the origin of the tremulousness of the iris; however, the fact that he attended school until the age of eighteen, though myopic, and his chief complaint dated from September, 1869, lead me to believe in an acquired dislocation rather than congenital one.

On the other hand ectopia of the lens usually accompanies ectopia of the pupil, which is itself a congenital condition. From that fact together with the tremulousness of the iris, I believed in a displacement of the lens, although I was not able to see it as in the other eye. There exists with this ectopia of the lens either marked hypermetropia, myopia, or astigmatism; in this case it was myopia and astigmatism. The myopia in the right eye was partly overcome by the removal of the lens. The true anatomical cause for dislocation of the lenses lies in the alterations in the zonule of Zinn, which consist in either elongation, relaxation, or degeneration of its fibres. Both the lens and iris, being deprived of proper support, naturally must tremble. Any displacement of the lens gives rise to changes in the vision, particularly if it occupies a portion of the pupillary space. The part containing the lens becomes myopic on account of the extreme convexity of the lens permitted by the relaxed zonule, and the other hypermetropic from absence of the lens.

Astigmatism is also very marked, because the light is refracted unequally in the different meridians of the lens, a condition called regular astigmatism. Diplopia is also explained by the fact that the margin of the lens acts as a prism whose apex corresponds to the equator of the lens. Diplopia also results and neither of the two images is distinct, for one is seen by a hypermetropic eye and the other by a myopic one—the former corresponding to that part of the pupil deprived of the lens, and the latter to that containing the greatly convexed lens. In time nearly all subluxated lenses became luxated and opaque. Iridocyclitis is apt to result from the constant jerkings of the lens and iris in this latter condition.

The treatment consists in remedying by glasses properly fitted—a plus glass for the side deprived of a lens, or a minus for the side with it, besides proper correction of the astigmatism. Uveal complications require their special treatment.

A CASE OF STRANGULATED APPENDICAL HERNIA.

By F. D. VANDERHOOF, M.D.,

[illegible]

On August 5th, I was called to see Mrs. G——, aged fifty-seven years, whose general health was good, but who was inclined to be somewhat stout. She presented the general or usual symptoms of strangulated hernia, such as tumor in the groin, tenderness of the lower part of the abdomen, pain, nausea, etc. Gentle taxis was used with no success, and I then administered by hypodermic injection one-quarter grain of morphine sulphate into the tumor. After waiting an hour, I again tried taxis but with no better result, and, concluding an operation was necessary, called Prof. D. M. Totman, of Syracuse, in consultation. The patient was etherized and gentle taxis was again tried, but we could not reduce the mass. Dr. Totman cut down upon the tumor and readily found the sac, which contained about a half-ounce of fluid, but none of the usual contents of herniæ. Upon careful examination, to our great surprise, we discovered only the appendix forming the contents of the sac. The latter was firmly adherent to the femoral ring, and markedly injected but not otherwise diseased. The appendix was slightly congested and adherent to the sac at the ring; otherwise it was in normal condition. After we had broken up the adhesions and dilated the ring, it was decided to return the appendix to the abdominal cavity. The sac was then sutured to the ring and the wound was closed. The patient made a rapid and uneventful recovery, and now nearly two months after the operation is in the enjoyment of perfect health. It was questioned at the time what it was best to do with the appendix, amputate or return; in the light of subsequent events we are of the opinion that the wiser course was followed.

A PECULIAR CASE OF APPENDICITIS

By H. S. JEWETT, M.D.

H. Z——, German, aged thirty-seven, grocer, married, six feet in his stockings, weighing two hundred and thirty pounds, had till his final illness never lost a day's time from sickness since childhood. Having been slightly constipated for several days, he took a dose of castor oil on retiring, March 1, 1897. The oil procured for him four free (but not watery) stools between 8 A.M. and noon of March 2d. The 2d of March being his birthday, the evening was celebrated by a lunch, with beer, with his friends. To this lunch he ascribed all his sickness. After going to bed he was restless and could not sleep. He had slight pains, which started in the back, in the region of the kidneys, and passed downward to the scrotum, with desire to pass urine, and also to defecate. This feeling caused him to make frequent trips to the water-closet, though he had no stool, and passed but little urine each time.

On the morning of March 3d he took a large tablespoonful of castor oil, which had not acted on his bowels when I saw him at 4 P.M., March 3d.

At that time I obtained the above history. He was then restless, alternately lying down, getting up, and walking about the room. Temperature, 98.8° F.; pulse, 80, full and even; abdomen soft (absolutely no rigidity of either side; no tenderness on pressure (even when deeply made); no nausea. I prescribed five grains of salol every three hours, and ordered enemata of warm soapsuds to aid the oil already taken.

March 4th, 8 A.M., the patient had passed a bad night; he was very restless, with constant desire to urinate and defecate, though the bowels had not yet moved. Temperature, 99° F.; pulse, 84, full and regular. No nausea, no tympanites, no rigidity of abdomen, no tenderness on pressure, nothing abnormal to be felt per rectum. The tongue was dry and slightly coated with brown fur. There was continuous thirst and a constant desire to defecate and urinate. I ordered five grains of calomel, to be followed by Epsom salts in five hours (if the calomel had not acted by that time).

March 4th, 7 P.M., temperature, 99° F.; pulse, 84, regular and of good strength. The first dose of salts was vomited as soon as taken; a second dose (taken one hour later) was retained. The bowels had moved once, but the desire to go to stool was not relieved. The man was very restless, moving about the room and trying to defecate or pass urine every few minutes. I passed a catheter and drew off three ounces of urine of a dark amber color; specific gravity, 1.024; no albumin or sugar; indican above normal. I prescribed morphine, one eighth grain, every three hours.

March 5th, 8 A.M., Dr. J. C. Reeve, Sr., saw the patient in consultation. The patient had passed a very restless night—up every few minutes to pass urine or to try to have a stool. Temperature, 99° F.; pulse barely perceptible and very rapid. No pain, no tympanites, no tenderness over abdomen, no rigidity of abdominal walls. Nothing to complain of but moderate, constant tenesmus of bladder and rectum. He collapsed while on the night stool (trying to defecate) at half-past nine, and died at 11:45 A.M., March 5th.

Autopsy, 3 P.M., March 5th: The abdominal walls were very fat (two and one-half inches thick). The greater omentum descended to the pelvis, and was loaded with fat (being one and one-half inches thick). The usual incision through the linea alba was made, and pus oozed out of the lower angle of the wound as soon as the peritoneum was opened. With the exception of the presence of pus, everything was normal save in the region of the cæcum. Here the intestines were glued together by lymph, forming a pocket which contained about one-half pint of pus and the gangrenous appendix, which had sloughed entirely off at one-fourth inch from the cæcum. The appendix pointed upward and to the left, and was adherent to the mesentery of the ileum. The portion which had sloughed off was four inches long and five-eighths inch in diameter. It contained two fæcal concretions—one (at one and one-half inches from the cæcum) was three-fourths inch long and three-eighths inch in diameter; the other, of nearly the same size, projected for one-fourth its length through the sloughed-off tip of the appendix. The bladder and rectum were normal, and there were no inflammatory adhesions to either, and the question in my mind was: Whence the tenesmus of bladder and rectum?

A LARGE DOSE OF SODIUM SALICYLATE.

By H. S. JEWETT, M.D.,

H. D. C——, in his eighty-second year, had been taking ten-grain doses, t.i.d., of sodium salicylate for a slight rheumatic affection. He bought three hundred and twenty grains and dissolved it in four ounces of water. Of this solution he took one fluid drachm (containing ten grains) three times a day. One day, after preparing a fresh bottleful, he drank (in a fit of abstraction) the whole amount, three hundred and twenty grains, at one dose. The only unpleasant results were excessive roaring in the ears, very active catharsis, and weakness from fright, which confined him to his room for a few days, after which he felt better, stronger, and more active than he had for several years.

DEATH FROM A.C.E. MIXTURE.

By H. S. JEWETT, M.D.

R. H——, aged forty-four, single, laborer, was admitted to St. Elizabeth's Hospital, August 25, 1895, with compound fracture of the tibia and fibula. He had been a hard drinker for many years. A.C.E. mixture was administered and the fracture was adjusted and dressed. The fragments having become displaced, A.C.E. was again administered on August 27th, and the fracture was readjusted. On August 28th A.C.E. was again administered and the ends of the bones were wired together. Although he was a bad subject, these three administrations of the anæsthetic produced no unpleasant symptoms, excepting possibly slight prolongation of the struggling stage.

For the removal of a sequestrum at the site of the injury, A.C.E. was again administered on November 7, 1895. At this time physical examination showed no lesion of the heart, and the urine contained no casts, albumin, or sugar. After a few whiffs of the anæsthetic and before consciousness was entirely lost, the patient began to struggle violently, had a slight convulsion, and ceased breathing. His head was immediately lowered; artificial respiration (by Sylvester's method) was commenced and continued for forty minutes. While this was being carried out, rhythmic traction of the tongue was made and the electric battery was used. Whiskey, strychnine, and nitroglycerin were also injected hypodermatically. The pulse continued to beat for nearly a minute after respiration had ceased. No post-mortem examination was permitted.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, November 13, 1897.

SHOULD MINISTERS PAY DOCTORS?

THAT medical men are suffering from a variety of grievances is too well known to need much recapitulation. There are so many ways of imposing on their good nature that it is difficult to particularize. Not only through the agency of dispensaries and hospitals are they mulcted of their just dues, but there are other and not less insinuating methods of abusing their benevolence. The statement has been made, and is probably near the mark, that fifty per cent. of the people will shirk paying their doctor and will lower themselves to almost any mean subterfuge in order to save a few dollars. The belief would appear to be widespread that physicians earn their fees easily, and they are in consequence looked upon as fair game by that class of the community which likes to get something for nothing. A custom prevails in this country that ministers should be considered as free from any pecuniary obligation to the doctor for services rendered. This custom has been in existence for so long a time that the fact seems to have been forgotten that this free service is only an act of courtesy on the part of the physician, and not, as the minister imagines, by any means binding. The explanation for this state of affairs is not easy to give. In bygone times there may have been fairly cogent reasons why the doctor should thus favor the clergyman. Then it might perhaps have been argued that in many instances the medical man received a *quid pro quo*—he was repaid to a certain extent by the introduction of patients. Times, however, have changed, and that argument now will hardly stand. Again, the relative financial positions of the two professions have greatly altered. At one time, before acute competition had reduced his earnings, the doctor was both able and willing to lend a helping hand to the poor minister. Nowadays it may be said with truth that their respective positions are reversed, and that the minister is as well able to pay for as the doctor is to give his services. The clergyman may not be much richer, but it is very certain that the doctor is a great deal poorer.

Still, when all has been said and done, it is not so much the custom itself as the abuse of it that hurts both the feelings and pocket of the doctor. For example, take a popular summer resort, to which people flock for a short time and where the resident practitioners hope to make their harvest, often indeed chiefly depending upon their earnings at this season to carry them through the remainder of the year. Numerous clergymen with their wives and families will visit the place, many of whom will require medical attendance. Surely in such cases it is hard on the unfortunate doctor that he should be expected to attend these absolute strangers as a matter of obligation. He will not greatly object to giving his services to the resident preachers, but that he should not feel sore at wasting his time on people he may never see again is rather too much to look for from poor human nature. A line should be drawn somewhere.

There is also said to be a lamentable lack of reciprocity about this custom; thus if a physician who has been attending a minister and any one of his family wishes to get married by him, he will in all likelihood be called upon for a fee. This is not exactly doing unto others as ye would they should do unto you.

In England the custom of free medical attendance exists, but to a much more limited extent than here. It is there regarded as a question of courtesy and not of obligation. Most of the consultants in the large towns do not take fees from clergymen, simply because they think the latter cannot afford to pay and not because they consider themselves in any way bound to give them free advice. In the country districts, however, of Great Britain, the clergyman pays the doctor just as he would his lawyer or his tradesman. This matter should be placed in its true light. It is not obligatory on the doctor to attend the minister without payment, nor is there any unwritten law to that effect. If he does so it is altogether from kindness, and it is galling to him to have the action regarded otherwise. Why should not ministers be classed in the same category as ordinary individuals? Those who cannot afford to pay should be attended free of charge, not as claiming such attendance as a right, but in the exercise of pure benevolence. On the other hand, there are no reasons why those who are able to pay should not do so. Perhaps the subject is misunderstood by them, and the true position of affairs is not thoroughly appreciated. They imagine that free attendance is their right. If their minds were disabused of this idea, and if they were convinced that by not paying they were in a manner accepting alms, with the consequent loss of self-respect, their views might undergo a considerable alteration.

THE NAVY MEDICAL SERVICE.

IT will surprise many of the friends of the naval medical service to learn that in spite of the many struggles heretofore made for naval staff rank the fight has been virtually given up and that the staff in question is apparently resigned to its fate. This is the more deplorable, inasmuch as the engineer corps, its recognized partner in the question, has gained its point, as is shown in the recent report of the committee of the line and staff appointed to consider the claim. It is useless to recapitulate what this means, either in the light of disparagement of equal relative rights or

of absolute justice to each. It may be well, however, in passing, to bear in mind the many indignities suffered by the medical service from officers of the line when questions of authoritative jurisdiction have been brought to the level of practical demonstration. It was not that the medical officer was greedy of power, but that he desired proper recognition in the enforcement of regulations affecting his own particular work with the men temporarily placed in his charge. This old-time grievance has become so much a matter of common knowledge with civil practitioners that the applications for entrance into the navy have fallen off to a degree that threatens the future efficiency of its medical service. As a fact in point there are sixteen vacancies which cannot be filled, although they have existed for a long time. Under existing circumstances it is not likely that the evil will be remedied, especially now that it is declared in a public and official manner that there is virtually no hope for the future applicant who as a professional gentleman wishes to command that respect for his position which its responsibility rightly demands.

The real trouble in obtaining men is the lack of proper rank and quarters for them on shipboard during the first two or three years. The assistant surgeons very naturally object to being messed with cadets and captains' clerks, as they are according to the present regulations, and believe they should be with ward-room officers. Until they are treated better, the navy will be short of surgeons, for few men who are capable of earning a living elsewhere will submit to such indignity.

THE ANTIFOOTBALL BILL.

The lamentable death of the Georgia student Gammon as the result of injuries received in a game of football has occasioned the passage of a bill by the house of representatives of Georgia, making it a misdemeanor to engage in the game when matches have been arranged or gate money has been demanded. The overwhelming majority vote of the lower house makes it quite probable that the senate will indorse the action and the bill will become a law. If this be the case, Georgia will set a laudable example for every commonwealth of the country. The time certainly has come when such a general movement is necessary. In view of the great number of serious accidents on the football field between college teams, it is impossible any longer to view the game in the light of innocent recreative amusement with harmless and healthful athletics as its object. Although so-called slugging has been ruled out in the new game, there is still left enough of brutal muscular force to make the alleged sport productive of the greatest variety of surgical injuries to every part of the body. In fact, there is hardly a game played in which some one of the contestants is not more or less seriously hurt. Only the severer injuries are noted, while the lesser ones serve as enlivening incidents to call forth the plaudits of an excited audience. Short of actual death on the field, not much account is taken of the hundreds of young men who are oftentimes injured for life as the result of the rough-and-tumble methods of the match. The trainers explain the number of injuries by the lack of requisite physical preparation for the contest, but in reality the more the footballers are trained the more dangerous becomes the game. It is certainly time we should look the matter fairly in the face. If we wish to develop pluck, courage, endurance, and strength, we can do so in more healthful and safer ways. It is time that the new game, with mere weight against weight, should be abolished.

THE ESTABLISHMENT OF MORE SMALL PARKS.

The advisory committee appointed by Mayor Strong to consider the practicability of creating small parks in different parts of this city as playgrounds for children, has reported favorably by recommending that a dozen or more squares be devoted to the purpose. This is an eminently wise recommendation, and its fulfilment will be of untold benefit to the thousands of children in the thickly settled districts. These breathing-spots will not only conduce to the sanitary welfare of the neighborhoods, but will doubtless have a social influence upon the parents and children that can hardly be estimated. In the latter connection the reports of the police captains are quite interesting in proving that the opening of the small parks has conduced markedly to the abolition of juvenile rowdyism, such as was formerly so intimately associated with the ordinary street education. It is also advised by the committee that playgrounds be connected with the public schools. This is a most excellent and most healthful measure in the right direction, and will tend to educate the rising generation in those elements of civilization which naturally evolve themselves in contented, healthful, and law-abiding citizenship.

ONE MORE KICK AT AN ABUSED PROFESSION.

The supreme court of Illinois has recently handed down a decision to the effect that any physician may be called from his practice at any time and forced to give expert testimony in court without compensation other than the regular witness fee. The decision was on the appeal of Dr. J. N. Dixon, of Springfield, who was fined for contempt of court because he refused to give expert testimony without adequate compensation. According to *The Journal* of Springfield, in May, 1895, Dr. Dixon was subpœnaed as an expert witness in the trial of a personal-injury suit brought against the city. The city desired to show by Dr. Dixon's testimony whether the injuries sustained would produce the result claimed by the plaintiff in the suit. Dr. Dixon refused to testify in the case unless he was paid a fee. The judge entered a ruling on the matter, deciding that the physician was not entitled to a special fee and that it was his duty to give the testimony. Dr. Dixon still refused to testify, and the court assessed a

fine of $25 against him for contempt of court. The case was appealed by Dr. Dixon to the appellate court, where the decision was sustained. The State Medical Society took the matter up, and by its direction Dr. Dixon carried the case to the supreme court. In giving his decision, Judge Creighton classed the giving of testimony with jury service and other public duties. He admitted that it is a hardship for physicians, whose time is valuable, to be compelled to attend upon trials for the usual witness fees, but he pointed out that other citizens are required to make similar sacrifices for the public good. He declared that it would be unjust discrimination to allow experts special fees, while other men were required to neglect their business and attend upon court for the fees fixed by the statute.

This same worthy judge would probably be very indignant if he were forced to sit on the bench and hand down absurd decisions for a couple of dollars a day. But lawyers are not doctors. They make no pretence of working for the love of God and the good of their fellow-men; they work to make a living and are not ashamed to say so.

INEXPERT TESTIMONY.

The editor of the *American Veterinary Review*, commenting upon some remarks in these columns anent the conflicting testimony of the alleged experts in the Luetgert trial, thinks that the trouble lay in the fact that the human anatomists were talking on a subject that they actually knew little or nothing about, namely, comparative or veterinary anatomy. The writer evidently believes that there are many veterinary anatomists in this country who could give the points of osseous differentiation between a woman and a hog offhand; indeed, he says so in nearly these words. It would perhaps be well if both sides called in veterinary instead of human anatomists at the next trial. It could then possibly be seen whether or not the hired witnesses in the first trial had testified on a subject of which they had no knowledge, when a man's life was dependent upon the nature of their testimony.

THE ADVERTISEMENTS THAT ARE UNFIT TO PRINT.

An esteemed correspondent has called our attention to a misdemeanor perpetrated by the publishers of the *New York Times*, a journal with ordinarily well-sustained pretensions to decency. The unlawful act was the publication, in the issue of October 31st, of the following advertisement:

"Professional title wanted. To purchase the name, and right to use the same, of a retired physician. Address, with full particulars, box 827, New York City."

According to the laws relating to the medical profession, which were enacted by the legislature of 1893 and which were amended by the legislature of 1895, entitled "chapter 661 of the laws of 1893, chapter 25 of the general laws," such an advertisement becomes not only a misdemeanor for the person who purchases, but for all those who aid or abet it. Thus, chapter 398 of the laws of 1895, which is an amendment to section 153, reads:

"Penalties and their collection. Any person who, not being then lawfully authorized to practise medicine within this State and so registered according to law, shall practise medicine within this State without lawful registration or in violation of any provision of this article; and any person who shall buy, sell, or fraudulently obtain any medical diploma, license, record, or registration, or who shall aid or abet such buying, selling, or fraudulently obtaining, or who shall practise medicine under cover of any medical diploma, license, record, or registration illegally obtained or signed or issued unlawfully or under fraudulent representations or mistake of fact in the material regard; . . . on conviction thereof shall be punished by a fine of not more than $250 or imprisonment for six months for the first offence; and on conviction of any subsequent offence, by a fine of not more than $500 or imprisonment for not less than one year, or by both fine and imprisonment."

Very probably the proprietors of the *New York Times* did not know of the unlawful nature of their action when they sold the space for this advertisement, but they knew they were aiding and abetting a meretricious quack and a dishonest rascal—one who, if he succeeded by their help in his unlawful quest, would be in a position to disobey the laws of the State and to jeopardize the lives of those who might be led to trust him. Certainly the publication of such an advertisement by a journal which claims to be reputable and even superior in virtue to its rivals is extraordinary. This paper purports to have "all the news that's fit to print," but its high morals are evidently not proof against the seductions of cash advertisements.

INHIBITION OF OSCULATORY REFLEXES.

A young physician, a member of the house staff in Bellevue Hospital, is in considerable trouble in consequence of a heinous charge of forcibly kissing one of the trained nurses in that institution. The authorities have promptly suspended him in order that the case may be properly investigated. So far as the facts go it would seem to prove that doctors, especially young ones, are intensely human, even if they are not strictly philosophical. There is perhaps less excuse for a professional man who may be in provoking contact with constant temptation to forget his dignity than for ordinary mortals. He is supposed to have a special training in inhibiting his emotional centres and in controlling his osculatory and other responsive reflexes. But, psychologically speaking, when toeing the dead line of professional propriety, there is often a propensity to step beyond in a dangerous area of culpable indiscretion. The only excuse may be that the unfortunate criminal is still young and has a great deal yet to learn. When the positive pole of temptation and the negative pole of opportunity are

in close proximity, there is always a means of preventing explosions by the interposition of a suitable non-conducting material of impervious unconcern. Consequently it was all wrong, and very wrong, for the young doctor to be off his professional guard. It is entirely inexcusable for him to plead the baby act by magnifying any possible provocation, great as that might have been. The gauze cap, the spotless apron, the graceful carriage, and the demure demeanor of the unsuspecting victim have nothing to do with the result. It is sad to think that the young man should commence a promising career with such a stain on his professional escutcheon. The constant menace of danger should have doubled his means of resistance to folly. Whatever may be the outcome of this deplorable case, the grand and fundamental principle of professional indifference to all amatory demonstrations should be rigidly maintained; otherwise all the desirable and well-trained nurses may desert our hospitals and leave our patients to the care of the shiftless, unclean, and irresponsible chore woman.

TUBERCULOSIS IN THE KANSAS STATE AGRICULTURAL COLLEGE HERD.

Our attention has been called to a report on tuberculosis in the Kansas State Agricultural College herd, which appeared in our issue of September 11th. This report is said to have been partly incorrect. A journal containing a correct account has been sent us from the college. We gather from this that although the whole herd of cattle is affected with tuberculosis and the condition of the hogs and sheep is suspected, no mention is made of any human being having become infected. On that point we must have been misinformed. We may add that a committee with unlimited authority has been appointed to investigate fully and thoroughly the affairs of the college.

News of the Week.

The Yellow Fever.—The weather in the South has until the last few days again been warm, but that seems to have had no unfavorable effect upon the progress of the yellow fever, which is evidently waning. The new cases are rapidly diminishing in number, although the mortality, as is usual toward the close of an epidemic, is increasing somewhat. It is believed that the fever will have disappeared entirely by the middle of this month, and the New Orleans board of health has announced that it is now perfectly safe for persons to enter the city. Among the most recent victims of the fever is Dr. I. M. Wright, of Biloxi, Miss., whose death was announced on November 8th. There have been heavy frosts at Memphis, and all quarantine restrictions have now been raised. Throughout the South also the shotgun quarantines are being abolished, passenger and freight trains are moving again, and business is being resumed generally. The millions of dollars that have been lost through this senseless fright are, however, lost for good and all.

Ambulance Surgeon Tracy, of the New York Hospital, in responding to a street accident "hurry call" one day this week, found in the injured man his long-lost brother. In a town of this size, where there are so many other men who it might have been, the incident is worthy of note.

Post-Graduate Medical School and Hospital.—The professorship of nervous and mental diseases in the New York Post-Graduate Medical School, made vacant last summer by the resignation of Dr. Charles L. Dana, has been filled by the election of Dr. Joseph Collins.

New York Foundling Hospital. — Dr. Henry C. Coe has been appointed consulting gynæcologist to the New York Foundling Hospital, to fill the vacancy occasioned by the death of Dr. Lusk.

New Army Surgeons.—Six men have passed the examination held recently in Washington for appointment as assistant surgeons, and will soon be commissioned by the President. Seven vacancies existed, and over forty candidates appeared for them. The young men who will be appointed are George Rauchfuss, of New York; Bernard S. Higley, of Ohio; Henry Page, of Maryland; Bailey K. Ashford, of Washington; Henry H. Weber, of Massachusetts; and Jere B. Clayton, of California. The new assistant surgeons will be required to take a course of instruction in the Army Medical School before being assigned to regiments. There is still one vacancy in the medical corps, and two more will occur this month by the retirement of Lieutenant-Colonel Walters and Major Corson.

The Plague in India is spreading rapidly, and now threatens all the northern and central part of the peninsula. Much apprehension has been caused by its appearance at Hurdwar on the Ganges, which is a centre for pilgrimages and is frequented by great crowds drawn from all parts of India.

Gymnastics in the College Curriculum.—The Yale faculty has instituted compulsory gymnasium work for the freshman class. Dr. Anderson will have charge of the course, which will consist of two hours a week, lasting through the first half of the second term. Men who are in regular training for the athletic teams and those who are physically disabled will be excused. The class work will consist partly of dumbbell or wand exercises, and later heavy gymnastics, to which especial attention will be paid.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending November 6, 1897. October 30th.—Passed Assistant Surgeon Adrian R. Alfred detached from waiting orders at his home, Jeddo, Mich., and ordered to marine recruiting rendezvous, San Francisco, Cal. November 2d.—Surgeon P. Fitzsimons ordered to duty as a member of the board of inspection and survey, Washington, D. C., November 8th; Assistant Surgeon G. D. Costigan detached from the *Lancaster* and ordered to the *Indiana*.

The Guild of St. Barnabas.—The annual meeting of this association of nurses was held a few days ago in Orange, N. J. The active membership of the guild, composed entirely of hospital nurses, now numbers thirteen hundred.

The Craig Colony for Epileptics at Sonyea, Livingston County, N. Y., closed its fourth fiscal year, September 30, 1897. There were at that time two hundred and fourteen patients in the colony, the majority of whom had been transferred from the various county houses throughout the State. New buildings are in course of construction, which when completed will enable the colony to accommodate one hundred and forty additional patients, making the total population about three hundred and fifty. It is estimated by State charity officials that this number represents about one-third of the total number of epileptics now on public charge throughout the State. A laboratory for the use of a pathologist and pathological chemist is being constructed. Dr. Christian A. Herter, of New York, has been appointed pathological chemist, and Dr. Ira Van Gieson, of New York, consulting pathologist to the colony. Dr. William P. Spratling continues as medical superintendent of the colony. Dr. Frederick Peterson, of New York, has been re-elected president of the board of managers.

The New York State Association of Railway Surgeons.—The seventh annual meeting of this society will be held in the building of the Academy of Medicine, in this city, on Tuesday, November 16, 1897. The special topic for discussion will be "Traumatic Neurasthenia," and several papers on other subjects are announced in the programme. The president of the association is Dr. J. Frank Valentine, of Brooklyn, and the secretary, Dr. C. B. Herrick, of Troy.

A New Swindle.—A young man in this city has recently adopted a new way of making a living, which has worked well in a few cases, but is not likely to survive publicity for a great length of time. He delivers a package to a man in his office, pretending that it contains medicine ordered by the victim's wife, and after collecting a moderate sum, varying in amount from fifty cents to two or three dollars, departs. The packet is inclosed in an American District Telegraph Company's envelope, and when opened by the mystified wife in the evening is found to contain a few grains of corn.

The Final Echo of the Medical College Consolidation Scheme.—On November 4th the regents of the university at Albany, in accordance with the request of the New York University and Bellevue Medical College, reconsidered the ordinance of April 8th, providing for the consolidation of the two medical schools, and the matter was laid on the table.

Medical Sufferers from Yellow Fever. — Several young practitioners have been stricken with the prevailing fever. Fortunately we have no fatality to record for October. Drs. J. Barnett, M. J. Magruder, H. Olliphant, Otto Lerch, E. P. Lowe, C. J. Miller, S. G. Kreeger are among those who have been attacked, but we are happy to state that they have all made good recoveries.—*New Orleans Medical and Surgical Journal.*

Surgeons for Inland and Coasting Steamers.—The Newport (R. I.) Medical Society has taken up the question of ship's surgeons, and urges upon Congress the passage of laws compelling passenger steamers in the inland and coastwise trade to carry surgeons. The committee states that some of the Sound steamers sometimes carry as many as a thousand passengers on the boat. Although the trip lasts, as a rule, only nine hours, still there are times when the boats are delayed for hours, and it would be in keeping with the humanity of the times to have a physician on the boat. All the steamboats on the Sound, on the Great Lakes, on the long rivers where passengers are often for days without medical aid, practise the same economy. Our seagoing steamers running South, as a rule, have no physician on board. Some employ the device of employing the purser as surgeon, and when he is pressed, owing to his numerous duties, appoint at times a man who is not any more qualified than the purser to act as surgeon's assistant. Such steamers as those running from Philadelphia to Portland carry often thirty or forty passengers and a crew of twenty or more, and, being often out three days, should have a physician on board. It is a very common practice with all the transportation companies to rely upon travelling physicians to care for sick seamen and passengers. They receive no compensation for their services and are not even returned their passage money. It is a question, however, whether in such a case the company could not be compelled to compensate the physician for services rendered at the request of the captain or other responsible employee.

Sir Alfred B. Garrod cannot be called a rolling stone. He recently celebrated the completion of his fiftieth year in medical practice, and it then was said that he had lived the half-century in the same house in Harley Street, never having experienced the delights of house moving.

Yellow-Fever "Experts."—Since the outbreak of yellow fever occurred in the South last August, legions of so-called "experts" have sprung into existence, and have foisted themselves upon press correspondents and a patient public to such an extent that there is really a possibility that there are now more experts than there are or have been yellow-fever patients. These gentlemen have been all so antagonistic in their diagnoses, and have so freely expressed themselves pro and con whenever a fresh outbreak of fever was reported, that the poor befuddled public hardly knew what to believe.—*Memphis Medical Monthly.*

The Difficulty of Enforcing Isolation in New Orleans.—Correspondents of the Italian papers from New Orleans say that one great cause of the spread of yellow fever in that city is the obstinacy with which the Italian residents resist the efforts of the health authorities to isolate the sick. In many cases it has been necessary for the health officers to go through the

Italian quarter under the protection of the police, so incensed are the ignorant inhabitants by the enforcement of the necessary precautions. In many cases they elude the vigilance of the inspectors and smuggle the sick from one house to another, spreading the disease in every direction.

Physicians to Spare.—A paragraph is going the rounds of the daily press, to the effect that Columbus, Ohio, with one hundred thousand inhabitants, has thirteen hundred physicians, or one to every seventy-seven persons.

In Favor of National Control of Epidemics.—The board of supervisors of Warren County, Miss., recently adopted unanimously resolutions declaring it "the deliberate opinion of this board that the entire subject of quarantine against yellow fever and other infectious diseases of foreign origin ought to be under the paramount control of the United States, the experience of the present system and spread of yellow fever this year furnishing conclusive evidence that the several independent boards of health of the States bordering on the Gulf of Mexico cannot be safely relied upon to prevent the introduction and spread of infectious and contagious diseases."

The American Electro-Therapeutic Association.—At the seventh annual meeting of this society, held at Harrisburg, Pa., the following officers were elected: *President*, Dr. Charles R. Dickson, 343 Sherbourne Street, Toronto, Ontario; *First Vice-President*, Dr. Frederic Schavoir, 8 Atlantic Street, Stamford, Conn.; *Second Vice-President*, Dr. Caleb Brown, Sac City, Iowa; *Treasurer*, Dr. Richard J. Nunn, 119½ York Street, Savannah, Ga.; *Secretary*, Dr. John Gerin, 68 North Street, Auburn, N. Y. The next meeting will be held in Buffalo, N. Y., on September 13, 14, and 15, 1898.

The Movement for the Repression of Tuberculosis.—On completing the twenty-fifth year of his reign, the King of Sweden has given 2,200,000 kroner to be applied toward the abatement of tuberculosis by the erection of sanatoria and other means.

Brooklyn Police Surgeons.—Brooklyn is to have four police surgeons at $3,000 a year each under the new charter. The civil-service commissioners have named November 19th as the date for the competitive examination for the places. If the same proportion prevails as at the recent examination to fill vacancies on the New York board of police surgeons, there will be one hundred and sixty-four competitors.

Contract Medical Practice Denounced.—The Somerset County District Medical Society, at the quarterly meeting held in Somerville, N. J., October 28, 1897, passed the following resolutions:

"*Whereas*, The members of this society are frequently importuned to make contracts to attend private families, the members of various societies, lodges, etc., at reduced rates; therefore be it

"*Resolved*, That it is the expressed sentiment of this society that it is derogatory to the dignity of the medical profession for any regular physician to subscribe to any such contract;

"*Resolved*, That any member of this district society who hereafter makes any contract or agreement to attend the members of any family, society, lodge, or other organization for a fixed sum shall be considered as violating the spirit of the code of ethics, and such violation shall be considered sufficient ground for action by this society in accordance with section 16 of the bylaws of said society;

"*Resolved*, That this society earnestly recommends the cancellation of any existing contracts which may be opposed to the spirit of these resolutions; and be it further

"*Resolved*, That nothing in these resolutions shall be construed as affecting any contract of a local surgeon for any railroad company or of any township or county physician, or any position under municipal, State, or national government."

An International Leprosy Society.—At the recent leprosy congress in Berlin, a commission was appointed to prepare plans for the formation of an International Leprosy Society. Professor Virchow is the president of the commission.

An Earthly Paradise is what *The Lancet* calls Montagu Square in London, the dwellers on which were empowered, by a private act passed in the reign of George III., to bring offenders before the magistrate for annoying people by selling newspapers "and noisily endeavoring to attract attention that they had newspapers for sale." Three boys were charged with this offence, and their respective mothers made to enter into their recognizances in £5 to bring them up for judgment if called upon. Would that New Yorkers had the privilege of the Montagu Squarers of damping the hideous tones of the loud-mouthed extra cries!

Subscriptions to Charity in England.—During the past year there have been public collections for charitable objects in England amounting to about $4,000,000. Of this amount $2,750,000 was for the Indian famine fund, about $1,000,000 for the various jubilee funds, and the balance for the Hospital Sunday fund and the Maidstone and the Montserrat relief funds.

The Gloucester Small-Pox Epidemic.—The report of the commission investigating the epidemic of small-pox, which served as England's celebration of the Jenner centenary, has been published, and affords little consolation to the antivaccinationists. According to the official figures, the unvaccinated persons attacked stood to the vaccinated attacked in the proportion of ninety-six to four, while among the entire non-adult population, those attacked and those not attacked, there were eighty-three unvaccinated ones to seventeen vaccinated.

Pay by the Patient and Not by the Visit.—In Austria, where physicians' fees are fixed by law and are therefore small, great complaint has been made because, if a physician happened to attend several members of one family at the same time, he could col-

lect only one fee. To obviate this custom, which has naturally caused physicians much loss, it has lately been decided that when there are two or more patients in a family, the doctor can charge a florin per patient instead of per visit.

The Dangers of Self-Treatment.—The postmaster of Denver died on November 1st from an overdose of morphine pills, which he had taken the evening before, supposing them to be cathartic pills.

The Cumberland County (N. J.) Medical Society.—The semi-annual meeting of this society was held at Bridgeton, N. J., October 12th, with the president, Dr. H. W. Elmer, in the chair. A paper on "Some Favorite Formulæ" was read by Dr. J. W. Wade, of Millville, N J. Dr. Edward Fogg, of Roadstown, and Dr. L. H. Hummel, of Greenwich, were elected to active membership. Dr. J. Chalmers Da Costa and Dr. David Riesman, of Philadelphia, were elected to associate membership.

New York Maternity Hospital.—Dr. Simon Marx has been appointed to the position of attending surgeon to the New York Maternity Hospital.

New York Obstetrical Society.—At the late meeting of the New York Obstetrical Society the following fellows were elected officers for the ensuing year: *President*, Dr. W. Gill Wylie; *First Vice-President*, Dr. J. C. Edgar; *Second Vice-President*, Dr. A. M. Jacobus; *Recording Secretary*, Dr. LeRoy Brown; *Assistant Recording Secretary*, Dr. George W. Jarman; *Corresponding Secretary*, Dr. E. B. Cragin; *Treasurer*, Dr. J. Lee Morrill; *Pathologist*, Dr. George C. Freeborn.

Philadelphia County Medical Society.—A stated meeting of the Philadelphia County Medical Society was held on October 27th, the president, Dr. James Tyson, in the chair. Dr. Herman B. Allyn read a paper entitled "Typhoid Fever Occurring in a Tuberculous Subject and Complicated with Nephritis." He reported the case of a man presenting symptoms of typhoid fever, together with a positive reaction to the Widal test, in whose sputum tubercle bacilli were repeatedly found. Recovery from the typhoid fever took place, but death resulted in consequence of the tuberculosis. Upon post-mortem examination pronounced tuberculous lesions were found in the lungs, but without any evidence immediate or remote of disease of the intestines. Especial interest attached to the possibility of concurrence of two distinct infections. Dr. J. W. Croskey reported a case in which a bit of wood almost one inch long and one-fourth of an inch thick was removed from the upper lid, in which it had been lodged under the retrotarsal fold for a period of eight months. The conjunctivitis which had been present disappeared soon after the removal of the foreign body.

Pathological Society of Philadelphia.—A stated meeting of the Pathological Society of Philadelphia was held on October 28th, the president, Dr. W. E. Hughes, in the chair. Dr. John B. Roberts exhibited a specimen of internal strangulation of the small bowel by a thread-like band arising from the lower portion of the ileum and attached to the anterior abdominal wall. Dr. J. M. Swan exhibited a specimen of tuberculosis of the kidney, tubercles being distributed in the course of the blood-vessels through medulla and cortex. The second kidney was in a state of chronic parenchymatous inflammation, but free from tubercle. Dr. Swan exhibited also a dissecting aneurism of the arch of the aorta. Dr. E. R. Schreiner exhibited a huge malignant new growth of the pyloric extremity of the stomach, with secondary deposits in the liver and also a small pedunculated papillomatous tumor of the stomach. Dr. Riesman exhibited a brain displaying an abnormally long basilar artery, with anomalous branches, and also a brain presenting a small translucent tumor behind the pituitary body. Dr. J. H. Musser exhibited a huge melanotic sarcoma of the liver, weighing seventeen pounds, from a case in which a similar neoplastic formation of the choroid had necessitated removal of the eyeball more than a year previously.

Miss Susan J. Brayton is one of the matriculants in the New York Veterinary College this year. She is the daughter of a stock farmer, and if she takes the full course will, it is said, be the first woman veterinary surgeon in America.

Philadelphia Polyclinic.—Dr. H. Augustus Wilson has resigned the chair of general and orthopædic surgery in the Philadelphia Polyclinic, and has been made emeritus professor. Dr. J. P. Crozer Griffith has resigned the chair of clinical medicine. Dr. Charles W. Burr has been elected professor of neuro-pathology; Dr. William G. Spiller, professor of diseases of the nervous system; and Dr. J. W. McConnell, associate in diseases of the nervous system.

An Apology.—Our esteemed contemporary, the *Medical Age*, chides us for commenting upon an article which appeared in its columns nearly a year ago. We did not know that the editor regarded the contents of his journal as of such ephemeral value, and we shall endeavor in future not to disturb the quiet of the buried past. We should not have offended in this instance had not the author kindly favored us with a reprint of his paper.

Honors for Colored Physicians.—Dr. W. B. Fayerman, of Atlantic City, has been elected a member of the Atlantic County Medical Society. He is the first colored physician ever accorded this honor. New Jersey has now three colored physicians members of county medical societies—Dr. Fayerman, of Atlantic County; Drs. Rholerfort and Wormley, of Essex.

College of Physicians of Philadelphia.—A stated meeting of the College of Physicians of Philadelphia was held on November 3d, the president, Dr. J. M. DaCosta, in the chair. Dr. John Ashhurst, Jr., read a memoir of the late Dr. Theodore G. Wormley, and Dr. Arthur Van Harlingen read a paper entitled "Folliculitis Nuchæ Sclerotisans (Acne Keloid)," also exhibiting a specimen of this variety of growth.

Bucks County (Pa.) Medical Society. — At the annual meeting of the Bucks County Medical Society, held at Doylestown, Pa., on November 3d, Dr. Frank B. Swartzlander, Jr., read a paper on "The Serum Diagnosis of Typhoid Fever;" and Dr. William R. Cooper, of Point Pleasant, Pa., and Dr. J. H. Fretz, of Stockton, N. J., made clinical reports. The following officers were chosen for the ensuing year: *President*, Dr. J. N. Richards, Fallsington; *Vice-President*, Dr. C. D. Fretz, Jr., Sellersville; *Secretary*, Dr. A. T. Myers, Blooming Glen; *Treasurer*, Dr. Frank Swartzlander, Doylestown; *Board of Censors*, Dr. A. M. Cooper, Point Pleasant; Dr. William Stavely, Lahaska; and Dr. George M. Grim, Ottsville.

Obituary Notes.—Dr. Joseph E. Culver died at his home in Jersey City on November 1st, of pneumonia, at the age of seventy-four years. He was a graduate of the College of Physicians and Surgeons in this city in 1849. He was one of the founders of the Hudson County Medical Society, and was a member of the Pathological Society and of the Neurological Society in New York. Four sons, two of whom are physicians, survive him.—Dr. James G. Sloan, a member of the Pennsylvania State legislature, died at Monongahela City, Pa., on November 2d, at the age of fifty-six years. He was graduated from Jefferson College in 1862, and a week later he enlisted in company G, Pennsylvania volunteers, serving until the close of the war. He then served for four years in the land office bureau of the interior department at Washington, D. C., and was graduated from Georgetown Medical College in 1869. He was elected a member of the Pennsylvania legislature in 1896.

A Mattei Cancer Hospital.—The late Count Mattei, who apparently really believed in his "electric" treatment of cancer, left directions in his will for the foundation of a hospital in which cancer sufferers may be treated according to his methods.

Medical Practice Regulations in Illinois.—The State board of health of Illinois has decided that after May 1, 1898, all non-graduate applicants for license to practise medicine and surgery, who are examined in accordance with the provisions of the medical practice act, in addition to the requirements already exacted, must present as evidence of a satisfactory preliminary education either (1) a diploma or certificate of graduation from a high school; (2) a certificate of having passed the matriculation examination to a recognized literary or scientific college; or (3) a certificate of successful examination by the faculty of any reputable university or college of arts or science (not members of a medical college faculty), by the State superintendent of public instruction of Illinois, or by the principal of a high school in Illinois, in the following branches: English grammar, arithmetic, elementary physics, United States history, geography, and Latin (equivalent to one year in a high school). Each candidate will also be required to present a certificate from a medical college in good standing with the board, attesting that the applicant has (1) pursued the study of practical anatomy in said college for at least one term and has made dissections of the entire cadaver; (2) taken at least one full course in operative surgery and practical obstetrics; and (3) personally attended six or more cases of labor. Bacteriology has been added to the subjects of the non-graduate examination.

The Chewing-Gum Habit, we learn from the *British Medical Journal*, has been taken up in England by many young women—students, actresses, and others—who have become inveterate chewers. A few days ago an inquest was held at Lincoln on a child, eight years of age, who died from the effects of eating a pellet of the substance. The symptoms preceding death were those of gastritis, and at the post-mortem examination it was found that the mucous membrane of the stomach was inflamed and that there was much local peritonitis. The coroner pointed out that the distribution of such dangerous stuff to young children was a very improper proceeding, and the jury, in indorsing his remarks, added that in its opinion the sale should be absolutely prohibited.

Tuberculosis in Cigars.—According to the newspapers, Dr. J. C. Spencer, bacteriologist of the board of health of San Francisco, reports that he has discovered the bacilli of tuberculosis in cigars.

Bequests to Hospitals.—Under the will of the late George M. Pullman, thirteen hospitals and charitable institutions of Chicago will receive $10,000 each.

Dr. Marion Hunter, niece of Sir William Hunter, has been appointed the female member of the British medical corps sent out to combat the plague in India. She was until recently the only woman physician holding the Cambridge diploma of public health.

The Southern Surgical and Gynæcological Asssociation held its tenth annual meeting at St. Louis, Mo., on November 9, 10, and 11, 1897.

Typhoid Fever in a London Hospital.—Eighteen or twenty of the nurses and ward helpers at University College Hospital, London, have recently suffered from typhoid fever. The outbreak was due to a singular piece of stupidity on the part of the authorities. All those attacked took their meals in a temporary dining-room, which had been provided for them because certain houses in which they had been previously accommodated were pulled down on account of the rebuilding of the hospital. The water which had been used in this room for drinking, instead of being taken from the main, as is usual throughout the hospital, was drawn from a cistern which became contaminated

Yersin's Antiplague Serum.—It is reported from Bombay that Yersin has had much success with his antiplague serum, the only cases not amenable to treatment being those which were seen too late, the disease having already become firmly established and the patient being practically moribund.

Many Want, Few Get.—A civil-service examination for appointment on the staff of police surgeons was held last week at police headquarters in this city. There were two vacancies, and the competitors numbered eighty-two.

Society Reports.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Abstract of Proceedings of the Twenty-Fifth Annual Meeting, Held in Philadelphia, October 26, 27, 28, and 29, 1897.

First Day—Morning Session.

The association met at Hotel Walton, and was called to order by the president, Dr. Henry B. Horlbeck, of Charleston, S. C.

After the transaction of some routine business, the reading of reports and papers was begun.

Report of Committee on Steamship and Steamboat Sanitation.—This was read by Dr. Frederick Montizambert, general superintendent of quarantine of the Dominion of Canada, in which he directed attention to the bedding of passengers—those portions of it which are not regularly laundried, blankets, mattresses, and pillows, saying they should be freely exposed to the air, and, if possible, to the sunshine after each trip. The somewhat common usage on inland steamboats of having the dining-room on a deck below the water line was not to be commended. Such a position rendered proper cleanliness and ventilation more difficult and tended to unwholesomeness. Reference was made to the all-important matter of the exposure of the travelling public on steamboats, as elsewhere, to the danger of contracting disease from fellow-travellers suffering with consumption, who in their expectorations scattered infectious material broadcast. Objectionable and indefensible as it was at all times, with steamboat saloons closed and artificially heated, the expectorator's filthy habit became especially dangerous to other passengers. The sputa drying on the decks rose as dust to be inhaled, and to add to the great list of the victims of this fell destroyer of mankind. All spittoons should contain water or a disinfectant, which should be frequently changed. With the advancing education of the general public in the knowledge and belief in the contagiousness of consumption, and the methods to be employed to limit and prevent its spread, an ever-increasing degree of success might be confidently hoped for.

A Study of Yellow Fever from a Medico-Geographical Point of View.—Dr. Eduardo Licéaga, president of the supreme board of health of Mexico, contributed this paper, which was read by Dr. Gihon in the absence of the author. The writer said in part that in the port of Vera Cruz, which, as had already been shown, could be considered one of the sources in which the yellow-fever germ obtained a spontaneous growth, only three cases of the disease had appeared during a period under study, and these three cases occurred within the month of June. With respect to other points on the Gulf coast, and especially the ports, it could safely be asserted that during the period covered by this report not a single case of yellow fever had presented itself. Passing to the Pacific coast, and bearing in mind the terrible epidemic that in the year 1884 desolated the coast, the supreme board of health of Mexico had taken especial care to prevent the disease from being imported from the Central American countries, where unfortunately it now prevailed in an epidemic form. Difficulties were still encountered in making an exact diagnosis between yellow fever and certain forms of paludic infection that in hot countries assume a very similar aspect and the serious character that is generally borne by that disease, so much so that even persons who were accustomed to observe the two affections were often uncertain as to the diagnosis. These doubts, the speaker hoped, would be dissipated in the future by reason of the discovery of the yellow-fever microbe by Sanarelli. A knowledge of the cause of the disease would not only allow us to make an exact diagnosis, but would doubtless facilitate the means for attacking it in an effective manner.

D. Samuel H. Durgin, of Boston, spoke of the importance of closer and more careful bacteriological work in the study of yellow fever.

The Drainage, Plumbing, and Ventilation of Public and Private Buildings.—A paper on this subject was read by Mr. J. W. Hughes, of Montreal. The author confined himself to the ventilation of the plumbing-system of a building, or more correctly, that part of a plumbing-system which served for the conveyance of the house wastes known as sewage, and that were to be finally disposed of, as far as any particular building was concerned, when they reached the public sewer. It was no more possible to lay down rules covering every contingency arising in scientific plumbing and ventilating than it was to apply fixed rules to the practice of medicine. The principles of scientific medicine and plumbing were fixed, but the application of these principles called for the intelligence acquired by education and developed by practice. Much injury had been done by attempting to frame plumbing-laws which would apply to every case. If the association would make a study of the general principles covering this question and embody them in a code having its indorsement, leaving the practical application of those principles to those whose special duty it was to apply them, much good would result.

First Day—Afternoon Session.

Dr. John L. Leal, health officer of Paterson, N. J., followed with a paper on the same subject, in which he emphasized three points bearing upon the question of ventilation: 1st. That every building intended for occupancy should have some special means of ventilation. 2d. That these means should be commensurate with the requirements of any particular building. 3d. That the more simple and uncomplicated the means used, the more successful was likely to be their operation. The objects of plumbing were: 1st, the immediate withdrawal from a building of certain waste products of life, the presence of which would prove detrimental to health; and, 2d, to prevent harm to the inmates of the said building arising from these products after removal, through the means of their removal. Not only were we threatened by the presence of these substances, but we were also threatened by certain dangers inherent in the best system at our disposal for ridding ourselves of them.

Report of the Committee on Car Sanitation.—This report, by Prof. S. H. Woodbridge, of the Institute of Technology, Boston, was read by Dr. Durgin in the absence of the author. The author stated that something like interstate agitation and regulation were requisite to any legislative advancement in this field of hygienic improvement. For this reason it seemed the better way that the movement should originate within or be fostered by some strong railroad corporation which would set the pace for other railroads eventually to put themselves in step with. The writer described a new type of improved parlor and sleeping car which had been devised.

First Day—Evening Session.

To this session the public was invited. Prayer was offered by Rev. William N. McVickar, D.D., of Philadelphia.

Dr. Benjamin Lee, in the absence of Governor Hastings, welcomed the members and visitors on the

part of the Commonwealth, and Mayor Warwick extended to them the hospitality of the city. The mayor referred feelingly to the life work of the late Dr. William H. Ford in the cause of municipal sanitation, after which the address of President Horlbeck was delivered.

Speaking of the progress made in the study of disease, President Horlbeck said that the theory based upon the humors of the blood had given place to a knowledge of the denizens of the blood, which were being recognized as surely as the flora and fauna of our fields. The microscope gave us the keynotes of our temporal welfare. He then gave a history of the association from its organization in 1872, which he said had grown until there were now one thousand eight hundred and forty-four names enrolled in its membership. During its existence some of the most important discoveries in the domain of medicine and surgery had been made, and the science of bacteriology had had its birth and development. Since the last annual meeting in Buffalo the method of diagnosticating typhoid fever, as discovered and described by Widal, of Paris, had been elucidated by Wyatt Johnston, of Montreal. During the twenty-five years of the life of the association the processes of taking care of contagious diseases had entirely changed. It was now an essential feature of practice in all communities to confine all such cases to the individaul affected. He next dwelt upon the necessity for a pure water supply, and then passed on to the consideration of quarantine methods. He recommended a government commission on yellow fever. It was estimated that over ninety-five per cent. of all the yellow fever cases that had reached our shores had come from Havana. A committee of the association had been appointed to bring the vital question before the governments of this country and to urge the governments of the countries interested to prompt action in this matter. This would seem to be the occasion when not only the recommendations of the committee on yellow fever should be carried out, but also the association should make a demand on our general government to the effect that a commission of expert bacteriologists be sent to Havana and Rio and be kept there until the materies morbi had been discovered, until the secrets of this dread disease had been unfolded. The examples of other countries in the solution of the problems involved in cholera, tuberculosis, bubonic plague, and leprosy were noted, and the question was asked, why should we not solve the problems of yellow fever? He recommended that a committee from the association be appointed to wait upon the President of the United States with a view to carrying out this idea. Finally, reference was made to the experiments carried on by the State board of health of Massachusetts at Lawrence, on the utility of filtration of water supply with reference to the removal of typhoid germs, the average result being the removal of ninety-eight and a half per cent. of the germs. A diminution of sixty per cent. in typhoid cases at Lawrence had been the result of sand filtration.

Second Day—Morning Session.

Report of the Committee on Pollution of Water Supplies.—Dr. Charles Smart, of Washington, D. C., read the report, which stated that the committee had been chiefly engaged in perfecting the standard methods of bacteriological research. The committee felt that it should be discharged from its duties, and that a new one should be appointed, which should consist of a couple of men who were practically acquainted with municipal water supplies, a couple more who knew effectively the chemical aspects of the subject, and, finally, a like number who knew, as it should be known, the bacteriology of the subject. The committee had, however, announced the bacteriological formulæ for use in laboratories. In accordance with the suggestion the committee was discharged.

Disinfectants.—Prof. Franklin C. Robinson, of Maine, spoke on the subject of disinfectants. He said he could not help noting how rapidly the knowledge and use of formaldehyde had spread. Only one year ago it was practically unknown in the United States. There was no apparatus for generating it in quantity except the one that was exhibited then. Now probably most, if not all, of the members had used it. He ventured to predict that we were far from knowing all about it, and that a year from now greater progress would be seen than during the past year.

Dr. E. A. de Schweinitz, of Washington, D. C., followed with a paper on the determination of the amount of formaldehyde yielded by the formaldehyde lamp; and Prof. S. Burrage, of Lafayette, Ind., made some remarks on fumigation experiments with formaldehyde.

Diagnosis of Small-Pox.—Dr. Frank W. Wright, of New Haven, read this paper. He said that an early diagnosis of small-pox was of great importance. Next to vaccination this was the most essential factor in preventing the disease from spreading. If all cases of small-pox were typical it would not be difficult to make a correct diagnosis; but in these days of general vaccination typical small-pox was seldom seen, the great majority of the attacks being modified by former vaccinia and commonly spoken of as varioloid; but we might call them modified small-pox. If by chance a health officer should fail to recognize a case of small-pox and the disease should spread, he would be subjected to very severe criticism and would probably be removed from his position in disgrace. On the other hand, if he should declare some disease that resembled modified small-pox as that disease and future events proved that a mistake had been made, he would be just as severely criticised, and would probably have to defend himself in a suit for damages.

Second Day—Afternoon Session.

The Barber Shop as a Menace to the Public Health.—Dr. A. Walter Suiter, of Herkimer, N. Y., read a paper with this title. It seemed that the time had arrived when the attention of public health authorities should be called to that part of hygiene which applied to the barber shop. The first attempt of modern times to regulate sanitarily the operations of the barber shop was recently made in the city of Paris. As a public regulation and by direction of the sanitary authorities, an order had been promulgated requiring that for the protection of the public specific rules of asepsis and disinfection shall be observed in all shops. One evening, several years ago, a sheepish-looking individual shuffled his way into the author's waiting-room and requested a prescription. He was observed to be suffering from disease and presented a most unattractive appearance; his face was literally covered with eruptions and his mouth and lips were ulcerous in high degree with mucous patches. The man's case was disposed of and he was gladly dismissed. Having to take an early train, Dr. Suiter shortly afterward proceeded to the barber shop to prepare for his toilet. His barber's chair was occupied and he sat down to await his call. As the occupant was about to arise he was startled to observe the very patient for whom he had prescribed an hour before. It is needless to say that he took his departure. Then and there he resolved that his face should never again be shaved by a barber.

Meat Inspection.—Prof. Leonard Pearson, of Philadelphia, discussed the subject of meat inspec-

tion. Reference was first made to the amount of meat consumed by the various peoples of the world and to the methods of inspection followed in Europe and in America. Since the bacterial origin of many diseases had been demonstrated, and the close relationship of many of the diseases of man and animals had been established, the importance of rational meat inspection had been greatly emphasized.

Dr. Edward Jackson, of Philadelpnia, spoke of eye strain from poor window glass, and said the bad influence of defective window glass was intensified by the eye having to look through different parts, causing different kinds of strain, with the result that the eye could not adjust itself so as to work to the best advantage. Even if the defects in the glass were comparatively slight, at a certain distance they would cause serious strain similar to that of astigmatism.

Dr. E. P. Lachapelle, of Montreal, followed with the report of the committee on transportation of diseased tissue by mail, in which he said that the postal authorities of Canada had lately given their consent to the use of the mails for this purpose, this result being largely due to the valuable help received from the newly appointed deputy postmaster-general, who, being a physician, was quite *au fait* as to the importance of the demand. As regarded the United States it might be said that, since the use of the mails had been granted, the State board of health of New Jersey, at least, which had fully availed itself of the privilege, had not detected any case of infection traced to the circulation through the mails.

Third Day—Morning Session.

Health Legislation.—The report of the committee on health legislation contained a proposed bill to establish a department of public health, the latter to be under the control and management of a commissioner of public health, who should be a regularly educated physician, appointed by the President of the United States, and whose term of office should be six years.

Surgeon-General George M. Sternberg, of Washington, spoke in regard to the bacillus of yellow fever, with which, in common with Sanarelli, his name is so prominently identified.

Dr. J. E. Monjáras, of San Luis Potosi, Mexico, spoke of the necessity for adopting an international classification of the professions.

Dr. Peter Bryce, of Toronto, read a paper in which he emphasized the view that in dealing with tuberculosis it was the duty of the State to do whatever could be done by the individual.

Consumption as an Indoor Disease.—Dr. Samuel W. Abbott, of Wakefield, Mass., followed with a paper on this subject, saying that no form of infection had been studied with greater interest during the past quarter of a century than that of tuberculosis. As proofs that consumption was an indoor disease, he first called attention to the evidence shown by occupations, and secondly, to evidence presented by the conditions of age and sex.

At the close of the morning session the members visited the Medico-Chirurgical College and Hospital of Philadelphia, where they were entertained at a luncheon, and were afforded an opportunity of inspecting the splendid new amphitheatre and the various appointments of the institution.

Third Day—Afternoon Session.

Urgent Need of Sanatoria for the Consumptive Poor of Large Cities.—Dr. S. A. Knopf, of New York, opened this session with the reading of this paper. The question what to do with the thousands of tuberculous patients who inhabited the tenement districts of our large cities, unconsciously disseminating the germs of their diseases among their own kin, friends, and neighbors, or who crowded the wards of our general hospital to the detriment and danger of the patients suffering from acute diseases, had become for the sanitarian one of the vital issues of the day. A number of well-known sanitarians were quoted as expressing the belief that the only solution of the question was the erection of special sanatoriums under municipal control. Two other papers were read on the subject of consumption. One dealt with bovine tuberculosis in its relation to the public health, and the other with tuberculosis and milk supply.

Dr. Lawrence L. Flick, of Philadelphia, in discussing the papers, said that no hope of accomplishing great results could be looked for until the public was educated on the subject of the infectiousness of the disease. This education was going on, and in Philadelphia in the last ten years there had been a reduction of the disease by one-third.

Dr. Lydia Rabinowitsch, of Philadelphia, told of the experiments which she had made in the past two years with butter and milk. In milk she had found from twenty to thirty per cent. of tubercle bacilli. In eighteen samples of butter from different stores she had not found the bacillus of tuberculosis, but had found a micro-organism which very much resembled it.

Dr. E. F. Stewart, of East Orange, N. J., presented a paper entitled "A Plan for Purifying Water."

Investigations of Water Supply by the United States Geological Survey.—Mr. F. H. Newell, of Washington, D. C., followed with a paper in which he said it had been demonstrated again and again that purification of sewage by filtration or by irrigation was practicable and could be conducted at reasonable expenditure, and it was to be hoped that the time was rapidly approaching when public sentiment would be aroused to the degree of compelling such filtration whenever public health or comfort was imperilled.

A Brief Review of the Work of Sand Filters at Lawrence, Mass.—This was read by H. W. Clark, chemist in charge of the Lawrence Experiment Station. In 1887 the deaths from typhoid fever at Lawrence were 12 per 10,000; in 1889, 18.75; in 1890, 13.33; in 1891, 12.20, and in 1892, 11.11. During 1893 the filter was built, and hence during a portion of the year filtered water was being used. In 1894 filtered water was in use during the entire year, and the death rate from typhoid fever was 5 per 10,000; during 1895 it was 3.07; during 1869, 1.86; and the rate for the present year promised to be exactly the same as for 1896.

Fourth Day—Morning Session.

The report of the committee on disposal of garbage and refuse was read by Mr. Rudolph Hering, C.E., of New York. The report stated that it was inexpedient to make original researches, and the work of the committee had been confined to the collection of statistics and the inspection of plants.

Then followed a report of the committee on the transportation and disposal of the dead, which was read by Dr. Charles O. Probst, of Ohio. Among other things this report favored the preparation of bodies for shipment by licensed embalmers.

Dr. Henry Mitchell, of Asbury Park, objected to this on the ground that it sought to create a special class of workers, to whom all the business would be restricted.

Several other papers were read and discussed.

The following officers were elected for the ensuing year: *President*, Dr. Charles A. Lindsley, of New Haven, Conn; *First Vice-President*, Dr. Benjamin Lee, of Philadelphia; *Second Vice-President*, Dr. John

C. Schrader, of Iowa City, Ia.; *Secretary*, Dr. Charles O. Probst, of Columbus, Ohio; *Treasurer*, Dr. Henry D. Holton, of Brattleboro, Vt.

The association will hold its next meeting in Ottawa, Canada, 1898.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 13, 1897.

T. Mitchell Prudden, M.D., in the Chair.

Large Aneurism of the Middle Cerebral Artery.—Dr. George P. Biggs presented an aneurism of the middle cerebral artery, of unusual size. It had been taken from a male, sixty-five years of age, a watchman by occupation. He was found sitting in a chair, leaning far over to the left side, the left arm hanging helpless. He talked with great difficulty, and stated that the attack had begun with a very marked vertigo. He had succeeded in reaching a chair before falling. Soon after he was discovered he became speechless. The breathing was very slow and irregular, and the face was flushed. Both pupils were contracted, the right one slightly more than the left. The pulse was 64 and regular. The radial arteries were hardened. The urine had a specific gravity of 1.013, and contained a trace of albumin but no casts. The paralysis of the left side gradually increased and extended to the left leg. He became comatose, and died on the second day after his admission to the Hudson Street Hospital. The clinical diagnosis was cerebral hemorrhage.

On autopsy, aside from the lesions inside of the cranium, there were marked congestion and œdema of the lungs, and quite advanced chronic diffuse nephritis. The skull being opened, the dura was found to be extremely tense. There was a thin subdural clot over the base and over the lower part of the outer surface of the right hemisphere of the cerebrum—in other words, a moderate amount of subdural hemorrhage. There was a marked prominence of the middle portion of the right hemisphere. Beneath the pia over the right side, especially over the region of the right Sylvian fissure and over the base of the brain and the temporo-sphenoidal lobe, there was a very extensive hemorrhage. The ventricles were empty. The right hemisphere being cut into, a very large hemorrhage was found just outside of the lateral ventricle. It measured about 7 cm. antero-posteriorly, 5 cm. vertically, and 5 cm. transversely. At first this appeared to be an ordinary cerebral hemorrhage, which had apparently broken externally, the hemorrhage having taken place first in large amount beneath the pia, and then broken out, producing the subdural clot. There was, however, a very decided hardness of the middle cerebral artery in this fissure. This was taken out, the clot carefully removed, and the aneurismal sac dissected out. This aneurism measured 1 cm. in length and 0.75 cm. in diameter, and was ovoid in shape. There was a large ragged tear on the superior surface, through which the hemorrhage had occurred. The aneurism was located in the middle cerebral, about 1.5 cm. from the origin of the vessels.

The points of interest in the case were the unusual size of the aneurism—larger than any that the speaker had previously seen upon a cerebral vessel—and the fact that on first examination it had so closely resembled an ordinary cerebral hemorrhage.

Tubercle Bacilli Found in the Fæces.—Dr. George Biggs also presented microscopical specimens from a case of ordinary pulmonary tuberculosis of several months' standing, in which the attending physician had found tubercle bacilli some time before. In the past month the patient had developed a diarrhœa, which had been clinically diagnosticated as due to tuberculous involvement of the intestine. The patient being very anxious about it, it was suggested that an examination of the stools should be made for tubercle bacilli. The examination showed the presence of a distinct mass of purulent matter, and its nature had been verified under the microscope. When it was stained, several tubercle bacilli were revealed. The idea of making such an examination had at first seemed to him ridiculous, but it was interesting to note that the search had been successful. It might be assumed by some that the mass was really a mass of sputum that had been swallowed.

Malarial Parasite of the Quartan Type.—Dr. Henry Heiman exhibited under the microscope the quartan parasite, obtained from a patient in Little Rock at his request. He had been very anxious to find the quartan parasite, but had never been able to do so in specimens secured in New York City. The specimen presented exhibited a parasite such as he had never seen before, and the clinical history indicated the quartan type of malaria. The patient was a boy of eleven years, who had suffered from malaria for a year or two. At first the malaria had assumed the quartan type, but later on the boy had had chills every second day or even every day. This might be accounted for by supposing that he had had several infections of the quartan parasite. In this parasite the red cell was not swollen. The pigment was located more in the periphery of the organism, but the organism itself appeared smaller. As it was believed that the spores were the most characteristic and distinguishing feature, it was unfortunate that they were not found in this specimen. In the tertian, seventeen to twenty spores were supposed to be in one parasite; and in the quartan, from six to seven of these spores. He had been unable to confirm the statement that the pigment was coarser in the quartan.

Adeno-Myomata of the Uterus.—Dr. T. Mitchell Prudden presented microscope slides. He said that a considerable number of cases had been reported in late years of uterine myomata, or fibro-myomata, in which glands of the uterine type were present, sometimes with cysts. These myomata might be either subserous, intraparietal, or submucous. They were sometimes directly connected with, and the gland structures were evidently derived from, the uterine mucous membrane. But they were often so distant and so entirely separated from the mucous membrane as to justify the conjecture that they were derived from some embryonal abnormality associated with the development of the Wolffian body. These tumors had formed the subject of a monograph by Recklinghausen, and had been discussed, with a description of new cases, by Cullen, in volume vi. of the Johns Hopkins Hospital Reports.

Dr. Prudden brought for demonstration slides from two hitherto undescribed cases. In neither of these cases was there anything especially noteworthy in the clinical history. One was from a private patient, thirty-four years of age, whose uterus had been removed on account of a tumor, about 3 by 2 cm. in diameter, in the posterior wall of the cervix uteri. The other tumor was a polypoid growth, about the size of a hen's egg, attached to the posterior wall of the uterus, discovered at the autopsy on a woman of seventy-five, who had died without definite clinical diagnosis, and who was found to have had chronic diffuse nephritis, chronic interstitial hepatitis, and carcinoma of the left ovary. In both cases a series of sections had been made, with a view of discovering some connection between the glandular elements of the myomata and the uterine mucous membrane, but without success. It would be seen that the bulk of the tumors consisted

largely of fibrous and smooth muscle tissue, the former preponderating. This mass was moderately dense and moderately vascular. Scattered irregularly and on the whole sparsely through this fibrous and muscle mass were small collections of gland-like structures resembling islets of uterine mucous membrane. The glands were follicular in type, were lined with cuboidal and low cylindrical epithelium, and resembled those of the mucous membrane of the body of the uterus. Some of the gland lumina were distended with granular material to form minute cysts lined with flattened epithelium. Between and surrounding these glands there was a very cellular stroma, resembling that of the mucosa of the uterine body, and merging gradually into the surrounding fibrous tissue.

These specimens were presented, Dr. Prudden said, not because these tumors were very uncommon, but because they were not usually recognized, and as a contribution to the statistical data of this interesting growth.

The society then adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 4, 1897.

EDWARD G. JANEWAY, M.D., PRESIDENT.

THE meeting was in charge of the section on genito-urinary surgery.

Sterilization of Urethral Instruments.—DR. EDWARD MARTIN, of Philadelphia, read a paper with this title. It was limited to a consideration of the method by which catheters could be rendered surgically clean, as metal instruments were easily sterilized by flaming and boiling. Sterilization immediately before use, the author said, was often impracticable, and when the catheter was required the conditions were usually peculiarly favorable to infection. The ideal conditions for catheterization would be a clean, supple, well-lubricated instrument of appropriate calibre, passed by sterile hands through a sterile urethra into a normal bladder. In the first place, the instrument should be so constructed as to be free from blind pockets for the collection of filth. The most dangerous part of the ordinary catheter was the blind space beyond the eye; hence only catheters provided with a solid head should be used. The internal surface of the catheter was rarely even approximately smooth, and for this reason the difficulty of sterilizing the interior was enormously increased. It was worthy of note that the soft-rubber catheters were the smoothest. The mechanical cleansing of a catheter was best accomplished by warm soapsuds injected into the catheter immediately after use. After soaking, the instrument should be washed in freshly boiled water; the water within the instrument was then "swung" out, and the catheter placed in an oven for a few minutes to dry. All soft instruments stood well this process of mechanical cleansing. Sterilization might be accomplished with heat or with germicidal drugs. Dry heat had been tried by him, but it had hopelessly ruined the catheters, and the same was true of steam. Boiling, however, acted more satisfactorily, and if not continued for more than five minutes the better-grade catheters were not injured and were rendered sterile. The cheaper catheters were damaged by such boiling, but the rubber instruments seemed rather to be improved by it. This process of sterilization was adapted to the needs of the layman, and the catheter could be stored in a sterile cloth. Alcohol and carbolic acid quickly destroyed the finish of a catheter. Any gum catheter would lose its lustre, even if soaked in alcohol for only one minute. Antiseptic soaps had seemed to open up a very promising field, but his experiments had shown them to be entirely useless. Another easy method of sterilization was that by the vapor of mercury. The washed catheters were placed in a closed compartment containing metallic mercury, either exposed in a shallow tray or in a finely divided state in a flannel. An exposure in this way for fourteen hours, it was claimed, would completely sterilize the catheters. However, his experiments and those of others had shown that reliable sterilization could not be obtained unless the exposure was about five times as long. A convenient and efficient method of sterilization was by the use of a tight box with shelves for the catheters and a compartment containing paraform powder. Culture experiments had proved the method to be exceedingly satisfactory, but an exposure of eighteen hours was insufficient, and in the case of instruments of fine calibre the results were unsatisfactory even after twenty-four hours. Even unwashed catheters of moderate calibre were rendered absolutely sterile by an exposure of forty-eight hours in the paraform box. The method was simple and reliable, and provided for the aseptic storage of the instruments. The vapor was found to be slightly irritating to the mucous membrane of the urethra when the instruments were used. The formaldehyde process had been found completely satisfactory for the sterilization of the instruments of fine calibre, such as ureteral catheters. The vapor should be passed directly through the catheters. The formaldehyde was conveniently kept in a tube under pressure, and by unscrewing a cap the vapor could be injected in a concentrated form into the catheter. A few seconds had been found amply sufficient to sterilize the interior of even the fine catheters. It should not be forgotten that the lubrication and the introduction of a catheter were often the means of causing infection. It was a good plan for the operator to wear sterile cotton gloves, changing them for each case. The penis having been passed through a hole in a sterile towel, the meatus should be syringed out with salt solution.

The Best Lubricant.—The lubricant was best kept in a narrow jar deep enough to allow of the introduction of the catheter to a depth of eight inches—for example, a specimen jar. Investigation had failed to discover a thoroughly satisfactory aseptic lubricant. The best were albolene and a twenty-three-per-cent. solution of boroglyceride. The former made it more difficult to clean the instrument; the latter was a mild antiseptic, decidedly inhibitory, and an excellent lubricant, although not so good as the albolene. Argonin, in the strength of 1 to 1,000, had been experimented with, and had been found to cause but slight irritation. By flushing out the urethra during catheterization, the danger of infecting the bladder could be greatly lessened, but there was a distinct danger incident to the use of all irritating disinfectants—*i.e.*, they were liable to set up a total urethritis which would strongly predispose to infection. The sterile catheter should be introduced while sterile salt solution was flowing through it. In cases of long-standing disease of the bladder, he adopted this method and entirely omitted the lubricant, thereby diminishing the risks of infection.

Self-Catheterism.—Patients who were compelled to practise self-catheterism should be furnished with soft-rubber catheters of a size and shape of tip which would permit the easiest and least painful entrance into the bladder. It would usually be found that the soft-rubber coudée catheters fulfilled these requirements. Even the most supple woven catheter would be found rigid for half an inch of its length, when compared with the soft-rubber instrument. The rubber coudée catheters had proved far more satisfactory than any others that he had used in practice. These

catheters were not only easy to pass, but were cheap and were readily made sterile. The patient should provide twice as many catheters as were needed for use in the twenty-four hours. After boiling the number required for one day, they should be wrapped up in a sterile fabric. He had had constructed a bamboo cane, in one end of which was a small cylindrical paraform box containing four catheters, and in the other end another case for the soiled catheters and for the lubricant.

Clinical Results More Reliable than Laboratory Reports. — Dr. Samuel Alexander said that he agreed substantially with all that had been stated in the paper; nevertheless as a clinician he felt that many of the ideas there presented must be characterized as Utopian. It was a very much simpler matter to carry on a system of thoroughly sterile catheterism in hospital than in private practice. In his service at Bellevue Hospital a large number of methods had been tried, and these had been simplified as much as possible. The best grade of catheters had been selected, but he was not yet prepared to give up the woven catheter, although admitting that it was most difficult to sterilize. For a time he had had the catheter washed in soapsuds, then injected with a five-percent. solution of nitrate of silver, followed by a solution of chloride of sodium, and afterward dried and put away. The method was exceedingly dirty and stained the hands very badly; moreover, the culture experiments had not been so satisfactory with this method as had been anticipated. In general, he would say that the clinical results had been very much better than one would have expected from the laboratory reports, and he would very much prefer to trust to his clinical observations than to the laboratory reports of what his results ought to be. Another method had been to throw the catheters into a basin of boiling water immediately after use. They were then collected and washed with soapsuds, and those that could be boiled were treated in that way. He had not found that boiling for five or ten minutes would fulfil the laboratory requirements. Last summer he had used a Janet sterilizer in his office, in connection with formaldehyde, but had found that a much longer time was required to effect sterilization than had been stated, if the catheters were old ones. Another objection was that a catheter must be washed before use, otherwise much stinging pain would be caused by the gas clinging to the outside of the catheter. If this was done with water that was not absolutely sterile, the whole process would be vitiated. Catheters that could not be boiled were immersed in very hot water, after being thoroughly cleansed with soap and water. He could in this way get as good results as by using the catheters sterilized by formaldehyde.

Just as Good Results without Irrigation.—At one time he had advocated and practised the plan of sterilizing the urethra, but he found now that he got just as good results when he did not wash out the urethra as when he washed it out before introducing instruments. For this reason he did not now wash out the urethra before the introduction of the catheter, unless a severe urethritis was present. A good deal depended upon cleansing the meatus, yet simply washing off the meatus was sufficient in an ordinarily clean person. He believed firmly that although one had absolutely sterilized the catheters, if one did not use the instruments with proper skill and dexterity, the amount of trauma so produced would be an active agent in carrying infection from the urethra into the bladder.

The Essentials for Aseptic Catheterism.—Three factors were essential for aseptic catheterism, viz.: (1) as clean a catheter as possible; (2) the gentle use of it; and (3) the catheter must be of the best grade—not only smooth, but sufficiently flexible. New catheters were likely to be too stiff for proper use; they should accordingly be frequently soaked in hot water at first, and drawn through the hands in order to render them sufficiently supple.

Catheter Life. — The method advocated by the reader of the paper for those prostatics who had to catheterize themselves was a good one, yet it was not probable that it could be carried out in very many instances. In the beginning of catheter life, when there was residual urine with obstruction and when the urine was clear, no pains should be spared by the surgeon to have the catheters absolutely sterile and to see that the catheterism was performed at absolutely regular intervals. A person with an enlarged prostate at the beginning of catheter life could be passed through what used to be the dangerous period of catheter fever without any noteworthy infection of the bladder. But the time would come when that patient did not require such careful watching, when the bladder was not congested, and had ceased to be a fertile field for the growth of micro-organisms. Then the absolute and rigid rules for catheter sterilization were not so important as at the beginning of catheter life.

Individual Vulnerability.—Dr. Willy Meyer said that many were inclined to wonder at the number of catheterizations daily performed without any serious reaction and without the precautions advocated being taken. There were certainly great individual differences, and bad results occasionally followed even when unusual care had been taken in the catheterism. It was evident that the virulence of the organisms and the condition of the patient's system at the time exercised a potent influence. It should be emphasized, for the benefit of the general practitioner, that metal and rubber instruments could be sterilized by washing and boiling in water for five minutes.

Prefers Chloride of Calcium and Formalin for Sterilization.—His own practice had led him to believe that the best method of sterilization for gum-elastic catheters was by the use of formalin. The instrument could be dried by the aid of chloride of calcium, and then could be placed in a suitable receptacle and exposed to the formalin. The use of the chloride of calcium he believed to be an important point. In spite of the greatest care in sterilizing the instruments and the urethra, urethral fever was bound to occur in a certain number of cases. It was probably due to infection with the colon bacilli in connection with traumatism. He had observed this occasionally in his first efforts at cystoscopy. Nitze had devised a special sterilizer for steaming the cystoscope, but in the speaker's hands its use had resulted in seriously damaging several cystoscopes. It had been found that formalin vapor did not attack the cystoscope; hence it was now possible safely and efficiently to sterilize such instruments. Since he had adopted the plan of flushing out the bladder repeatedly after the first passage of instruments in patients suffering from prostatic enlargement, he had not observed urethral fevers. As the ureteral catheters could now be properly sterilized, it was perfectly justifiable to use these instruments, but one should be satisfied at first with passing the instrument only a short distance into the ureters.

The Flora of the Urethra.—Dr. Robert W. Taylor said that he was afraid that the elaborate method advocated in the paper was not practicable in most instances; moreover, he was of the opinion that fully as good results could be obtained by the well-known clinical methods outlined by Dr. Alexander. It had been clearly shown that a very common inhabitant of the meatus and its vicinity was the colon bacillus. The first inch of the urethra contained more microbes than any other part, except the bulb. Several good observers insisted that the gonococcus was, under nor-

mal conditions, a harmless denizen of the urethra, and that the changes in the tissues incident to traumatism, as produced by sexual indulgence, the passage of instruments, and changes in the urethra from prostatic disease, rendered this micro-organism noxious. It was true that this was still a mooted point, but it was well worthy of thoughtful consideration. The speaker recalled one case of what the patient called "acute clap," which had originated from the overzealous use of the endoscope by a surgeon. Dr. Prudden had found in the cultures from this case the micrococcus ureæ—a micro-organism that had hitherto been considered harmless. He believed there were many saprophytes in the urethra which were usually innocuous, but which became hostile under altered conditions of the mucous membrane. Many a physician was accused of having infected a urethra with germs from without, when he had really done it by the use of too large instruments or by bungling manipulations. It should always be remembered that a man carried around within himself the agents of infection in the urethral canal and perhaps also in the bladder.

The Method Must be Simple. — Dr. L. Bolton Bangs said that in considering the relation of infection to an individual patient he had been led to observe that in order to have the physician's directions obeyed, particularly in the prostatic cases, these directions must be as simple as possible. There was no exception to this rule, not even when medical men were the patients. Most men were willing to wash their catheters with hot soap and water, and perhaps even to boil them, but he had not been satisfied with the results obtained in this way. He had been experimenting with simple methods of sterilizing catheters by the use of formaldehyde, but this investigation had not yet been completed. We should always bear in mind that there was a certain individual vulnerability to infection. He had known the most careless and dirty men to live to good old age without the urine having been rendered more than slightly turbid in spite of the long and constant use of the catheter.

The Metallic Catheter Responsible for Much Infection.—Dr. Alexander J. C. Skene said that, while he recognized the value of the sterilization of instruments, he was sure that too much stress had been laid upon it, and that quite a number of surgical sins were committed in the name of sterilization and aseptic surgery. He recalled the fact that cystitis had been very common in cases of catheterism before the advent of antiseptic surgery, and his disappointment on finding that the number of cases remained undiminished, even after antiseptic surgery had come in vogue, just so long as the old-fashioned metallic catheter was employed. These instruments had been largely responsible, whether they were clean or filthy, for these cases of infection, for as soon as they had been abandoned the cases of cystitis from catheter infection had been lessened fully fifty per cent. Of course, the surgeon should be exceedingly careful about having the hands and the instruments clean, and this was not difficult of accomplishment in practice. He had found that if a cystoscope or an endoscope were exposed in the operating-room to the formaldehyde vapor, it would be clean enough for use, and he had never seen any harm from the employment of these instruments when so treated. It was necessary only thoroughly to boil the Jacques soft-rubber catheter for fifteen or twenty minutes to secure thorough sterilization. After having been sterilized in this way the catheter should be put in a sterilized tube, and the ends closed hermetically or with rubber caps. When it was necessary to carry around such instruments, they should be washed out with ether vapor and then immersed in a twenty-per-cent. carbolic-acid solution just before use. He used the same method when the cystoscope or endoscope had been kept for a considerable time after having been sterilized in the manner already described, and he was perfectly confident from clinical observation that such treatment effectually put the noxious germs to sleep. The great difficulty he had found was in properly cleansing the urethra and also the mouths of the ureters.

The After-Cleansing of the Urethra. — It had always seemed to him somewhat pathetic to see a surgeon take infinite pains in sterilizing the catheter and then pass it in through a canal teeming with germs of all kinds. It was his practice to fill the urethra with some sterilizing solution, and allow it to remain there for some time before the passage of the instrument. In catheterizing the ureters he had always taken the pains to sponge off the mouths of the ureters after having flushed out the urethra and bladder. An additional precaution was to flush out these parts with some sterile solution after the necessary manipulations had been carried out. Such procedures, he was confident, would do more to prevent and control infection than the more elaborate methods directed entirely to the sterilization of the instruments. He knew of no germs, except possibly the tubercle bacilli and the gonococci, that would do any harm if they remained for a short time in a bladder that was entirely free from abrasion.

Dr. Frederic R. Sturgis said that the main point was cleanliness, and that was, after all, what was meant in practice by the term "sterilization." When the discharge was confined to the deeper portions of the canal, the first effort should be to determine its nature and that of the germs there present.

Urethral Irrigation Important.—Because we were not able absolutely to sterilize the urethra was no reason why we should not carry out irrigation of the urethra. One of the best means of accomplishing this was to have the patient urinate. Failing that, irrigation might be employed either by means of a double catheter or by filling the urethra with a weak solution of permanganate of zinc or of argonin, by means of a fountain syringe. In the majority of instances irrigation of the urethra, he believed, was unnecessary, and under all circumstances it was impossible thoroughly to sterilize the canal. As a lubricant he used borated solution of glycerin or a borated solution of oil. The oil was first sterilized by dry heat, and then as much boric acid was added as the oil would take up. Small portions of this lubricant were kept in a tube stoppered with cotton, and at the conclusion of the day's work the remaining portion was thrown away.

Traumatism Strongly Predisposes to Infection. —Dr. Eugene Fuller said that the sterilization of urethral instruments was still in its infancy. It was a matter of much importance, but in its consideration we should not overlook the large part played by traumatism in the production of infection. This had been well illustrated by one of the speakers, who had stated that the number of infections had been reduced fifty per cent. by abandoning the metal instrument, which was only another way of saying that traumatism had been responsible for much of the infection. It seemed to him that if the genital apparatus were perfectly healthy—if there were no seminal vesiculitis—it would be very rare for that tract to be infected by an instrument, unless the latter was very large or traumatism was produced. Traumatism of the deep urethra was a very common cause of infection. Every one was familiar with those occasional cases of epididymitis developing even after all the usual precautions had been taken to sterilize the parts. The secret was often to be found in the fact that the instrument had been forced through an obstructed deep urethra. Such an accident, from distention of the deep urethra, could be guarded against by previously ascertaining the condi-

tion of these parts by a digital examination through the rectum. There was comparatively little danger of infecting the prostate itself; the capsule was often tumefied and inflamed, but the focus of infection was primarily in the ejaculatory ducts. Tuberculosis was extremely likely to get a foothold at the prostatic sinus.

Gentle Manipulations and Urethral Irrigation Essential.—Dr. E. L. Keyes said that every one, from the practical side, paid less attention to the antisepsis of the instruments than to other factors, and this seemed to him just. We did not usually interfere by the introduction of instruments into the urethra until the pool had already been defiled. The avoidance of traumatism and the irrigation of the urethra after instrumentation were the two most important elements. He returned always with fondness and affection to hot water and ordinary cleanliness, but occasionally diverged to silver, bichloride, or salicylic acid. He should probably continue to depend upon these elements until he was "gathered in." His results had been sufficiently satisfactory to make him feel that it was not necessary to place too much reliance upon asepsis, although the work done in this field was a commendable one and would have a good effect upon the profession at large. It was his practice to irrigate with weak solutions of salicylic acid or 1 to 4,000 solution of nitrate of silver, particularly along the urethra and in the bladder, after instrumentation. This washing out the pool after it had been stirred up by the surgeon was a point in the technique which seemed to him more important even than the early cleanliness.

Dr. Ramon Guitéras spoke of the importance of using only catheters of the best grade. The best ones were covered with lacquer, both externally and internally; the second-grade were only covered externally; and the third or poorest were simply dipped into the lacquer, thus leaving numerous small crevices which made it almost impossible to sterilize the instrument. His own practice was to scrub and flush out the catheter immediately after use, then to boil it for five minutes, then to dry and store in closed glass tubes.

Dr. Ferdinand C. Valentine exhibited an apparatus for sterilizing the cystoscope, in which this instrument could be exposed to a temperature of 240° C. without injury. It was his rule to employ irrigations of the urethra and bladder after the slightest instrumentation; he could not see how irrigation before the introduction of the instrument would be of any service whatever. He asserted his belief that it was in consequence of this routine irrigation that he had not had a single case of catheter fever for the past three years.

A Deadly Heirloom.—Dr. Martin, in closing the discussion, said that his purpose in presenting the paper had been, not to complicate the method of sterilization, as the speakers seemed to think, but to simplify it. The danger of using the metallic catheter had been forcibly impressed upon him by an incident in his hospital service. A physician from the South who was suffering from retention of urine was violently opposed to having a metallic catheter passed upon him, and when he was finally convinced that this must be done he made his will and prepared for the worst. To his astonishment he survived the ordeal, and then explained that in his family there had been a "hereditary" silver catheter, that had descended from his grandfather, and that, according to the traditions of his family, every one upon whom that catheter had been passed had died within two months.

Typhoid.—I believe the Woodbridge treatment of typhoid fever as a specific is a delusion.—Hugh F. Lorimer.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE TYPHOID EPIDEMIC—HOSPITAL REFORM—OBSTETRICAL SOCIETY—COLLEGES OF PHYSICIANS AND SURGEONS—GUILD OF ST. LUKE—MEDICAL COUNCIL—PROFESSOR STOCKMAN—JUBILEE MEDALS—INEBRIETY—DEATHS OF SURGEON-GENERAL CORNISH AND MR. O'GRADY.

London, October 22, 1897.

The epidemic at Maidstone is still prevalent and causes great public anxiety. It is also the chief topic of conversation when doctors meet. It will perhaps prove the most disastrous epidemic we have seen. There was a fall in the number of fresh cases at the end of last week; on Monday last they declined to 4, on Tuesday to 6, but on Wednesday they rose again to 18. Yesterday there were 14, raising the total from the beginning to 1,715 with 106 deaths. The medical officer's report shows up to Wednesday a weekly average of 12.2 cases per diem as against 26.4, 69.4, and 74.4 for the three preceding weeks respectively. Many are encouraged to hope that this shows the danger is subsiding, but an examination of the daily figures gives rise to doubts. The number of young lives sacrificed is large, about half the deaths having been of patients between the age of five and sixteen. About one-third of the six thousand houses in the town are without proper water supply for the closets. This and other sanitary defects the corporation is determined to remedy as rapidly as possible.

The polluted water pipes were disinfected between Saturday and Monday under the direction of Dr. Sims Woodhead, several tons of chloride of lime being dissolved and the solution passed into the pipes. Why so simple a plan could not have been tried three weeks earlier is as great a mystery as why the water was not cut off at first. The only reason appears to be that the water company did not like the expense. The deaths of more than one hundred persons and the terrible sufferings of the others seem to have had no effect on the monopolists, except as producing a fear for their dividends. The public is indignant, but at present pity is the chief feeling. The judgment of the monopolists is yet to come. The local government board has consented to hold a public inquiry as soon as it will not interfere with the work of attending to the immediate needs of the sufferers.

The Hospital Reform Association held a conference yesterday at which they had secured the Earl of Stamford as president. His lordship quoted statistics showing the enormous increase of outpatients, and read a letter from a general practitioner lamenting the want of cohesion in the profession and holding that the position could be commanded by union, just as the workingmen have found that combination alone can make them masters of a situation. Other speakers animadverted strongly on the fact that a very large proportion of these outpatients were not proper objects of charitable relief.

Mr. Timothy Holmes, who has always taken an interest in this question, held that it is not so much a pecuniary as a medical one, the time of the consultant being too much taken up with chronic or trivial cases. But the general practitioner will reply to this only that the consultants could relieve themselves if they would, and in so doing would remedy the abuse.

Sir William Broadbent took a different position, remarking that to get rid of abuses medical men must have power behind them, and this power they had in the Sunday and other funds, but time would be required. This strikes me as very poor support to the cause, for

the Sunday fund has had a fairly long time but has never moved in this or any other way likely to benefit the general practitioner. The managers of the fund have one *bête noire*—the special hospitals: but if they could shut them all up they would gladly transfer all the patients to the overcrowded waiting-rooms of the general hospitals and contribute to enlarging these. How would this benefit the general practitioner or diminish the admitted abuse?

Sir H. Burdett recommended the association to wait until next year to see the result of a new plan of collection and distribution. Then he said many out patients were willing to subscribe and could do so by means of a projected stamp album. This is much like the invitation, "Open your mouth and shut your eyes and see what I will send you." The general practitioners are to wait with open mouths while their patients buy six-penny albums and say they are entitled to the hospital care for which they have paid!

A resolution to appoint a committee was carried, but most of those present refrained from voting—a sad indication on which the reformers may well ponder.

At the Obstetrical Society a paper by Mr. Doran on the management of true and false capsules in ovariotomy gave rise to an interesting discussion. Mr. Doran wrote an article last year on the anatomy of these capsules, in which he referred in reply to an inquiry as to the precise anatomical differences. When a capsule should be cut away, when it should be let fall into the pelvis, and when it should be stitched to the lower end of the wound and drained, were the main points considered. The first plan should be followed if possible when the capsule is healthy, the second when no pedicle can be formed and hemorrhage is under control. Fixation must be employed when there is advanced inflammatory change with suppuration of the tumor, or when hemorrhage is not quite controlled. The question of using iodoform-gauze stuffing evoked some different opinions. Dr. Herbert Spencer had used it with great satisfaction for the last four years, and considered it an excellent means of checking hemorrhage, averting sepsis, and blocking out intestines from torn capsules and infected areas. Dr. Cullingworth (president) said he had not had a large experience with gauze packing. Its removal was a formidable matter and produced so much distress, bodily and mental, that he used it only when compelled. Still he recognized its immense value in certain cases, *e.g.*, in hemorrhage from vessels to which it was impossible to apply a ligature on account of their lying so deep in the pelvis. The subject of iodoform poisoning was also mentioned by some of the speakers.

The Harveian oration was delivered at the College of Physicians on Monday, when a good audience assembled. The orator this year was Sir W. Roberts. At the close the Baly medal was presented to Professor Schäfer; the first Weber-Parker medal and prize were awarded to Dr. Arthur Ransome, and a second medal was given to Dr. Peter Paterson of Glasgow. The Moxon medal was awarded to Sir S. Wilks, the president.

At the meeting of the council of the College of Surgeons thanks were awarded to Mrs. Gowlland for the presentation she had made of the beautiful drawing of her late husband; and Dr. Woodhead reported the results of his recent visit to Germany to compare the methods of preparing diphtheria antitoxin.

The "Guild of St. Luke" should be satisfied with the success of its special service at St. Paul's Cathedral, which was held on Thursday evening, when the archbishop of York preached. In the course of his sermon he said to the assembled doctors: "The most ancient of the guilds were religious institutions, and the medical profession has never been lacking in contribution to religious literature. Yours is a religious calling, though not usually accounted as such."

The Guild of St. Luke is a society of medical men attached to the church—mostly the very "high" church and much given to ritualistic practices. Perhaps from its prepossessions in this direction arose its desire for a great ceremonial in the cathedral. A service was arranged for and graduates were asked to come in their academic robes. A large number did so, and gowns and hoods gave color and brilliancy to a scene such as is seldom met with in church, for the congregation was a large one even for the cathedral.

The majority of Prof. Victor Horsley over Sir W. Foster exceeded eight hundred. The official return of votes recorded is: Mr. Horsley, 6,946; Sir W. Foster, 6,112; Dr. Rigby, 197; Dr. Diver, 81.

The new calendar of the College of Surgeons gives the number of fellows as 1,191 against the members' masses of 17,332. The finances seem to be flourishing.

Dr. Stockman has had a very warm reception at Glasgow as the new professor of materia medica at the university. He delivered his introductory lecture on the 14th, when the principal introduced him, welcoming the bearer of so splendid a reputation, and Professor Gairdner referred to his great qualifications for the chair. The students gave him a good welcome too. In his address he paid a tribute to Professor Charteris, his lamented predecessor. Dr. Stockman's friends in Edinburgh invited him to a dinner before he left and were equally enthusiastic as to his merits.

Dr. Fred. St. George Mivart has been appointed a medical inspector to the local government board in consequence of the lamented decease of Dr. Barry, mentioned in my last. The new government inspector qualified in 1881, took the F.R.C.S. of Edinburgh in 1885, and M.D. at Louvain in 1889.

The jubilee medal has been conferred on Sir William H. Flower, K.C.B., F.R.S., president of the Zoölogical Society, and Dr. Hicks, F.R.S., president of the Geological Society.

Surgeon-Major Poole, M.D., read a paper last week before the society for the study of inebriety, in which much testimony was collected in confirmation of heredity as a chief cause. The president, Dr. Norman Kerr, and several other members repudiated the common remark that "doctor's orders" were mostly to blame. Dr. Kerr said he could trace such influence in not more than one-half of one per cent.

Surgeon-General Cornish, C.I.E., honorary physician to the Queen, died on the 19th inst., aged seventy years.

Mr. E. S. O'Grady died of pneumonia on the 18th. He was the gentleman who was determined to bring the conduct of the managers of the Mercer's Hospital before a court of law and who declined to allow them to confiscate his rights. His courage and uprightness were remarkable, and his skill as a surgeon was acknowledged by all. What will be the effect of his unexpected death on the Mercer's scandal it is too soon to conjecture.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of the Medical Record.

SIR: As a country practitioner I would like to ask the editor or the readers of the MEDICAL RECORD for information regarding the treatment of consumption. Professor Koch discovered the bacillus and has ever since been trying to find something to kill it. Shirley, of Detroit, a few years ago, it will be remembered, tried the inhalation of gas for the same purpose. Not long ago an article appeared in the MEDICAL RECORD detailing a number of patients "cured" by intrabronchial irrigation. One of these patients has just gone

to California to see if there is any help for him in the bland climate of the Pacific slope. We country doctors must of necessity follow the leaders in the large cities. We cannot experiment, but must select the best fruits of investigators in the great medical centres. Now what I would like to know is: Are we working along sensible lines? Are we not pursuing a phantom when we expect to kill the bacillus or wash it away? These leaders tell us that we drink in and inhale bacilli; yet they spend their time "curing" cases by killing the bacilli. The next day perhaps their patient inhales or drinks in a few more; then of course they irrigate or inflate or in some other abstruse way cure the patient some more, and so on *ad infinitum*. Is this common sense? It is a pretty theory and attractive—particularly in these hard times; but is it professional, is it honest? I suppose of course that we all get these bacilli in one way or another into our systems; then why do we not all have tuberculosis? Isn't it reasonable to believe that the reason some of us do not have consumption is because they (the bacilli) do not find in us a suitable soil for their development? If this be true, is it not the most sensible plan to divert our attention from the poor worn-out bacillus to the man himself, and endeavor to place him on such a high plane of health and vigor that this miserable little microbe will fall in the "battle of the cells," and save us the trouble of trying to kill him by shooting at long range with tuberculin or an irrigation tube?

If we can ever succeed in killing the bacillus, will it "cure" the case? I would like to know.

E. W. Bogardus, M.D.

Port Jervis Ridge, N. Y., October 25, 1897.

ANÆSTHESIA AND ITS ADMINISTRATION IN GREAT BRITAIN AND IRELAND, WITH SPECIAL REFERENCE TO ITS BEING MADE A SPECIALTY.

To the Editor of the Medical Record.

Sir: Stimulated by your recent editorial on "Anæsthesia as a Specialty," in order to learn of the ways and means in Great Britain I addressed a series of questions to my esteemed friend, Prof. George Bell Todd, M.B., of Glasgow, and with his permission take the liberty of sending you his valuable communication, feeling certain that it will be of interest to many of your readers. A. Ernest Gallant, M.D.

"**General Remarks.**—Anæsthetists as specialists are not common in our islands; that is to say, specialists in the sense that they engage in that department alone. Still, there are one or two in London and other large English cities who live principally by this calling.

"I cannot give you details as to the exact number of men in Great Britain and Ireland who live by this specialty alone. I should be inclined to put their number at a dozen, at the outside.

"All our chief hospitals here keep an anæsthetist—that is to say, one or more members of the medical staff who by past experience, are regarded by them as capable of administering anæsthetics, and who receive, in alas! too many instances, an honorarium for their work equal to twenty guineas, which is considered by the hospital directors quite enough for such responsible work. In smaller hospitals it is common to give ten or fifteen guineas as a remuneration, and many special hospitals give no remuneration at all. There are two medical men in Glasgow who go in for anæsthesia as a specialty, but they engage in private practice as well. One is the anæsthetist at the Glasgow Royal Infirmary; the other is our new anæsthetist at the Samaritan Hospital. These gentlemen are frequently employed in dental operations at dentists' rooms and at the patients' own residences. In fact, I may mention that so strict are the authorities that no dentist will risk giving chloroform or ether in a big operation without calling in the patient's medical man to give the anæsthetic, or else bring in an anæsthetist. This is certainly the most fruitful source of income for the latter.

"Again, most surgeons in cities employ a young medical man of a few years' standing to give anæsthetics to their private patients. On inquiry one often finds that the young medical man is his chief's assistant in the hospital; not the house surgeon, but the deputy or assistant surgeon, appointed to the surgical wards—more often at the chief's request than at the option of the governors, at least as far as Edinburgh and Glasgow are concerned.

"Sometimes, but not very often, medical students in their fifth year may be taken out by their teachers to administer chloroform; but these men have completed at least two years' hospital training, and probably have given anæsthetics in the hospital under their teacher, his assistant, or the house surgeon.

"I may remark here that female medical practitioners in this country are peculiarly unfitted to give anæsthetics. That such is the case I know from experience, and it is well illustrated at the Woman's Hospital, Euston Road, London, which is remarkable for the failures in administering chloroform correctly.

"As to the ordinary house surgeon, he may be said to be an unknown quantity so far as the giving of an anæsthetic is concerned. Nothing worries a surgeon more than to experience the attempts of a new house surgeon administering an anæsthetic, and also the uncertainty of his success until he has gained the requisite knowledge, when too often the young man is transferred to the medical wards of the hospital, never again to enter the surgical wards unless he has the good fortune to be appointed assistant to his chief, which is about one chance in a hundred.

"A very good plan is that every anæsthetic administration in a hospital is noted in the ward journal, and by whom given, together with any physical signs, pulmonary or cardiac, that have been discovered before the administration took place.

"No student is allowed to administer chloroform in any case before his fourth year, and who has not had two years' hospital experience. He is usually picked out by his teacher from among the other men, owing to his aptness.

"It is often the case that unqualified assistants in private practice administer chloroform and ether very well, but these men have been taught by their employers and have an experience in some cases extending over many years. (They are chiefly 'chronics' and men who have to work in the struggle for existence to keep themselves at their classes; this is common with Scotch unqualified assistants, who are employed by English medical men chiefly in large colliery practices.) But this class is dying out, as the authorities insist on the giving of anæsthetics by qualified men alone, as often crops up at coroners' inquests.

"The newly fledged practitioner is remarkable for his inability to administer an anæsthetic correctly. This is a common complaint among country practitioners.

"So far as the medico-legal aspect of the case is concerned, the anæsthetist must be a qualified registered practitioner. If he is not qualified and registered, he cannot sue for fees in the courts of the land. Otherwise he is regarded in the eye of the law as a quack.

"In order to give you the exact details of the number of anæsthetists at all the hospitals in this country, and the bylaws in force at the various hospitals regulating the administration of anæsthetics, I should require the services of a special commission to visit each hospital and report.

"I have endeavored to give you, I believe, a correct and faithful statement of the case as pertaining to London, Dublin, and Scotch hospitals, and of that of general practitioners here, so that it cannot be said that every Tom, Dick, and Harry has the opportunity or even gets the chance of inflicting a nuisance in the way of giving anæsthetics inefficiently.

"I might close these general remarks by stating that the late Sir George H. B. McLeod was so particular in giving chloroform himself that he commenced the administration in every case, and handed the further work over to his assistant until he himself completed the operation. He had some seventeen thousand administrations with only three deaths, and these took place within the last three years of his life. I merely mention this, as he was my last surgical teacher.

"**I. As to Previous Training and Experience.**—The student gets special lectures from his hospital physicians and surgeons on N_2O, $CHCl_3$, and ether; and combinations, as what is called the A.C.E. mixture here = 1 vol. alcohol, 2 vols. $CHCl_3$, 3 vols. ether—so proportioned, I believe, that they evaporate equally and uniformly at the same temperature and barometric pressure. The student requires to know the use of N_2O and its mode of administration, but nothing can make up for lectures on these modes of anæsthesia except the practical information gained by administration.

"**II. Physical Diagnosis.**—The student is taught to make a searching physical examination of the heart, blood-vessels, lungs, and kidneys as to the presence of organic disease before the patient is proposed to be operated on. If the patient is under observation, it is always the rule to make such an examination a day or two before the proposed administration and not immediately before, as is sometimes done, as it often excites the patient and affects the breathing, etc. Just lately we had a case at the Samaritan Hospital in which pulsation in the suprasternal notch with some increase of dulness at the base of the heart revealed an aneurism of the aortic arch. This escaped the observation of the resident, a lady doctor, till it was pointed out to her.

"The pulse is most important to notice beforehand, as it becomes so altered under chloroform administration. The student is taught to know what a dicrotic pulse is like, so that he may be able to look ahead during the administration of chloroform.

"**III. Urinalysis.**—The presence or absence of albumin is carefully noted; also specific gravity, reaction, etc.

"The presence of sugar in the urine is an indication that if it is necessary to give chloroform the pulse and breathing require particular attention, as often in these cases fatal results follow. This point is strongly impressed on students and medical men also.

"**Inhalers.**—The practice generally followed here is to use an inhaler such as Clover's or Junker's. Quite a number of good inhalers are in the market, and a good anæsthetist will be able to substitute any of them he pleases, or even use the towel or the flannel, or linen-covered cage which acts as a respirator. Our method at the Samaritan Hospital is, say, for merely an examination under chloroform, to give it on a respirator; also for a minor operation; for a major or any operation taking some time, the patient is first put under N_2O, and then kept under ether or chloroform, as the anæsthetist may choose.

"The student is always shown the best apparatus to use; indeed, he must know them as well as any other surgical instruments he may be shown at his examinations.

"**Stimulants** in every case when necessary are given by the orders of the anæsthetist, another medical man administering brandy or whiskey by mouth, or brandy or ether hypodermically, as the case may be.

"Sometimes the patient may get, say, one-half ounce of brandy some little time before being anæsthetized. This is very seldom the case, but it is sometimes given when there is a weak pulse. The general rule is to discourage the use of stimulants unless absolutely necessary. Nitrite of amyl in a broken capsule is sometimes given in threatened collapse, to act as a stimulant to the heart, of course by inhalation.

"Stimulants are always at hand in the operating-room, so as to be ready for instant use if necessary.

"**Means of Resuscitation.**—The artificial methods of respiration are always used. Inversion of the body is strongly recommended before artificial respiration is commenced. Inversion alone has saved a good many patients. The sudden application of a large cloth dipped in boiling water to the cardiac region is useful; a hot towel removed from a steamer has been very useful with us at the Samaritan Hospital. These various acts are performed on instruction by the anæsthetist himself, and not by half a dozen men all shouting at the same time.

"**The Best Anæsthetic and who Decides.**—The anæsthetist states which he purposes to use, and the physician or surgeon usually concurs; at other times he may intend to use chloroform, and finding it unsuitable administer ether.

"**Responsibility.**—The surgeon is not responsible; the anæsthetist is responsible for the patient as long as he is under the anæsthetic. It is agreed that it rests entirely with the anæsthetist.

"**Fees** in private practice are usually handed over to the anæsthetist when the surgeon or physician gets his, unless there is any arrangement for being paid before leaving the patient's house, as sometimes patients prefer to pay the anæsthetist at once.

"**Substitutes.**—With us, usually myself or another member of our staff takes the place of the anæsthetist if he be called away.

"The anæsthetist is required to attend the hospital at the usual hospital hour on all operating-days (with us, 9 A.M., Wednesdays and Saturdays), whether he is needed or not, and at any other time his services are necessary. Of course he knows exactly when to come, as he is on the telephone.

"The anæsthetist rarely asks the interne to do his work; in fact, internes here do not care much about that kind of work.

"The professional standing is good. An anæsthetist usually takes up a specialty like the throat, eye, or gynæcology, or the ear, as he has no time for general practice."

ECONOMY IN HYPODERMIC NEEDLES.

[illegible] M[illegible] R[illegible]

SIR: Thousands of hypodermic-syringe needles are thrown away each year as useless by members of the profession, which could with a slight amount of trouble be restored to their original state. The channel of the needle becomes occluded, owing to the deposition of material derived from the injection fluid. This precipitate is readily dissolved and removed by boiling the needles for a period of ten minutes in a solution of sodium carbonate, which not only cleanses the needle internally, but restores the brightness of the external surface as well.

ADOLPH G. BROWN, M.D.

Key East, N. J.

PUERPERAL SEPTICÆMIA.

SIR: On reading the discussion held by the New York Academy of Medicine, one can but note the difference of opinion entertained by the various members in regard to puerperal septicæmia, its source, and its treatment. Although mine has been somewhat limited, yet I feel that I have had ample experience to justify the following conclusions: that the source of infection is undoubtedly through the uterus, not the vagina; that in a large majority if not in all cases the cause is principally the retention of offending matter *in utero*.

The absorptive power of the vaginal mucous membrane is not great under ordinary conditions. Now, then, this offending matter is one of two things—either secundine or the necessary discharge. This product is by retention so exposed to the abraded portion of the intra-uterine surface that absorption takes place.

All the cases of puerperal septicæmia I have witnessed bear me out in this conclusion, and I think if a proper search is made one will rarely fail to find the cause; and yet the apparent cause is so slight, so inferior to that found in other cases that present no grave symptoms, that we are inclined to infer that systemic conditions have much to do with and are much at fault for this trouble. I have not found septicæmia more prevalent in badly lacerated cases; in fact, my experience has shown quite to the contrary, and convinces my mind that we must look elsewhere than to lacerations of either the uterus or the vagina for a solution of this subject. Just how much is to be attributed to general systemic conditions is a question that to my mind demands a yet closer investigation, and until further evidence has been brought to light on this part of the subject I shall continue to be of the same mind I now am. I have watched these cases closely and earnestly for the past twenty-five years, and I feel that so far we are largely in the dark as to the nature and cause of this dread disease. That thorough cleanliness is a step in the right direction is indisputable. That therapeutical remedies fail in each and every case is also a sad reality. That curettage to a degree that would in the least irritate the endometrium is next to criminal, and anything further than the removal of retained morbid matter from the uterus and its thorough cleansing by the gentlest means is meddlesome and to be condemned. I do not believe ergot has any influence in preventing septic conditions. I rarely give a dose nowadays, and have less trouble than formerly when I believed I had not done my duty until I had given at least one drachm of fluid extract of ergot. I believe that, if we eliminate this "general systemic idea," in thorough cleanliness of the uterus we may safely trust for our success. Proper food, with favorable hygienic surroundings, is next in importance. I am convinced that with a clean uterus we may rest content that nature will do the rest. To obtain this it is not essential that every emptied uterus should be irrigated with any and all kinds of so-called antiseptics. Not at all. In fact, very few need anything of the sort. I rarely irrigate a uterus after delivery at full term; I am more chary regarding one that has attempted to expel its contents prematurely, and on the first unfavorable symptom presenting I rarely fail to wash that organ. One thorough washing is most often sufficient, and I would caution against frequent repetition. Do not repeat your irrigation except as indicated by results obtained, and if this course is followed prudently yet thoroughly by the physician himself you may "to the dogs with your physic."

WILLIAM A. DAVISON, M.D.

[illegible], Mass.

A NATIONAL QUARANTINE SYSTEM.

[illegible], Miss., [illegible]

SIR: Any observant traveller through the South just at this time, when yellow fever is so much in evidence, cannot but become forcibly impressed with the necessity for a quarantine system that is broad and comprehensive in its scope and that can be made to extend beyond the range of small towns, counties, or municipalities. Petty jealousies between rural localities, quarantine regulations widely at variance, and a lack of harmony in the construction and enforcement of quarantine methods have done as much, during the present yellow-fever epidemic in the South, to bring hardship and disaster, as the disease itself.

A recent tour through the South convinces me that this statement is perfectly true. The lack of confidence in local regulations, the harshness with which they conflict with the regulations of adjoining localities, the laxity of methods pursued, are all apparent to the crudest observer. I was informed by many railway officials in the South and by quarantine officers themselves that the attempt, as it is made by the different localities, to prevent the spread of the disease is really doing greater harm than the disease.

All epidemics that assume the scope and magnitude that yellow fever has now assumed in the South are interstate matters always, and matters of vital importance not only in so far as lives are endangered, but in jeopardizing and destroying commerce. The national government has jurisdiction over interstate commerce. Why can it not regulate and preserve the health and comfort of the people, when they stand endangered by so universal and deadly a scourge as yellow fever, and when local measures to restrict its spread are tentative and inefficiently administered?

A national quarantine system or an interstate quarantine system administered by the national government, if done conservatively and efficiently, would give confidence, destroy conflicting regulations between minor communities, and do much to relieve epidemics of the present kind of much of their real harm. Let us have a national quarantine system, and let it exist in fact as well as in name.

WILLIAM P. SPRAGUING, M.D.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 6, 1897:

	Cases.	Deaths.
Tuberculosis	200	111
Typhoid fever	28	9
Scarlet fever	121	7
Cerebro-spinal meningitis	0	3
Measles	189	13
Diphtheria	143	24
Laryngeal diphtheria (croup)	1	3
Chicken-pox	10	0

Eye Complications of Typhoid include, according to C. Stedman Bull, catarrhal conjunctivitis, phlyctenular conjunctivitis and keratitis, loss of accommodation for dilatation by paralysis of the iris sphincter, retinal hemorrhages, paralysis of the external muscles, neuro-retinitis or retrobulbar neuritis, amblyopia, hemianopia, inflammation of the uveal tract, iritis, cyclitis, choroiditis.—*La Méd. WHAT MUST WE DO TO BE SAVED? BEING AN INQUIRY INTO AND A BRIEF SUMMARY OF THE CAUSES LEADING TO THE HOSPITAL AND DISPENSARY ABUSE OF MEDICAL CHARITY.[1]

BY THOMAS J. HILLIS, M.D.,

NEW YORK.

THERE is really after all nothing very startling in the title of this paper; it simply means that the profession of which we are a part is threatened on all sides and beset by many dangers.

It will be my object to-day to point out some of these dangers, and leave the task of applying a remedy for another time, since the few minutes allotted me here admit only a cursory glance at this wide field.

The medical press throughout the country teems with articles on hospital and dispensary abuse, and a wail of distress is heard from one end of the land to the other from the rank and file of our profession. They say that among the causes for this distress and discontent the abuse of charity in hospital and dispensary stands single and alone, conspicuous in its isolation; that these institutions have broken faith with the profession which created them and made their existence possible; that if these abuses are allowed to continue, in a short time a practitioner of medicine will be a rare curiosity outside of a hospital or dispensary; that a profession more ancient than the Golden Fleece or Roman Eagle, and endowed with attributes of mercy and honor, will perish from the earth, and there will remain only the hothouse plants, the clinic and maternity home, founded, fostered, and nourished by a millionaire whose memory is not savory, through the dollars wrung from honest toil and the millions made through syndicates by the maladministration of a government supposed to act for the interests and welfare of the people—a supposition, however; an illusion and a snare.

Before proceeding any farther, it might be well to inquire into the truth or falsity of these charges, so boldly advanced by the profession, against hospital and dispensary.

These concerns are dealing only with conditions that present themselves continually. These conditions are effects, not causes. These effects will be traced to their sources. It will be the purpose of this paper to point out these sources and fasten the responsibility where it belongs. Then there are causes for this hospital and dispensary abuse, and for all the abuses pointed out by the physician in his calendar of persecution and oppression. These causes will be considered, and in the classification of causation the physician himself will have the honor or dishonor of holding high place or being first cause.

This paper will trace an ambitious, unscrupulous young physician, from the moment he leaves the classroom to hang out his sign, proclaiming to the world his calling and inviting that world's approbation and patronage, through years of toil and intrigue, through the ups and downs of a busy, ceaseless activity. It will watch him in his dealings with others, particularly his brother practitioners. It will see if he observes the golden rule, "Do unto others as you would like to be done by," and if the word brother has any meaning, as applied by physicians to each other, and whether it is not hollow and delusive.

By following this physician through the mazes and perplexities, the labyrinths and subterranean channels in which a professional life will run for the first fifteen years of its career, we shall not have much trouble in discovering the principal source from which the river of hospital and dispensary abuse has sprung—namely, the physician himself. Though ages have rolled away since the inspired words were uttered, they still ring through the universe, at once a command, a warning, and a benediction—"Physician, heal thyself."

His Journey in Pursuit of Success.—The young physician, after receiving his diploma, and with the benediction of his alma mater ringing in his ears, starts out into the active practice of his profession. He will not tarry in Jericho until his beard is grown, or immure himself in his cloister until the ink is dry on his diploma. He is charged with medical energy, as a balloon is with vapor or a battery with electric force, and as the exponent of the gospel of healing he sallies forth, a veritable Don Quixote, to heal the sick and bind up the wounds of the injured, though the practical knowledge properly to apply his methods is as crude and visionary and as barren of results as was that of the redoubtable knight to regenerate and reorganize society. He refused to listen to an old physician, as full of knowledge as he was ripe in years, waving him off with a grandiloquent motion of his hand when he offered to point him the way on that memorable morning he started out on his professional career. This stripling out of school, now turning himself loose on society, refused to hear the advice of a sage.

Lord of Himself, a Heritage of Woe.—After some effort he finds a desirable neighborhood in which to locate, and after further effort he secures an appointment on the staff of a free dispensary. He joins a medical society, and the church in the neighborhood; he is now honored as a resident.

The dispensary, while giving him experience which he sadly needs, occasionally supplies a patient whom he can corral to his office by a little deception, quiet entreaty, and tact. In the church he can get at close range to the pastor, and to know the pastor well has a special significance for him, to which assertion many successful physicians can attest. The medical society aids too, by imparting dignity and stability, and, further, it lifts him high above the quack and other vendors of medical wares. Having now secured these three objects so dear to his heart, he has a further ambition; he wishes to become a lecturer, with the ultimate object of blossoming out into a professor. So he hires the lyceum attached to the Sunday school, for a course of lectures on longevity and hygiene, under the auspices of the pastor and board of trustees of the church. To be honest in the matter, he cares not a

[1] Read at the fourteenth annual meeting of the New York State Medical Association, October 12, 1897.

rap about the longevity or hygiene of this particular neighborhood; it would be to his interest were the sanitary conditions to remain bad, and disease, endemic and epidemic, to spread its wings over the people. Unfortunately, he wishes only to exploit himself, and under cover of a lecture, the subject of which he knows little or nothing about, to advertise himself among what may now be called his new constituency. His lecture is commonplace and abounds in catchwords and well-worn phrases, but, as the admission is free, it is heard by the people, who are attracted more by curiosity than by a thirst for knowledge.

In that town where Dr. Youngblood located there were four other physicians; but it will be observed that he did not visit any of them for counsel or advice on such a momentous undertaking as locating and making a start in the practice of his profession. He did, however, visit a livery-stable keeper, and a druggist, and the superintendent of a patent-medicine plant. The liveryman thought there was an opening for a bright young man, especially if he could afford to drive; it would impress his personality the more. The druggist was sure there was an opening, as none of the other four doctors in the town was very well liked; but he asked the physician as a special favor to keep that to himself, as he would not for the world have his name mentioned or in any way mixed up in the matter, since he was only helping a clever young man to make his way in the world. The superintendent of the patent-medicine plant was certain there was room for another physician, and success was already assured if he would only push certain new remedies that his firm was now placing on the market. His signature and photograph would be of great value to them; besides, it would advertise him, it would be a ready avenue to the public ear, and perhaps to the people's heart.

While he was talking to the superintendent, a gentleman stood by, who later said: "The doctors are sleepy in this village; we want a live man, who could easily make a fortune in a very few years." He did not, however, say that he himself was a bankrupt, who defaulted on his obligations, and who was now a fugitive from the vengeance of his creditors.

While talking to the postmaster, Dr. Youngblood fell in with a new acquaintance, who welcomed him to town, spoke highly of his lecture at the lyceum, which he declared he heard with great pleasure; in fact, his wife and oldest daughter were delighted with it, and wished particularly to know when he would deliver his next lecture. In their opinion the last was a masterpiece—plain, forceful, and convincing. He also made mention of the several patients he had sent to him for treatment, as the diagnoses of their cases by the other physicians in the town were doubtful, and the treatment was very unsatisfactory. He added: "We are sadly in need of young blood in this town of ours—and, doctor, what a singular coincidence, your name is Youngblood too. Indeed, how peculiar! A dead streak of luck for you, I assure you."

Dr. Youngblood knew later, but was not now aware, that he was talking to a dead beat, who fleeced the other four physicians in the town for professional services rendered, and who found this gentlemanly means of paying them for the same.

Now Dr. Youngblood felt naturally proud for this mark of respect from his new townsman, also for the kindness he showed him in recommending his friends to his professional care, and invited him to call at his office to see him socially, and, if ever the occasion arose requiring his professional attention, it would be rendered gladly and with good will. This young disciple of Æsculapius, now on the high road to success, did not send any of his professional brothers an invitation to his lectures at the lyceum, but it was observed that one or two bald-headed gentlemen sat in an inconspicuous corner of the lecture hall, and a young lady nudged her escort, exclaiming: "Why, I declare, there are Dr. White, and our old physician, Dr. Black, taking notes of the lecture." Sure enough, the gentlemen were there, to hear what new facts this new physician could impart regarding longevity and hygiene. As before related, they were not invited or consulted in any manner in relation to the lecture or its management; in fact, so far the young lecturer has not seen fit even to ascertain the names of his brother practitioners in the town; he has, however, a well-defined and definite knowledge that they exist. He heard certain names echoing through some sick-rooms where he was called professionally, but these names burned deep into his heart, as they were mentioned with affection and respect, and he made a mental resolution that he would never rest or be satisfied until he downed these patriarchs, whom he regarded as old fogies and only a stumbling-block in the road of progress—indeed, a direct hindrance to the new medical dispensation.

Now Dr. Youngblood cares not a mill for the etiquette of his profession; it has no concern for him. At present he is interested only in himself, and must and will build up his practice, even though the heavens fall and the earth trembles under his feet. Now to accomplish his purpose he will break down all the barriers that have hedged in the traditions of an ancient and honorable calling. He flings etiquette out of the window; later on, after he acquires success, he may amuse himself by observing this etiquette, and perhaps, if pressed hard, accept the presidency of a medical society; at present, however, he is too busy to bother himself with such toys.

In the evening the young physician is consulted by a lady who has contracted a severe cold, which she cannot shake off. She has a cough mixture prescribed by Dr. Goodman six months previous; it helped her then—it has failed now. She did intend to see Dr. Goodman again. He has been the physician of her family for twenty years, has led a blameless life, and is respected by all; but a gentleman of her acquaintance persuaded her to consult Dr. Youngblood, who spoke about a serum in his lecture at the lyceum on Monday night, and said that if this serum was injected under the skin it would quickly destroy the bacilli which were playing tag and having a jollification in the blood current.

"You said at the lyceum lecture that you saw, through your powerful microscope, these little bacilli playing croquet in the lung tissue and having a lawn party on the apex of the right lung of one affected with tuberculosis. These were dreadful things to see, doctor, and if this was told by any other physician in the town we should say he was afflicted with nightmare; but you, coming fresh from a great college, carry the latest, the very latest information, and tell it with an eloquent simplicity that cannot fail to gain for you respect and popularity."

Dr. Youngblood, charmed by the candor and goodwill of this lady, explains that after these pestiferous creatures have been driven out the lung will resume its normal function and the cough cease at once. He makes an artful but superficial examination, and discovers the bacilli lurking within, though he does not communicate this fact to the young lady in words; but his look is fraught with direful forebodings, which he tries to hide by that professional smile, that may mean much or nothing, and is so well known to us all. He gives an injection of his tuberculin; he says another and still another may be necessary, and occasionally the little pests are so well fortified within the house of clay that they cannot be dislodged. However, he is sure that such will not apply to her case, as she has

taken it in time; but as a matter of routine and precaution he gives her a sedative, and enjoins that she shall take a cathartic pill every night and avoid draughts, and dismisses her, after requesting her presence again in two days for further consultation and instruction. At the appointed time she returns with her mother, who thanks the young physician for his successful treatment of her daughter's case. The cough is much less frequent and by no means so hard as it was. "Dr. Youngblood," says the patient, "I believe your serum has accomplished its purpose, and brought death to the miscreants that were gnawing at my vitals; I am happy now, and feel a load off my heart, and regard you as my benefactor."

"Doctor," says the young lady's mother, as she is about to retire with her daughter, "my son was at the Liberal Club on Saturday night, while you gave an exhibition of those wonderful and mysterious *x*-rays, and told so graphically, so lucidly, how you located the bullet in a veteran's heart, which he received while protecting his country's honor and subduing strikers and riot. As it happened, doctor, he was a colonel in the national guard of my own native State, Pennsylvania. As you so graphically and pathetically described, he carried his wound for twenty long years—how he suffered, and what great skill and surgical tact you displayed in locating and removing the cause of his trouble! My son further told how you said you removed a dreadful cancer, by a method new and peculiarly your own, from the walls of the stomach of a lady from India, who came the long journey to have the benefit of the best talent, as the physicians of the Orient had regarded her case as altogether a hopeless one."

Says the lady with emphasis mingled with pride: "My son is an observing young man; he related this story at the whist party we had at our house last night. His father is thinking seriously of making him a physician, and said you would be an excellent preceptor. Before I go, Dr. Youngblood, let me assure you of my good will, and you can count in future on the patronage of my family and of every friend of mine I am able to influence. To be sure, Dr. Goodman has been our medical adviser for twenty or more years. We have esteemed him highly; his successes are entwined in the memory of our house, and his failures we have regarded as the visitations of Heaven; but I declare, doctor, you have captured us completely. My daughter here is in ecstasies over your treatment of her own case."

The young physician's vanity is tickled, and he is justly proud of his success. He tries to hide this pride from Dr. Black, who has not had the pleasure of his acquaintance, as he has not been out much, because of repeated attacks from his old enemy, the gout; but he has heard remarks dropped here and there about the lyceum lecturer and the social confabs at the Liberal Club; but, as might be expected from his age and experience, refrained from criticising the young physician, whose success under legitimate conditions he would be inclined to consider with a kindly feeling, though it leaked out that he did not have a very exalted opinion of the subject matter of the lyceum lectures, or, for that matter, of the lecturer himself.

A Consultation between Physicians.—Now it happens in this wise. Dr. Black is in attendance on a child, sick with a dangerous disease; the case presents grave features. Dr. Black, while retaining the confidence of the family, requests a consultation, and modestly leaves it to themselves to choose who the consultant should be.

On entering the sick-room at ten o'clock next morning, though the hour for consultation was set for 10:15, he is surprised to have the pleasure of meeting Dr. Youngblood, who at the last moment has been summoned over the head of old Dr. White, whom Dr. Black was so sure of meeting in the house of Mrs. Goodyear. After exchanging greetings, Dr. Youngblood says: "Pardon me, Dr. Black, I came a few minutes before the appointed time, thinking you might be here a little earlier yourself. As I am an exceedingly busy man, I must utilize every spare moment of my time." His real reason, however, for coming early is to make an examination on his own account, unhampered by the eye of Dr. Black, and to give and receive some suggestions from the family, in order more thoroughly to familiarize himself with the case, and, if possible, surprise and nonplus Dr. Black at his skill and aptness in diagnosis.

After surveying the room with a pompous air, he asks to see the observation chart, and directs his attention to the nurse rather than to the physician; but as a matter of fact he has already seen this chart on the sly, when he sent the nurse, as a pretext, to communicate some fact to the family in an inner room. He wants to know all about the temperature curve and the pulse wave, now affecting an air of superiority and measuring the sick-room with an insolent stride.

Dr. Black, while a careful observer, does not lay quite so much stress on the variations of these waves and curves. He, however, recognizes that the pulse is rapid and the temperature high; but as the alimentary tract is clear from obstruction and the head comparatively cool, he prefers to direct his attention to the heart and stomach rather than to the temperature. He tells Dr. Youngblood that temperature in a child has not such serious import as in those of more mature years; that to strengthen the heart beat and to have the stomach tolerant of food have always been his first and most important duty. "My professor at college, in whom I have the most implicit confidence," says Dr. Youngblood, "laid great stress on temperature in a child. He declared it acted first on the nerve centres; secondly on the reflexes, which he said were very impressionable and sensitive at this early period of life; and was apt to develop spasm, which so contracted the respiratory group of muscles that it interfered with the return circulation, and was sure to produce cerebral congestion—a grave complication in one suffering from any form of disease."

The gentlemen are agreed on the nature of the disease, but in prognosis and treatment stand wide apart. Dr. Black, while recognizing the gravity of the case, is not absolutely hopeless of the final result; however, since Dr. Youngblood is certain of a favorable termination if his line of treatment is adopted, there is no other course open to Dr. Black but to retire from the case, which he does. This resolution is made by Dr. Black while adjusting his overshoes in an anteroom, after hearing Dr. Youngblood, again on the sly—though spoken in a low whisper—express a desire to be alone in the case to the father of the child, as he was waiting anxiously at the door of the consultation room to hear if the physicians had any good news to convey concerning the outcome of the disease with which his child is now afflicted.

It will be granted Dr. Black's ears are not slow to hear, even if his joints are stiff and he carries a weight of seventy years on his shoulders.

The two physicians part with a cool, self-contained, and quiet reserve, but they do not part as friends—a thing not observed by members of the family, who are worried and buried in grief, and who would be almost inconsolable were it not for the rays of hope kindled in their hearts and the bright light reflected on their path by the favorable prognosis and kind words of Dr. Youngblood.

Dr. Youngblood, now alone in the case, is heroic in his treatment. He blisters, purges, applies the cold pack and ice-bags to the head; he examines the coal

tar series and gives full doses of the very latest antipyretic, also an analgesic and a cerebral sedative, for he has a fear of the reflexes. He, however, succeeds only in robbing the child of the little strength it possessed under Dr. Black's fostering care, for he hourly grows weaker. Next day Dr. Youngblood looks wise and serious; he does not wish the family to understand that he is criticising the methods of Dr. Black, who so recently had charge of the case and in whom they were wont to place such confidence; no, nothing of the kind—oh! no, indeed; but he is extremely sorry he did not have an opportunity to see the child one day earlier, just one day earlier. At present the system is wasted and exhausted, and cannot respond to his new and powerful remedies; even electricity, strychnine, or nitroglycerin is useless now. However, he will try oxygen; it will relieve the paroxysms and make his last hours tranquil and composed.

Next day all is still—only the lamentations of a distressed and sorrowing mother, who between her sobs tells a lady acquaintance who comes to offer her such consolation as is in her power: "Just think, Mrs. Green, my darling could have been saved if we had called Dr. Youngblood earlier—just one day earlier!" Earlier! just one day earlier! was wafted out upon the darkness, and the refrain was taken up by the hills and echoed through the vale—"Earlier! just one day earlier!"—on that memorable summer night when Mrs. Goodyear fell fainting into the arms of her sympathetic friend, Mrs. Green.

While the family is making preparations for the funeral, Dr. Youngblood and Dr. Black meet again. It is only a coincidence, and not expected by either gentleman. The object of each in his visit is different, as were their prognosis and treatment of the now dead child. Dr. Youngblood comes for the purpose of being seen and to advertise himself again. This occasion presents an excellent opportunity, and he is not the man to let an opportunity slip. The fact that he has been acquainted with this family only three days counts for nothing with him. He is sure of a warm reception; they will be grateful for the gallant fight and final effort he has made to save their loved one. Dr. Black comes in obedience to the human impulses that find a home in his breast and a ready outlet in his kindly nature, to offer his sympathies to the family he has known so well for twenty-five years, in this hour of their tribulation. Dr. Black withdraws, but Dr. Youngblood, who is now a conspicuous figure in the house of mourning, remains and chats with the pastor, who himself was a physician, but abandoned that profession for a holier if not a less laborious calling. A theological student is also present, who, feeling himself too much of a sinner to enter holy orders, asks advice of Dr. Youngblood and permission to be accounted as his student, and solicits the honor of calling him preceptor. The divinity student is fearful that there may not be room for another physician in the already crowded ranks of the profession, but Dr. Youngblood allays his apprehensions by assuring him that there is plenty of room at the top for the higher order of talent—a quality he is sure he possesses—and hopes it will not be long after his graduation when he may perhaps climb to the high altitude he himself occupies in his profession and in the public eye. Dr. Youngblood talks on various topics, when finally the conversation turns on the practice of medicine, and the pastor and physician engage in an animated if not learned debate about disease germs in general and micro-organisms in particular—their habits, their haunts, and their influence on the animal economy. Dr. Youngblood declares that all diseases spring from the same source or cause, namely, derangement of adjustment and co-ordination in the vital mechanism. Dr. Youngblood gives it as his opinion that at some time in the future, a period he thinks not remote, the etiology of disease will be thoroughly mastered, and the catalogue of causation from measles to cerebro-spinal meningitis be an open book; a clear bright light will then illuminate the whole domain of medicine; and he hails with acclamation the opening of this new day. The problem of the future, he says, will be, not to cure, but to prevent disease, when the old adage will have a definite if not a new meaning, that "an ounce of prevention is worth a pound of cure." He continues: "The discoveries lately made and the new remedies introduced are passing through a trying ordeal, as have all discoveries and inventions that have gone before—they are receiving, as it were, their baptism of fire; but he has no doubt they will emerge in triumph from the ordeal of flame." The microscope, the chemical equation, and the *x*-rays are leading the vanguard in this era of wonders, and pointing the way to boundless possibilities in the realm of human thought and achievements.

"Dr. Youngblood," says the clergyman, "you astonish me by your familiarity with scientific subjects. I can only say that I am overcome with the magnitude of the situation, and recognize that we are living in a grand and progressive age." After taking a full breath, the clergyman continues: "Dr. Youngblood, if I understand this new gospel, which you have with so much eloquence propounded, the various diseases are but the preponderance of one colony of parasites over another; the leucocytes, always present in the blood, must be ever on the vigil and always prepared to give battle, in order to save the body intact from the ravages of these all-devouring hordes. The leucocytes, then, are at once the scavengers and the guardians of the public health. The blood is the battlefield, and life or death the resultant of these contending forces. Did not the Holy Scripture point out and demonstrate this fact long ago, when it declared, 'The blood is the life'?"

This discourse is heard by many mourners who have come from distant parts to pay their respects to the living and to honor the dead. The pastor will be known for his learning as well as his piety, and Dr. Youngblood's fame for scholarship as well as his rare skill in his profession will be spread far and wide.

Dr. Black, who retired to an adjacent room only to console the bereaved parents, is an unwilling auditor of this ill-timed discussion. Later, on the porch, on his way home, he is approached by the divinity student, who asks the doctor for his opinion as to the relative merits of the discussion between his pastor, Rev. Mr. Mayflower, and Dr. Youngblood, his new preceptor. The old physician draws himself up to his full height and says: "Sir, this occasion is too sad and the time inopportune to answer questions that do not immediately concern the welfare of this afflicted family. I refrain, sir, from commenting on the egotism and bad taste of the gentleman who opened the discussion, or on the gentleman who closed it, for his lack of moral perception and thoughtlessness in desecrating the attributes of his sacred calling."

. . . . . .

Three men are conspicuous figures in a large room, where the town squire holds court, one cold winter's morning in December. There are some whisperings going around in regard to a young woman and an antemortem statement. However, the facts are not clear, and, according to some young lady friends of Dr. Youngblood, it is an outrage to associate his name in any manner with the case. These three men are Dr. Youngblood; his student, Mr. Hopewell, now Dr. Hopewell; and a young man, an accessory to the act, now the central figure in what is very likely to end in a tragedy. This young man takes stealthy but furtive

glances at the ancient squire, while his restless little eyes roam around the courtroom, always to fall when they light on a little old woman in black in a remote corner of the room. She is the mother of the dying girl. There is Dr. Mayflower, reinforced by two deacons and a trustee, a contractor—all have come to attest to Dr. Youngblood's piety and personal worth, and the utter impossibility of either this devout Christian or his talented student, Dr. Hopewell, being guilty of a crime. They have come, if necessary, to give bail in any amount to save these gentlemen the ignominy of entering a cell or spending a night in the lockup.

Dr. Youngblood in Jail. — Dr. Youngblood, in jail, is not wanting in sympathy from without. The sewing-girls from the attics leave their offerings of golden rod and wild daisies at the jailor's lodge, and the more affluent ladies of his now numerous acquaintance bring pressure in the shape of a dollar on the jailor's palm, and are thus able to present Dr. Youngblood personally with an offering of American Beauty roses; and some of his more enthusiastic lady admirers insist on pinning a chrysanthemum on his bosom; some others entwine delicate leaves of smilax in his buttonhole.

A lawyer from Philadelphia, Mr. Sharp, laughs heartily in his office while reading, when he declares the indictment is full of legal blowholes—that it is woven so clumsily and its texture is so loose that a flock of wild turkeys could fly through the apertures or interstices it presents.

It appears it occurred in this way. The district attorney's assistant, who was a physician before he read law and entered the service of the State, was not skilled in drawing up indictments for the criminal calendar. Dr. Youngblood escaped through a technicality. He pleaded, "Not guilty;" but a flaw in the indictment was the thunderbolt, and Mr. Sharp the Ajax who hurled it at the prosecution, though Deacon Primrose, when shaking Dr. Youngblood by the hand, exclaimed, "It was through interposition of Heaven!"

The Founding of a New Dispensary to Commemorate Dr. Youngblood's Escape from Jail.—Now it was said with one voice by the good people of Dr. Youngblood's acquaintance and Rev. Mr. Mayflower's congregation that Dr. Youngblood must have a justification. So they set about at once raising a fund to found another dispensary. A well-to-do old lady, an ex-president of the society of King's Daughters, said she would donate sufficient to build an amphitheatre; that it should be known as the Youngblood Operating-Room of the Free-to-All Dispensary.

Dr. Youngblood, smarting under the disgrace of his late sojourn in jail, almost refused to be comforted, and was quick to discern who were instrumental in this effort to cover him with disgrace. His heart yearned for revenge as the names of Drs. Goodman, White, and Black flitted through his brain. He would accept the honor of being surgeon-in-chief to this new charity only conditionally, and that condition was that the dispensary should be free to all, as its name implied. "Yes," he exclaimed, "as free as salvation or the air we breathe!" He said he was aware that some physicians in the town would prefer that a discrimination should be made, and those able to pay for treatment turned from the door; but such physicians only wanted to draw water to their own mills, and their designs should be frustrated by making the dispensary a "Free-to-All." As this was a free country, the dispensary should be free in fact as well as in name.

Dr. Youngblood was so determined in this resolution that he aroused some opposition among his friends, but it died away after he quoted the lines from a well-known author:

> "Come one, come all! this rock shall fly
> From its firm base as soon as I."

It was a matter of only minor importance to Dr. Youngblood when the Free-to-All Dispensary was sued for malpractice, but the suits were dismissed by Judge Youngman on the ground that the dispensary was a charitable institution and not responsible for the bungling of its surgeons.

The lawyer for the plaintiff, now a helpless cripple because Dr. Youngblood and his assistant, Dr. Hopewell, mistook a fracture at the hip-joint for rheumatism, could not agree with the learned judge: he thought every tub should sit on its own bottom, and that the dispensary should not hide its surgeons under the petticoats of charity, in order to escape an obligation and a responsibility from which a private physician would have to defend himself before a jury of his peers.

It appears that the old gentleman, now a cripple, was on a free excursion—though it was said he had money in the bank—and while promenading the deck of the excursion steamer slipped on an orange peel, and suddenly sat on his right hip. Next day, at the Free-to-All Dispensary where he was carried, Dr. Hopewell said it was a sprain; and as the old man was suffering from rheumatics, Dr. Youngblood paid no attention when the patient said he could not raise his right leg and that he had a severe pain in the region of his groin.

The physicians' incomes were gradually shrinking, as the town was constantly growing poorer and the people were flocking to the Free-to-All Memorial Dispensary. Dr. Youngblood did not mind this, for he had received a windfall from the old lady who founded the Youngblood Operating-Room, now just deceased, for his skill in treatment and fidelity in watching over her during the last hours of a well-spent life.

It may be noted the town grew so poor that another workhouse had to be built and a wing added to the jail, and the county again saddled with a load of debt, as people were hungry and homeless, sullen, and in a fighting mood. Now the privation and distress were not brought about through pestilence or famine, or any cataclysm or vicissitude of fate or fortune. They were the direct result and logical sequence of the teachings of three men in the village. These men were Rev. Jonathan Mayflower; an editor with a past named Broadcast, who led a roving life until he settled in the village and embraced religion at a street gathering of the Salvation Army; and Mr. Redflame, an anarchist, who was converted at a prayer-meeting in Dr. Mayflower's church, and who since his conversion preferred to be known as a socialist. These three men, with the able assistance of Dr. Youngblood and his Free-to-All Dispensary, were responsible for the wretchedness and squalor now prevailing and rampant in the town, by teaching false doctrines and sowing the seeds of dissension and discontent.

Mr. Redflame, though ostensibly a socialist, had a *penchant* for lurid and turgescent oratory that worked the people up to a high pitch of excitement. His last effort in the now historic lyceum was noted for its very extravagant language. He belched out defiance and hate as the crater of Vesuvius pours forth its sea of flame. He so fired the hearts of his five hundred stalwart hearers that they shouted with one voice for free rent, free clothing, and free beer. This was considered a modest request by Mr. Redflame, and was not, after all, demanding too much, since they had already free coal and free bread through the kindness and industry of Mr. Mayflower, who buttonholed and personally canvassed every member of his church for a donation for the good work. Editor Broadcast had to do with the ice and milk funds, for which he advertised liberally in his paper, artfully slipping in advertisements as editorial matter and imposing on his readers, who believed that Mr. Broadcast was as

honest as he claimed to be, and that he had given up his bad practices since his conversion at the street meeting of the army.

Dr. Youngblood took care of the dispensary, and organized free excursions; also a gymnasium with a free-soup kitchen. Mr. Redflame declared, in one of his passionate appeals to the people, who were now too lazy to work, that wealth was a curse to the country; that rich men should be hanged, their property confiscated, and the proceeds divided among the poor. The earth, he said, belonged to all, and the fulness thereof; that as the earth was our common mother, it was our common heritage too. "Earth to earth, and dust to dust," was the behest and mandate of Heaven; that all were born free and equal, was the dictum and pride of this country of his adoption. In conclusion, he said, with forceful if not accurate diction: "The constitution further declares, 'Ours shall be a government of the people, by the people, and for the people.'"

The pastor, who was presiding officer at this meeting—Mr. Broadcast and Dr. Youngblood being vice-presidents—thought Mr. Redflame a little too radical in his views, and that he went out of the way to abuse the few rich men in his church. He told Mr. Redflame that if this extravagant language was repeated it would be instrumental in driving him from his parish and from a people whom he loved. He said the few wealthy men would go where there was more safety for their person and property; besides, that he had no ambition to be the pastor of a constituency of paupers in his declining years; furthermore, he had a family to support, and their welfare was a matter of much concern to him. So he cautioned the anarchist to be more careful in his future harangues at the lyceum.

The Pastor Suffers a Reduction of Salary.—Rev. Mr. Mayflower is much troubled; he paces the floor of his study with uncertain step. He has but just returned from his vacation trip to his annual haunts, the Berkshire Hills, when a committee of the trustees of his church knock at his study door. They have departed; the salary of the beloved pastor is reduced one-half. Another and more inflammatory speech had been delivered at the lyceum by Mr. Redflame, a week before the pastor's return. It was published in the *Wide-Awake Journal*, Mr. Broadcast's paper, which the sexton, Mr. Crowsfoot, saved for the pastor's perusal. The pastor, overcome with the fatigue of his journey and the excitement of meeting the trustees, is too greatly exhausted, and requests Mr. Crowsfoot to read the speech of Mr. Redflame to him. The sexton begins: "'Let the torch be lighted, lay waste their lands——'" "Stop! stop! enough!" cries the pastor. The sexton, who is absorbed in his subject and quite deaf, does not notice Mr. Mayflower, and continues to read: "'Let loose the dogs of war! let destruction and ruin, tornado and cyclone, wipe them from the face of the earth——'" "Stop! I say, stop!" cries Rev. Mr. Mayflower, with gesture as well as voice, and in anger; "Mr. Redflame has ruined my church, bankrupted myself, and leaves my little family almost homeless. I repeat, I want no more of him—I am through with him now."

Rev. Mr. Mayflower now Conscious that Some Atonement Should be Made for his Errors.—Rev. Mr. Mayflower was full of reminiscences, recollections that wrung his heart. He now recognized his mistake, and saw with open eyes the misery it had brought on others. Around him on every side was disaster, largely the work of his own hands. "As ye sow, so shall ye reap"—and had he not, with the help of Mr. Redflame and Mr. Broadcast, with the aid and counsel of Dr. Youngblood, sowed the wind of false doctrines of social economics among his flock, and was he not now reaping the whirlwind?

The pastor made some effort to reconcile his conscience to the altered situation, and in some measure justify himself, in that it was the result of good intentions; but he felt that was only an excuse—indeed, a subterfuge—since good intentions were branded in flame on lost souls. "The way of the transgressor is hard," and "The wages of sin is death," he saw emblazoned on the sky as he opened the window to get some air, for he was growing faint; but the sign in the heavens was the gleam from a burning church, and that church his own, and the letters painted there were only the reflex of a guilty conscience.

He then and there wished to imitate his prototype of the "Scarlet Letter"—the one eager to make atonement for a personal sin; the other for social heresies that, while not so intrinsically heinous, were deplorable, far-reaching, and disastrous in their results—by going to the lyceum, and under its shadow renouncing these social heresies and making recompense for his free-dispensary folly. But his moral courage failed; he could not summon a resolution strong enough to support his legs across the floor, much less undertake the more hazardous journey to the lyceum, where he had sat a listener to the fulminations of Mr. Redflame and indorsed them by his presence.

It was whispered by Dame Rumor that Mr. Redflame might know something about the burning of the church. This the pastor refused to believe, as he had given Mr. Redflame communion that day. He continued: "Mr. Redflame led our meeting only this evening, and made a touching prayer for the conversion of the heathen and a speedy gathering together of the nations in a brotherhood of love." The pastor resented the imputation on his parishioner, Mr. Redflame's, character. He said: "Human nature is not so base;" but the fire marshal and underwriters fastened the crime on Mr. Redflame, a jury convicted him, and the judge sentenced him to imprisonment for life.

It appeared at the trial that the motive which prompted Mr. Redflame to the crime was revenge directed against the pastor, as he was beginning to look coldly and frown on his lecture projects, and on the occasion of their last meeting the pastor had told him bluntly to leave off talking and go to work—that then, perhaps, others in the village would follow his example. To this Mr. Redflame made no answer, but the color came to his face and he bit his lips.

The Rev. Mr. Mayflower Angling for a New Charge.—Rev. Mr. Mayflower now rallied his shattered nerves, and made what reparation he could in helping to build up the community he was so instrumental in tearing down. He asked it as a special favor to him if Dr. Youngblood would be more careful and discriminating in the distribution of his charity, and cut off his free-soup kitchen attached to the lyceum, hoping by that means to send the able-bodied men loafing there to do an honest day's work. He also counselled him to hold out the olive branch to the other physicians in the town, as by this means he might be able to secure their co-operation and support in bringing about the prosperity which was now so much needed. At this moment the sexton, Mr. Crowsfoot, handed the pastor a letter. It contained a request from a deacon in a distant parish that he kindly occupy the pulpit in his church the following Sabbath, as the loved pastor ministering there had been called to his higher reward. Rev. Mr. Mayflower, on the following Sunday, preached from the pulpit left vacant by the sainted Dr. Stargaze. The Sunday-school superintendent, in describing the occasion to Dr. Hopewell, Dr. Youngblood's assistant, who had severed his connection with the Free-to-All Dispensary, and had started a private hospital on his own account in the town now the scene of his old pastor's new charge, said: "He took us by storm. His preaching had depth and solidity; its manner was

sharp, direct, incisive, with the thrill to electrify, the force to convince. The day he preached was a day of Pentecost indeed, and the people went on their way rejoicing." Let us add, the pastor rejoiced too, for he had a reasonable expectation of winning a rich congregation.

The Pastor's Farewell.—At home in his pulpit the following Sabbath the preacher is serious, solemn, and reminiscent. Grief is heavy at his heart and his eyes are suffused with tears, after the sermon—a model sermon, too—which was a review of his labors in the parish during a pastorate of ten years, a labor of love, but withal one of disaster to his hearers. Its humility and pathos made tears ramble down the wrinkled faces of the deacons, and brought sobs, subdued and plaintive, from the ladies of the congregation. He told eloquently how he wrestled in prayer, how the spirit of inspiration came upon him, how he was directed to accept the call from the distant parish. The people there were crying for spiritual food, and praying for a shepherd to lead them and keep them in the way; it was in obedience to a divine mandate and the will of the Master that he should labor in another field.

A solemn stillness fell on the people gathered there, buoyed up by the strong arm of Christian resignation and sustained by the faith that was in them; they were willing to let their pastor go. He departed, with the benediction of a congregation, which he had been so instrumental in bringing to famine and the poor-house, ringing in his ears, but whose members yet were kind, to fill the more lucrative pulpit in the distant parish.

Rev. Mr. Mayflower Not so Influential with Some of His Old Congregation.—Notwithstanding the injunction of the pastor, Dr. Black refused to have anything to do with Dr. Youngblood. He thought that to have any dealings with this man was like compounding a felony; indeed, it might be just as well to say it, he regarded him as a mountebank and charlatan, one by no means an ornament to his profession. Dr. Black's sterling worth commanded respect, and he now began to be influential in the reawakened community. He invited Dr. Goodman to deliver an address before the town council, and give his views as to the course to be pursued in order to bring back the prosperity that so long was a stranger to this now famished and desolate town.

Dr. Goodman's Address on Idleness and Industry.—"After watching the course of events for some time, and being a witness of so much want and sorrow in our community, I have been convinced of the fact that charity has its limit, and beyond that limit it loses its sweet savor and gives out a rank and unwholesome odor.

"When charity is dispensed at the expense of and to the detriment of others, it is an oppression working evil in two ways: the beneficiary of the charity will grow shiftless and lazy, while the donor will ultimately become dependent himself. His misapplied charity has poisoned the wellspring of society, torn that society in twain, sowed the seeds of privation, laziness, sedition, and crime. It has made fathers drunkards, homes cheerless, and mothers weep. It has, as you see by Dr. Youngblood's experiment, created an army of idlers that have voluntarily thrown down their labor to be partners in the era of good things promised by him and our late pastor, Rev. Mr. Mayflower. When people obtain the necessaries of life for the asking, what is the use or necessity for them to labor at all? Now our factories are closed, our fertile fields lie waste, our industries are paralyzed. The men to operate these varied industries are now in free-soup kitchens, on free excursions, or hanging around the corridors of free dispensaries waiting to be cured of imaginary ailments.

"Dr. Youngblood, Mr. Broadcast, Rev. Mr. Mayflower, and the notorious Redflame labored to inaugurate the workingman's millennium. Only one, however, of these men was sincere and honest in his purpose, and even he, when the storm broke and the bottom fell out of his project, like a rodent on a sinking ship, scented disaster and ran to cover by taking shelter in the pulpit of a prosperous parish. He had no scruples in leaving his old congregation in midocean with a stormy sea, to pilot their way unaided and alone to the spiritual shore. He left on the pretext that he was called through a dream—an inspiration—to take charge of a flock which was hungering for a spiritual love with which he was abundantly supplied and which he was able to distribute and bestow on all who applied at his open door.

"The stimulus to labor is, first, hunger; second, a desire for wealth. We cannot attain to the second except we appreciate and recognize the value of the first. This will explain why we have no millionaires at the equator, and so few in the tropics: there nature is kind and lavish to her children; there fruit supplies abound without cultivation; there the people have food without labor.

"This prodigality of nature takes away the stimulus to industry—namely, hunger; the incentive is not there. Nature here is the philanthropist; and has she not brought forth and reared her legions of degenerates? She left them without the stimuli to industry, but warmed their naked flanks in the rays of a torrid sun and lulled them to sleep in the shadow of eternal spring.

"The million that the philanthropist left last year to build a dispensary and found a home for destitute men, will prove a monument to his folly, a thing to mock his memory, a scourge to flog society. It will enlist an army of beggars, and, basking in the sunshine of this bequest and a beneficiary of it, will be found the anarchist with his torch, the socialist with his jargon, and the burly tramp with his bludgeon and his beer can. The philanthropist, while appeasing their hunger, takes away their stimuli to labor; for this they will repay society by goading it to anger and then stabbing it in the back. This will be their gratitude and the monument reared to the philanthropist's memory. As surely as the square of a straight line is equal to four times the square of its half, so surely will a charitable bequest be met by a multiple of poverty and a complement of crime.

"The abuse of charity has worked more mischief and brought more misery in its wake than have pestilence and famine. It has crowded our dispensaries to the doors, filled our poorhouses with wrecks of humanity, congested our prisons, and has always been a highway to revolution and the gibbet. Without that million the lazy man might work; with it, he will not, for while it lasts his incentive to labor will disappear. After he has drank his bowl of free soup and eaten the bread of idleness, he will talk of oppression, and whisper assassination to his fellow-mendicant, and smite the hand which fed him. That hand he declares has forged the chain and locked the shackles that made him a beggar, a bondman, and a slave.

"From time immemorial the problem has presented itself, how to help the poor, and what to do to relieve their needs and raise them to be self-supporting and units of value in the social fabric. With a blind and unreasoning zeal, Rev. Mr. Mayflower labored to solve this problem; but, as you all now see, his failure was as signal and complete as was that of others who went before him.

"As you have heard, the philanthropist left a million to found a dispensary and a home for destitute men. The climax of effort was reached when he rounded this so-called charity—really, however, only

a satire on charity—a dispensary, a home, and a free lunch for lazy men. He did not trouble himself to look below the surface or investigate as to what effect his charity would have on other enterprises and industries. His carelessness in this respect would lead one to the conclusion that there was a motive for his charity. Could it be possible that he, like Dr. Youngblood, wished only to advertise himself? If alive or if now dead, had he a morbid and mortuary ambition that his name should ring through the world, and redound to the interest of his estate and the glory and advancement of his heirs and legatees? The golden rule, 'To have a just regard for the rights of others,' he ignored, or if he considered it, brushed it aside with contempt, as did Dr. Youngblood the advice of the sage who pointed him the way to honorable success the morning he started on his eventful career. The observance of this rule is the guidepost to honorable and fair dealings among civilized communities. Why did the millionaire neglect to observe this rule? Let us in charity draw the veil over his motives, and say he was blind, morally blind, and that he felt he had discharged his obligation to society in founding the dispensary and home for destitute men; that he had rejoiced in the good he had accomplished and the monument he had raised to perpetuate his memory. But his work, as a matter of fact, has only begun; before him lie a wide field and boundless possibilities. He lost his opportunity by taking the advice of Rev. Mr. Mayflower and Dr. Youngblood. In this case it was the blind leading the blind, with the usual result—that both fell into the ditch. Now, what should this rich man have done with his wealth that he threw away in founding this dispensary and home, in order to confer a lasting benefit on his less fortunate fellow-beings? He should first have acquainted himself with the significance and import of the word charity—on which one word a volume could be written; second, he should have inquired into the cause of the poverty and distress that solicited his bequest, and, by removing the cause, wiped out the effect. Here is the rock on which his project foundered; he mistook the effect for the cause—the impact for the power behind—and was as successful in treatment as was the quack who told his patient he had dropsy, and set about blistering his swollen extremities in the hope of drawing off the fluid and mitigating his sufferings.

"The medical quack and the philanthropic quack stand on precisely the same level; both treated the effect for the cause. The quack added to the misery of his patient and hastened his death; the philanthropist's bequest was a stumbling-block in the path of progress, it robbed the people of the stimulus to labor, and was a direct hindrance to the advancement of the human race. It diffused laziness, dependence, and crime on every hand, as the sun diffuses light and heat.

"In the inauguration of this era of reform, what part has the rich man to play with his million? He must make an effort to develop the moral sense and awaken a pride for industrious activity in the recipient of his charity. If the man or the woman is lazy, the philanthropist must show him or her the necessity for energy and activity; if they are prodigal and improvident, he must impress them with the advantages to be derived from temperance and self-restraint; if they are illiterate and incompetent, he must teach them the meaning and usefulness of knowledge and the good that can be accomplished by being proficient in something in consonance with their intelligence, temperament, and environments—in short, he must instruct them in the value of self-reliance, dignity, and independence; that each individual should be self-sustaining; that intemperance and selfishness are barriers to progress, and not compatible with the higher development of our race. In proportion as this simple and easily digested philosophy is disseminated among the people, will poverty die out, and with it the poor-house, the jail, the free dispensary, and the five-cent lodging-house; for then the vexed social problem will have solved itself."

Dr. Youngblood, who was in the hall, left before the conclusion of Dr. Goodman's address. It was noticed that he was disgruntled and perturbed.

A Letter from the Pastor. — Dr. White, better known in church circles as Deacon White, read a letter from the old pastor, who still viewed his former congregation with a fatherly eye from afar.

"To my Old and Beloved Flock, with Greetings:

"Dear friends of the past, whose memory is entwined with sad recollections, our parting almost broke my heart; but, as it was my mission to go, I accepted the call with composure and resignation, believing as I do that it will not be long before the kind Providence that counts the hairs of our heads and keeps us in the hollow of His hand will fill the place so unworthily occupied by me with one who will carry on the work I left undone and bring back some who have wandered from the fold, to eat the husks and to drink the wine of a physical and temporary joy, that is shortlived and perishable. Keep firm in the faith, and hold fast to that which is good.

"Yours, in the hope and reward of a kindly life and a propitious future,

"Jonathan Mayflower."

The Deacon's Confession.—The letter from the old pastor fell like a bomb, charged with spiritual fire, on this little band of worshippers, now gathered in Dr. Youngblood's Memorial Operating-Room—though Dr. Youngblood was absent, having run away from the consequences of another shady transaction. They had worshipped here since the burning of the church by the anarchist Redflame.

Deacon Bloodgood, overcome by the whirlwind of joy that the reading of the pastor's letter called forth, being a good man, thought it no disgrace to make a few remarks about a thing that hung to his skirts and flapped its ugly wings, like a black cloud, over a conscience otherwise clear and a life without blame, and began:

"Fellow-Christians and loved ones, others before me have made confession to their shortcomings in this very operating-room, made memorable by the brilliant achievements of Dr. Youngblood's scalpel and the farewell address of Rev. Mr. Mayflower, and now hallowed by the pathetic epistle just read with so much eloquence by Brother White. An obligation was enjoined on all Christians when the word was spoken, 'Confess your sins one to another.' Now I must tell you with shame and humiliation the part I played in bringing about this reign of poverty and the general hard times that have pinched you so, robbing you of the pleasure of sending your annual donation this year to the board of foreign missions for the conversion of the heathen; that compelled you to cut down your beloved pastor's salary one-half; and that still compels you to worship in this Memorial Operating-Room. My resolution to make this confession became fixed when we had to build a new wing to the hospital of which your humble Christian brother is trustee; if possible, this resolution became more fixed after hearing the address of Dr. Goodman before the town council, of which I am also a member, and the report of the committee of that council that a new jail was necessary and imperative. It was conferring an honor on me, which I do not believe I deserved, when I was made president of the board of governors of the Free-to-All Memorial Dispensary, the walls of which shelter us now.

"As president of the board of governors of the Free-to-All, being a hardheaded business man before I became governor of our town hospital and president of the Memorial, I brought all the experience of forty years' close attention to business into my new offices. I saw around me an opportunity to build up the hospital and dispensary, and to accomplish this purpose utilized every force at my command. Good doctors were standing in line at the hospital gate, hat in hand, with credentials, waiting a nod or a beck from me, that would transform them into surgeons and visiting physicians at our hospital or dispensary. One of them told me that it was the American Derby of the profession, to secure one of these prizes I had at my ready disposal. He said that, having secured this prize, his futurity was already a reality; he would be talked about, called into consultation, and lifted above the heads of his brother practitioners, who after a little while—though jealous now—would learn to respect and esteem him themselves.

"My system of transacting business was so complete and perfect in detail, and the punishment for the infraction of a bylaw so condign and swift, that insubordination was rare and never formidable at our hospital or dispensary. Our effort to discriminate between the deserving and the impostor at our hospital gate was an imposition and a sham. While we pretended to treat only the deserving and needy at our hospital and dispensary, we waved to the crowds to come on. We wished to make a show; we had a mania for increasing the list of paupers and mendicants on our dispensary ledger, just as I had the burning ambition to outsell my neighbor in the leather business in the Swamp, years ago, before I retired to private life.

"Fellow-Christians, it has been said that the evil men do lives after them. The evil I have done lives now before my eyes; I can see it in your hollow cheeks and haggard faces, in your poorly furnished homes and naked children. The abuse of charity, as Dr. Goodman so well said, encourages men to idleness and paved the way to the poorhouse. I can see it all now. To increase my misery and fill the cup of my woe, I have still a sadder recollection to relate, and I relate it with fear and trembling, lest I should be struck dead by the righteous vengeance of Heaven for this traitorous, cowardly, and perfidious act of mine.

"In a moment of weakness, Satan whispered in my ear that the well-dressed and respectable element that crowded to my dispensary should have protection; that their interests, their honor, and their presence demanded some mark of recognition from the governors of the hospital and the Free-to-All Memorial Dispensary. They did not wish to be branded as paupers or considered as dependents; they were helping the institution by their names, and giving it tone by their presence; they were willing to pay a dollar a month to me, to take the sting out of charity and give them a true bill of lading for the full voyage and a cabin passage to health and activity, while the others, less fortunate, at our dispensary door, had to take refuge in the steerage. With shame and contrition, I here confess I acceded to this dishonorable, this outrageous demand, and gave these people—these paupers—rights and privileges properly belonging to the honest private patient who consults a physician at his office, and who was at one time—before the advent of my nefarious scheme and dollar-a-month abomination—willing and eager to pay for the same. This was the unkindest cut of all, a stab in the vitals, to the men who have made the practice of medicine honorable and have elevated its standard to a scientific calling. I closed the doors to a laudable ambition in these men, namely, to make a respectable livelihood and to be factors in the community for which they labored and amid which they cast their lot.

"Yes, fellow-Christians, these honorable and competent practitioners had to close their office doors because we inveigled and allured their patients to our dollar-a-month banquet; but our charity was a charnel-house, and our banquet the banquet of death to the community, and a spot that will not wash out on this conscience of mine. True, some governors of the hospital and dispensary opposed me in my action; but, as the contest was close, my vote was affirmative and decisive.

"The practitioner fought manfully for his rights at first, but it was the battle of the many with one; it was his little office against our organized opposition. He succumbed in the unequal struggle. It is written: 'The race is not given to the swift, nor the battle to the strong.' This is demonstrated by the poverty now prevailing, and further demonstrated by the sign in the heavens seen by our late pastor, Mr. Mayflower, in the reflection of his conscience and the burning of his church. I told my brother governors at our meeting yesterday that this abomination should cease—that charity was beautiful, but masquerading in her garb was a crime that would not go unpunished. I pointed out the deplorable condition of the industries, the army of idlers in the street, and the destitution we had brought home to the legitimate practice of medicine.

"These injustices were kindled into life by our abuse of sweet charity, and fanned into flame by the dollar-a-month monstrosity and abomination. This hybrid monster, with the face of charity but the body of a misshapen and hideous demon, is sapping the lifeblood out of the community to-day. It is a stench in the nostrils of honest manhood, and, I repeat, an abomination, a crime. True, it has put a few dollars in our coffers, but it is the price of our treason and the blood of an honorable and deserving profession.

"Brother governors, we tried to accomplish an impossible feat in our effort to unite charity with manly independence. They spurned each other. Charity is lowly and vaunteth not herself. She seeks poverty in the slums and byways, and teaches it the language of independence and the lesson of stalwart manhood.

> "'She takes the filth-stained ivy
> From pauper and from slave,
> To teach the languid wires
> The sounds that manhood gave.'

"She lifts it from its lowly habitation and starts it on its journey with the force and impetus that commend it to success."

The governor continued: "While charity may associate with poverty and squalor, they will not assimilate; they have nothing in common; their relative characters and features are as different as day is from night, light from darkness, beauty from a shapeless mass of ragged rocks.

"The complement of their social equation is the monster we have conjured into life—namely, the dollar-a-month dispensary fraud, that I feel, as you all can read, branded on my forehead now. By this fraud we have inoculated charity with a virus and defiled her by its touch—the beautiful goddess we have thrown into a sewer, to be transformed by the slush into a monument to our perfidity and treason. I repeat, fellow-Christians, I cannot justify myself before you or hide behind a legal opinion of Justice Youngman. I want to bear the full burden of my shame, and as such make some atonement for my crime."

The deacon, overcome by exhaustion from the expenditure of physical energy and mental excitement that his confession had occasioned him, for he was an old man, sank into his chair, crushed, defeated, and covered with humiliation.

A hungry physician, also a member of the little congregation, was an interested listener to the deacon's confession, and with more zeal than discretion, and without the consciousness of doing an injury or injustice to any one, recited the lines:

"The desolator desolate,
The victor overthrown,
The arbiter of others' fate
Now suppliant for his own."

The good deacon, with his face buried in his hands and happily unconscious of what was transpiring around him—his thoughts turned inward on themselves—was automatically chanting:

"Rock of ages, cleft for me,
Let me hide myself in Thee."

Dr. White's Temptation.—It can be seen that from the abuse of hospital charity, and the hard times and financial stress prevailing, the honest physician was a sufferer. One of these sufferers was Dr. White, who though old had yet some vigor in him, enough to resist temptation and fight the battle for the profession in which he took such pride and of which he was glad to be accounted a member. No patients were coming to Dr. White's office, and he had few outside calls. The popular tide was running high, and it set toward the Free-to-All Memorial Dispensary; it threatened to swamp and carry the old physician in its path.

One day, at the springtide of its flow, the old physician was jostled, elbowed, and trampled on in this mad rush of the human tide to the Free-to-All Memorial Dispensary and soup-kitchen annex. This old man's little store was fast disappearing, like snow under the rays of a hot sun. Starvation stared him in the face. Just like his old pastor, Rev. Mr. Mayflower, he cared not for himself; it was for his family—they were all to him.

At midnight Dr. White was aroused from a broken slumber by another physician, whom he was rather surprised to see and at such an unusual hour, for he had only the most casual acquaintance with him, and gave this acquaintanceship the most formal acknowledgment to the physician living so near his door. This visitor was a successful quack, whose heart was touched by the woes and poverty he saw reflected in Mrs. White's face as he passed her on the street the other day. He came at midnight, as if he hoped the darkness would hide and shelter him in the commission of a dishonorable act. He came to tempt Dr. White. Dr. Dash was affluent, and the partner in business or crime of Dr. Bounce, the hustler in their symptom-blank, flimflam, and tricky advertising schemes. He had houses and lands, blooded stock, and a magnificent town residence; his business offices on the thoroughfare—for privacy would be fatal to him—were fitted up in gorgeous style. He also had a pew, but not in Rev. Mr. Mayflower's old church. He gave liberally to foreign missions, paid tribute to the political bosses to nominate a political king to reign over him and protect his interests. He was the right-hand man of the pastor, and chairman of the board of trustees of his church.

He told Dr. White that he understood his poverty and the source from which it came, that he saw a way of deliverance for him, that he would lead him into that way, and once there he could take care of himself in the journey to prosperity.

Slipping into the doctor's hand a check for $50, he requested him to get out of bed, as he wished a further interview in the parlor.

"'Come into my parlor, said the spider to the fly.'"

Dr. White's eyes blinked and snapped when on the threshold of the door. It was from the flash of the diamond displayed in the immaculate bosom, and the electric apparatus attached to the kodak of Dr. Dash. With kodak ready, he said he wanted two pictures of Dr. White, one before and one after treatment. He wanted them for the *Wide-Awake Journal* next morning. He said it was a kind of reversal of custom, as in the first snap he wished him to look just as he was, woebegone and careworn. In the second shot he was to look pleasant, as if his sufferings were over and he saw new light.

Dr. White was about to expostulate, when shut off by his visitor: "Only your consent, Dr. White, merely your consent; I do the rest. It is to say over your own signature how you were cured of a long-standing deafness and a defective sight, after all other means failed to give relief; to tell of the days of agony and nights of misery you were compelled to endure, when noises, like the roaring of many waters and sounds like the belching of a locomotive, swept like a blast-furnace through your tortured brain. It is to tell how the celebrated Professor Long was puzzled, baffled, to understand the cause or apply a remedy to your disease; to say that the famous Professor Short was equally helpless; and how both failed to mitigate your tortures or give any relief; to tell in song and story how the combined talents of your great medical lights failed and paled, like the light of a tallow candle in the blaze of the midday sun, when pitted against the skill and inimitable art of the celebrated specialists, Drs. Dash and Bounce, with offices on the Boulevard. Doctor, do not hesitate or throw away a golden opportunity. I assure you, Dr. White, the practice of medicine is a business like any other, the object of which is to make money; if it fails in this respect, it fails altogether." He told the doctor that medical etiquette did not pay rent, and that hunger could not be appeased by membership in a medical society or even by being a fellow of an academy.

He continued: "Fine feathers make fine birds, but the most beautiful and graceful of these birds—namely, the peacock, which is also known as a proud bird; in fact, symbolical of pride and vanity—if shorn of his plumage and plucked of his feathers, would make a rather poor Thanksgiving dinner. The turkey is my symbol; you can have the peacock as yours. To be sure, the turkey is not handsome, but is withal heavy and substantial, and has a fragrant odor for a hungry palate."

Continuing, he declared: "The peacock is all show and no reality, the turkey is clumsy but juicy; the one appeals to the eye, the other to the stomach. I repeat, you keep your fine bird; I am satisfied with mine. Dr. White, let me tell you, all the medical etiquette in the universe is not so potent to drive a creditor from your door as a ten-dollar bill.

"The quacks are not skilled in the amenities and folklore of your nonsensical societies; your bylaws are feeble to punish the guilty, and helpless to protect the innocent. You are held together by a rope of sand, an illusion, an *ignis fatuus*. The philosophy of your boasted societies is largely metaphorical and founded on a misconception of human nature, which any of you thirty or more years in active practice have found out to your cost.

"This is why I left the fold and took to the road as a medical pirate and brigand, where your sympathies and all your energies should have been enlisted. You were only disinterested spectators, and left me to fight the battle alone, to be crushed and defeated, while my cause was a just and holy one. Like a high-spirited and honest woman driven to the street, I was driven from the fold. Your societies talk loudly and learnedly about the public health, and your efforts to advance and elevate the public morals. When it fails to protect those of its own household, how can it hope

to be successful in a wider field? This is why, dear doctor, you cannot impress your individuality on the public mind or manners, and why you are now and always will be, till the coming of the millennium, negative and feeble in affairs of finance and state. I have further discovered that the members of your societies are interested in their individual interests, rather than in the welfare of the societies as a whole. I repeat, Dr. White, any body of men calling themselves a society in the arts and trades, so regardless of the welfare and interests of its members, could not hold together half a year. But enough on what has no interest for me. What occupies my attention now, since I left your society, is making money and watching the district attorney, by being careful not to step over the danger line into the domain of criminality; however, it is only fair to say that that functionary has given me very little trouble. He acts with regard to me as if he were under some mesmeric spell or other occult influence, or a resident or guardian of the interests of some other planet than ours.

"The reason may be this: looked at in a commercial sense and latter-day light, mine is a legitimate business, just like the grocery, the drygoods, or the furniture trade. The grocer, the drygoods man, and the furniture man cry fraud on each other. The grocer says his brother in trade adulterates his food supplies, and that his brother is a fraud and a cheat; the same cry is raised by the drygoods man and the furniture man against each other—that he is procuring money under false pretences. They lie in advertising their wares; I lie in advertising mine. It used to be that all was fair in love and war, but now business has a place on this black list of social piracy that has thrust itself through the public conscience, and choked that conscience into silence with its glamour and its gallantry. The district attorney thinks so too, since he has not to my knowledge prosecuted any of these fraudulent concerns, though like myself they are breaking the law every day in dishonest practices. I have not even heard the voice of the press, the boasted guardian of the public weal and honor, though waiting to hear that voice long. I suppose it is stifled, hushed, drowned, by the flood of advertisements these fraudulent business concerns turn into the feed trough of that press. That is the reason it is mum about my own fraudulent advertisements on diseases I have not cured and about a public I have fooled. My advertising roll of bills has a sedative influence on its bellicose and caustic pens. The press does not care a rap for you, Dr. White, or your societies, since you send no advertising grist to their mills."

Dr. White, his face already pale, grew paler. He summoned the remnant of the little force that slumbered within him, and, rising from his chair, he began:

"Dr. Dash, if your visit to me to-night was one of a single purpose—that purpose to do good without hope of reward—my pride, my manhood would rebel and cry out against being the recipient of charity from any one, much less from you, sir, coming here for the purpose of advancing your own interests, masked by the plea of benefiting a fellow-man in distress. Your proposition I scorn; it is monstrous; it outrages every manly and honorable impulse that my nature is capable of conceiving. I refuse, sir, to accede to your request, and hand back what you considered would be the price of my shame. I have been honored in peace and in war. Here are the emblems of this appreciation and honor; here the medals and tokens I have loved so long and well, which you see adorn this threadbare coat of mine, and which will go down to the grave unsullied and untarnished by any barter for lucre. They stand for worth and sturdy manhood, for an honest cause and a noble profession. Go, Dr. Dash; I refuse to be tempted. My family will be protected when I am gone. Shipwreck and starvation may come; but disgrace, never. Welcome—

"'Death, the old man's friend,
The kindest and the best.'"

The Summary of Causes Leading to the Abuse of Charity.—In the foregoing sketch a few of the leading causes for the abuse of medical charity are given; there are other causes, but, since brevity and time are precious, they will not be touched on here. However, no suffering or hardship will be entailed on account of this omission, since they are mostly auxiliary and offshoots of the original and principal grievance cited in this article by example and illustration—which method to the writer's mind is the best possible way to present a truth. By this means a fact is made more palatable, and an impression is produced far more enduring than by the old method of generalization and moralizing—reaching conclusions by comparison, deduction, and inference. The one entertains while it instructs; the other, by its monotony and infinity of detail, obscures and buries in a grave of verbose redundancy the main facts sought to be impressed.

Dr. Youngblood is the incarnation of the pernicious activity and commonplace audacity with which the medical profession is to-day honeycombed, undermined, and disgraced. The Youngbloods have made our calling the jest of the people; they have so injected the element of fakir and three-card-monte man into the current of medical thought that the honest and intelligent practitioner blushes while contemplating the future of his profession. These Youngbloods have divided, demoralized, and prostituted our profession to their own selfish ends, so that it is an easy prey for the wily hospital governor to feed on or the philosopher to base a truth or point a moral with.

Mr. Broadcast is the soul and embodiment of the unscrupulous, dishonorable editor, who will stoop to anything to further and advance his individual interests. While one sheet of his journal is devoted to editorials eulogizing fair business dealings, the other side is full of fraudulent advertisements; with one hand he smites the usurer and locks the embezzler in a cell, while with the other he receives the reward of conspiracy and cunning from his partnership with the dishonest business man, the impostor, and the quack.

The Rev. Mr. Mayflower is a type of the clergymen who are preaching from their pulpits and proclaiming from the lecture platform their sympathy with the poor, and the efforts they are making to advance the interests and better the condition of the laboring classes. These clergymen are loud in their condemnation of any scheme to improve the condition of the general practitioner, who they say has no grievance, and whose business it is night or day to answer the call of all who may apply at his doorbell, without being inquisitive as to whether he will receive a compensation for his services. These reverend gentlemen claim that the physician has no moral right to ask for a reward for his labor. "This should be left to the generosity or judgment of the patient," say these obliging gentlemen. By preaching such doctrines and emphasizing these absurd assertions in private and public, they have inflicted a hardship on the medical profession, and largely contribute to make the poor poorer and the discontented more discontent. They, more than any other cause, have helped to fill the waiting-rooms of the hospitals and dispensaries with medical paupers; and, worse yet, they put seditious words in their mouths and revolutionary ideas in their heads about the rights of the poor and the duty of the government.

The anarchist, strange to say, is largely the product of the social teachings of the Mayflower brand of clergyman, who is careful to run away from trouble him-

self and better his condition whenever an opportunity offers. He is perfectly willing to leave his old flock to shift for itself, to hope and pray as best it can.

Dr. Dash is a sample of that moral reptile known as the advertising quack. The effrontery of this man is remarkable. By organized fraud and misrepresentation he reaps his harvest of dollars and flourishes like a green bay tree, notwithstanding that the searchlight of an aroused public opinion is directed on his methods. He still reposes with a beautiful serenity in the confidence of his victims, and, like the surgeon of the Free-to-All Dispensary, hides behind the fog of legal technicalities placed on the track of justice by Mr. Sharp, his attorney.

The pernicious influence of the Youngbloods, Mayflowers, Broadcasts, Redflames, and Dashes must be destroyed before any diminution in charity abuse is possible. The combined influence of these men is the moral Saint Lawrence feeding the gulf of charity. Behind this gulf is a perverted public sentiment, fed by millionaires and some well-meaning philanthropists—as the teeming waters of the St. Lawrence are fed by the great chain of North American lakes.

The hospital governor is only a condition, a mere incident in this Niagara of charity, a sort of caretaker at the falls, so to speak. The poor, helpless man is as unable to shoot these rapids as was Dr. Goodman or the Rev. Mr. Mayflower; indeed, he must use extreme caution that he is not drawn into the vortex and swallowed in the maelstrom of the seething waters of the abyss below. He is ultimately in as much danger for his life as was old Dr. White in being swept away by the human tide that rushed through the thoroughfare to the Free-to-All Dispensary.

The hospital and its adopted child, the dispensary, will collapse, shrinking to their normal proportions, when rich men are convinced that it is not to their interest to contribute further to the maintenance of these institutions. Rich men as a rule are selfish. It is the lack of generosity and kindness in their natures, as much if not more than business ability, that contributes so largely to their success. In order to acquire their wealth, what human wrecks are strewn in their wake! what a cyclone of misery has been the companion of their triumphal march!

> "Ah! that some warning vision there,
> Some voice that might have spoken."

The millionaire treads on broken hearts, lacerated feelings, and blighted pledges—all offered as a sacrifice on the altar of mammon. While treading on the graves of his victims and in possession of the millions his soul craved for, he suddenly experiences a revolution of feeling and has a religious spasm, the reflex of a troubled conscience, which impels him to build a chapel, found a hospital, or endow a dispensary. He is as selfish in his new enterprise as he was in the accumulation of his millions, and persistently refuses to take those into his confidence who could show him how to make his bequest of the greatest good to the greatest number of human beings, and very probably, like Dr. Youngblood, wishes to advertise himself while playing the rôle of philanthropist and humanitarian.

Conclusions.—The problem of the hour, then, is to convince rich men that their interests are assailed and their future is imperilled by the countenance and aid they are giving to indiscriminate charity; that this so-called charity is a two-edged sword, and will cut both ways. This cannot be done by the gathering of a few well-meaning gentlemen at a hall on Madison Avenue, or by the protest of a State medical society at its annual meeting. However honest in purpose, they succeed only in making themselves look ridiculous and a plaything of the great public, which is looking through the fence across the way. The efforts of these gentlemen very much resemble that of the famous old lady in her heroic endeavor to hurl back and stem the rising tide with her broom, or the fisherman to drain the ocean with an oystershell. The public will say that we are interested parties in the matter, and not likely to give a disinterested opinion; that our meetings of protest are made up largely of two classes, the big fellows and the little fellows—namely, those who are able and those who are not able to make a living at practice; that the big fellows are helping the little fellows to climb the apple tree; that it is a contest where there is only a plaintiff in the suit and no action at law.

Some good has been accomplished, however, and in the right direction, by a few writers in the medical press, notably by that well-known and long-time champion of the general practitioner, Dr. George F. Shrady, of New York. The Titanic blows of this sturdy yeoman through the editorial columns of the MEDICAL RECORD, resound through the medical world; the echoes of these blows have awakened the millionaire and philanthropist to hear that their interests and their future largely depend on the manner and method with which they handle this new danger, how to control and regulate the problem of charity.

Is it any wonder, then, as the poor physicians survey the field and recognize the overwhelming odds against them—the forces with which they are to compete, the crowd outside and the many in their own ranks—that they grow despondent, and exclaim in their anguish of soul, "What must we do to be saved?"

51 CHARLTON STREET.

STOMACH DISTURBANCES CAUSED BY HERNIA OF THE LINEA ALBA IN THE EPIGASTRIUM.[1]

BY CHARLES D. AARON, M.D.,

[illegible]

INSTRUCTOR IN [illegible] IN THE DETROIT COLLEGE OF MEDICINE.

I WISH to report an interesting case that has come under my notice. It is a case of subperitoneal fatty hernia of the linea alba. The practitioner does not expect a hernia in the neighborhood of the epigastrium, for it is well known that that is quite rare. Still it is of the utmost importance to those of us who are giving especial attention to diseases of the digestive tract to bear in mind that hernia in the epigastrium does occur more often than supposed. These herniæ are obscure because usually they are small and elude detection. The case I refer to will illustrate how a small subperitoneal fatty hernia will give all the symptoms of gastric disturbance.

April 13, 1892, Mr. D——, a cigarmaker, aged forty-nine, consulted me for what he called gastric catarrh. He gave the following history: He enjoyed good health until four years before he consulted me. While eating his dinner he was suddenly taken with nausea and vomiting. Ever since he has suffered in various ways, and has given such symptoms as to lead his physician to believe he was suffering from a stomach disorder. Sometimes he feels comparatively well, and at other times his trouble is aggravated. He complains of pain in the epigastrium. When I saw him first he had a thickly coated tongue, complained of headache and loss of appetite. He had lost twenty-eight pounds in four months, and was unable to retain food in his stomach. He vomited milk and soup just as he did meat and potatoes, and suffered with constipation. The urine was normal.

Upon physical examination I found the stomach in normal position and was unable to discover any or-

[1] Read before the annual meeting of the Northern Tri-State Medical Association at Detroit, Mich., July 15 and 16, 1897.

ganic disturbance except midway between the xiphoid appendix and the umbilicus. Here in the median line, by palpation, I felt a lobulated mass, which was flattened and not larger than a small chestnut. It was slightly movable, and felt soft and boggy. My patient knew nothing of the existence of this small enlargement. I paid little attention to this protuberance, but my patient began to get weaker, and all treatment which apparently seemed rational was without results. He would vomit upon the slightest provocation, and suffer severe pain, extending to the back, after any food had entered his stomach. I concluded that the trouble was a reflex nervous disturbance, and the mass in the linea alba was the cause of it. Upon examination I could not get the typical signs of hernia—fulness on coughing, etc. Unable to find much literature on the subject, I called in Dr. T. A. McGraw, and we agreed upon a diagnosis of hernia in the linea alba.

April 21, 1892, the patient entered Harper Hospital.

April 22d, I assisted Dr. McGraw in the operation. A one-inch vertical incision was made over the protuberance, passing through skin and subcutaneous tissue. We immediately came upon the tumor, which consisted of a lobulated mass of fat. It was covered by a layer of thin connective tissue, which continued from the base of the tumor as a pedicle. On lifting the tumor a minute opening was observed in the linea alba, through which the pedicle passed. Care being taken that no part of the neck was caught in the ring, the pedicle was ligated as deep as possible. The stump retracted within the opening in the linea alba. The pedicle extended through the linea alba and a part of the peritoneum adhered to the tumor, as is usual in these cases. The ring was hardly larger than the diameter of a match. The edges were denuded and the aperture was sutured. Union took place by first intention. The mass was not larger than a flattened chestnut and was lobulated. Our diagnosis was a subperitoneal fatty hernia of the linea alba. The patient made a rapid recovery. His diet was at first fluids and gradually solids. All symptoms entirely disappeared, and he was able to resume work six weeks after the operation. This he had been unable to do for two years previously.

The patient left the hospital, March 5, 1892, fourteen days from the time of the operation. It is now five years since then, and he has had no return of his trouble.

During my stay in Berlin I had the pleasure of seeing three such cases at the Augusta Hospital Polyclinic. Dr. Leopold Kuttner, assistant to Prof. C. A. Ewald, was kind enough to demonstrate the cases to me. Since then he has reported several cases in an elaborate paper.[1] These cases had been sent to the Augusta Hospital Polyclinic by physicians as stubborn cases of gastric catarrh. They had evidently failed to make an adequate diagnosis.

There was at one time a disposition to consider every kind of dyspeptic difficulties, excluding catarrh, ulcer, and cancer, as a neurosis of the stomach. We are gradually coming to know that gastric neuroses cover a number of various symptoms, each of which upon a careful examination may have a respectively different cause. Still we must confess that at times it is difficult to differentiate between a functional and organic disease, with regard to stomach affections.

Lindner,[2] in an exhaustive work on abdominal hernia, points out the fact that patients often complain of gastric disturbances, undefined pains, etc., while upon more careful examination small herniæ are found to be present. At times these herniæ are hardly larger than a pea. If careful palpation is omitted, such patients are usually treated for gastric catarrh, intestinal catarrh, etc., and, to the surprise of the physician and patient, all means apparently rational are without results, until a cautious and practical examination recognizes the cause to be a hernia of the linea alba. Lothrop[3] says that, owing to the great density of the linea alba, the rupture in hernia epigastrica generally starts to one side of the median line. When once there is a small rent in the fascia, the abdominal pressure forces a small portion of the pliable subperitoneal fat through the slit, both of which slowly enlarge. Later a portion of the peritoneum is dragged after the fat, and thus we have the beginning of the hernial sac, the outer surface of which may be covered with a layer of fat. He says that when once this peritoneal pouch has been formed, the entrance of omentum or gut is easily understood.

Statistics show that hernia epigastrica is more prevalent in men than in women. At one time it was supposed that all cases of hernia in this region contained a part of the stomach. This we know now not to be true. They may contain subperitoneal fat, peritoneum, omentum, large intestine, small intestine, all together or any one of these singly. At times it is impossible to ascertain whether the omentum is in the sac or not, but when the hernia is of any considerable size the omentum is usually present. Litten has given us a method by which we can differentiate the subperitoneal lipoma from hernia containing omentum, etc. He places his hand over the hernia, telling the patient to cough at the same time. If the sac contains omentum and intestine, we get the impression as if water were being squirted against the hand or shot thrown against it; if not, he decides that there is a subperitoneal fatty hernia.

Hernia of the linea alba occurs usually in the upper part of the abdomen. It is found mainly between the tip of the xiphoid appendix and the umbilicus. Rarely do we see these herniæ below the navel. Above I said that the male sex seems to suffer more frequently with these herniæ than the female. I believe that the cause of this lies in the fact that hernia epigastrica has often been mistaken for hernia ventralis; this led to the notion that it occurs in women more often than in men. The size and form of these herniæ are variable, and range from those of a bean to those of an egg. The form depends on the size—the small ones are usually round, while larger ones hang down like a bag.

The symptoms of fat and intestinal hernia may for a long time be latent, and such abnormalities may often be found without symptoms. Symptoms may manifest themselves suddenly. Pain may show itself in paroxysms, after the taking of food, coughing, etc., and may encircle the body and run down the legs. Patients complain of pain on bending, and vomiting is a common occurrence. Pains seem to be greater after taking solid foods than after a fluid diet. There are several varieties of typical symptoms; loss of appetite, nausea, flatulence, constipation may occur in light cases. Along with these symptoms which point to disease of the digestive organs, the disease may assume the form which resembles hysteria, neurasthenia, and melancholia.

Most convincing in the diagnosis of hernia epigastrica is the evidence of a tumor by palpation, which is less difficult the larger the protuberance. Important is the sensitiveness to pressure. This point is diagnostically valuable if the hernia is small. The chemical and microscopical analysis of the stomach contents usually shows that gastric functions are normal.

[2] Lindner, Berliner Klinik, [illegible]

[3] Lothrop: The Boston Medical and Surgical Journal, March 4, 1897, p. 201.

The symptoms of true intestinal hernia of the epigastrium resemble those of subperitoneal lipoma so much that a complete distinction between them is at times difficult to make. However that may be, from the viewpoint of the practitioner this differentiation is of no material importance, since operative measures are equally necessary in both cases.

THE DIAGNOSIS OF CHOREA IN ADULTS.

By W. MOSER, M.D.,

THAT chorea is not infrequently seen in childhood is universally conceded. In adults, however, it has been hitherto regarded as comparatively rare. Recently Krafft-Ebing informs us that chorea in adults is not so infrequent as is generally believed, and that it has in them a different significance than in children. In extreme old age it is certainly not a common disease. I have seen three cases of chorea in adults since the publication of Krafft-Ebing's article, and this I do not regard as a mere coincidence, but rather as confirmatory evidence that the disease is not so rare in adults. It may be questioned whether in adults we are dealing with the same disease as occurs in children. Choreiform movements in adults may be a symptom of organic cerebral disease, as in prehemiplegic or posthemiplegic chorea (Weir Mitchell, Charcot). Choreiform movements may occur during pregnancy. They are rare, however, and the high mortality leads me to believe that we are confounding organic cerebral lesions with true chorea or choreiform movements as we see them in children.

Chorea proper usually gives a favorable termination, although I have seen two fatal cases in children. No autopsy was made. Chorea may be associated with hysteria, as in the electrical or rhythmical chorea of French writers, and there are also the choreiform movements occurring in alcoholic subjects (alcoholic chorea). These cases are not properly chorea, nor are they influenced, as is the large majority of cases of true chorea, by the administration of arsenic. The form of the disease known as Huntington's chorea, while it has features in common with chorea proper, still has some important differences. It is seldom seen before middle life. It occurs more frequently in males than in females, develops gradually, and late in the disease the mind becomes affected. It does not improve under arsenical treatment. Choreiform movements may be local, *i.e.*, confined to one member, as an arm, and if they do not soon yield to the administration of arsenic it is to be feared that they may be the precursor of cerebral hemorrhage. When choreiform movements follow a cerebral hemorrhage, they are known as postparalytic chorea. The symptom known as athetosis (Hammond) is a form of local chorea, and signifies organic brain lesion, usually cerebral hemorrhage or sclerosis, and, as Wood truly says, it is "only one of an innumerable variety of posthemiplegic spasms, and is never exactly the same in two cases." The condition known as hemiataxia "may be considered simply as a very mild form of postparalytic chorea" (Wood). In reviewing the different forms of chorea just mentioned, it becomes apparent that we cannot always be dealing with a disease *per se*, or a disease identical with the functional chorea or chorea minor of children. But it is the chorea minor of adults which forms the subject of this article, and like the disease in childhood it frequently presents the following peculiarities:

1. Great emotional disturbance, such as fright, acts as a cause, and did so in one of the three cases mentioned, that of a young lady of nineteen years.

2. Its association with rheumatism or a rheumatic history. In one of my cases a lady, aged thirty-two years, gives a rheumatic history.

3. Its association with endocardial lesions.

4. Last, but not least, it is usually improved by the administration of arsenic, while choreiform movements of organic cerebral origin are not. Nor is hysterical chorea improved under arsenic. The same might be said of paramyoclonus multiplex, with which the disease in question might be confounded.

I regard arsenic in chorea minor as a specific, like quinine in malaria or mercury in syphilis. Hence in a given case of chorea, especially if it be localized, as in an arm, and no improvement takes place, there arises a suspicion in my mind that it depends upon serious cerebral lesion and may possibly be the precursor of cerebral hemorrhage.

FORWARD DISLOCATION OF THE FOREARM.

By HENRY D. FULTON, M.D.,

THE forward dislocation of both bones of the forearm at the elbow is of such infrequent occurrence that the following report of such a case may be of interest. The case presented two points of special interest: first, it was unattended by fracture of the olecranon, and secondly, the displacement occurred when the forearm was in a position of complete extension. The case was seen in consultation with Dr. F. G. Gardiner of this city.

The subject was a man of middle age, muscular in build, and at the time of the accident intoxicated to a moderate degree. The history which he gave, and which was corroborated by a friend with him at the time, was that while he was about to step from a freight car, and while still holding securely to the iron support at the end of the car, used by trainmen in getting on or alighting from a car, the step turned, throwing his foot off, the entire weight of his body being for an instant sustained by one arm, when the luxation occurred at the elbow. As above stated, there was no fracture of the olecranon, which has complicated six of the twenty cases of this dislocation which have so far been reported ("American Text-book of Surgery," page 439). The end of the humerus formed a large prominence posteriorly, causing a marked and sufficiently characteristic deformity. The radius and ulna were completely displaced upward upon the anterior surface of the humerus. Efforts to effect reduction without anæsthesia were unsuccessful. After the patient was thoroughly anæsthetized the parts were restored by our combined efforts to their natural relation. The reduction was somewhat difficult and was obtained by making extension by pulling on the hand and wrist while the forearm was maintained in a flexed position at right angles with the elbow.

Hamilton states, in his work on "Fractures and Dislocations," that Sir Astley Cooper and others denied that this dislocation could occur without fracture of the olecranon, but that the possibility of its occurrence is now well established. The last edition of Gross' "Surgery" mentions that there have been ten instances recorded of this dislocation without fracture of the olecranon, and later works cite fourteen cases so far authenticated. In previous cases of this rare dislocation which have been reported, the mode of production has invariably been stated to have been some force or a blow on the olecranon process of the ulna when the forearm was in a flexed position. The history of this case is perfectly clear on the point that the displacement occurred when the forearm was in extension.

Progress of Medical Science.

The Treatment of Trifacial Neuralgia by Ligation of the Common Carotid Artery.—From a survey of the literature, together with experimental observations upon dogs, Ricketts (*Journal of the American Medical Association*, October 16, 1897, p. 772) concludes that ligation of the common carotid artery, in the absence of pathologic conditions, is attended by but little danger. It is safer, more certain, and attended with fewer serious consequences than any of the intracranial operations for the relief of trifacial neuralgia. The cause of this condition seems to be either congestion or anæmia; when congestion, ligation is the more certain to bring relief. The close proximity of the ganglion to the bone upon which it rests and the weight of the brain upon it, together with localized meningitis, seem to explain in some degree the occurrence of anæmia and congestion of the ganglion. The cellular structure of the ganglion is not changed by ligation of the carotid artery, so that no such alteration can be assigned as the cause of relief from pain. As the size of the blood-vessels on the side ligated does not seem to be diminished at the end of eight weeks, the cause of relief lies evidently in the fact that the blood pressure is much lessened, inasmuch as lowering of arterial tension in any congested area affords relief. However uncertain the cause of the pain or of its relief, ligation of the common carotid artery must be recognized as an established operation in the treatment of trifacial neuralgia.

Ichthyol in Variola.—Dr. Kolbassenko (*Le Scalpel*, October 3, 1897) reports that he has employed ichthyol in eighteen cases of variola, only two of which were fatal; these two cases were in a very serious condition when he undertook the treatment. From the time of appearance of the variola papules to the disappearance of the pustules, the following pomade is to be applied three times daily over the entire surface of the body: ichthyol, 10; oil of sweet almonds, 60; lanolin, 20. For economy in hospital practice vaseline may be substituted for oil of sweet almonds. During the stage of the prodromic fever until the appearance of the papule, *i.e.*, from the time variola is suspected, the author applies all over the body a liniment containing equal parts of essence of eucalyptus, of ether, and of lanolin. This treatment has the advantage of suppressing, so to speak, the itching in the state of eruption; of diminishing fever in the state of suppuration (the temperature will not rise above 39.5° C.); of diminishing the suppuration itself, and of shortening by one-half the desquamative stage.

The Virulence of the Bacilli of Loeffler in Connection with the Clinical Forms of Diphtheritic Angina.—Dr. G. H. Lemoine writes, in *Le Bull. Méd.*, No. 51, June, 1897, that in thirty-seven cases of pseudomembranous angina with the bacilli of Loeffler, the bacilli extracted from the false membrane were found pathogenic. Twenty-nine of these anginas had the clinical features of diphtheria; on the other hand, the remaining four were benign and the bacilli were devoid of virulence. In the cases in which the bacilli were virulent, long and moderate forms were found, except in four cases, in which the short form existed and the bacilli were of attenuated virulence. One can say that generally there is an agreement between the results of bacteriological and those of clinical examination as to the nature of diphtheritic angina. It is the same if one wishes to base the gravity of the affection in man on the bacteriological examination, since animals are chosen that are excessively sensitive to the bacilli of Loeffler. In three serious cases of true diphtheria the Loeffler bacilli showed themselves attenuated, but bacteriological study shows considerable virulence of the coli bacilli and the streptococcus. The greater or less resistance of the organism ought to be taken into account. In practice one cannot rely exclusively on bacteriology to yield the diagnosis of diphtheritic angina. The exclusive presence of the bacilli in the short form ought to lead us to reserve our decision. The long and medium bacilli appear to be characteristic of diphtheria. But in every case it is necessary to take into account the number of elements found; not only the number of colonies developed on the Semon's tube, but also the quantity of bacilli entering into the constitution of the false membrane. An examination of the false membrane, detached with forceps and washed in sterilized water, has given conclusive results in cases reported by the author; and in a patient who died of strepto-diphtheria, he was also able to affirm the association of the streptococcus. The clinic remains at the foundation of the diagnosis of diphtheritic angina; it alone indicates the time of intervention; bacteriology will indicate the manner of intervention.

Acetonuria, Diacetonuria, and Butyric Acid in the Gastro-Intestinal Troubles of Infants and Young Children.—Dr. P. Vergely (*Archives Cliniques de Bordeaux*, September, 1897) draws the following conclusions from his study of this subject: 1. The presence of acetone, diacetic acid, and oxybutyric acid in the urine of infants affected with digestive troubles is quite frequent. 2. These digestive troubles have particular physiognomy due to the formation of these substances in the digestive tract. 3. The presence of oxybutyric acid, of diacetic acid, and of acetone in young subjects, when the kidneys, the liver, the lungs, and the nervous system are free from serious lesions, gives a favorable prognosis. 4. It is possible that oxybutyric acid, diacetic acid, and acetone are formed in the digestive tract by the action of micro-organisms or of albuminoids and sugars of the alimentary mass; that with these harmless materials introduced into the blood with albuminoids and with fat by the fact of autophagy may be the point of departure for the formation of acetonuric products. 5. The meat diet ought to be proscribed and carbohydrates ought to furnish the nourishment during the acute period. One should have recourse to different evacuants, purgatives, and emetics, and these should be followed with alkalines, glycerin, hypophosphites, and soda—at least in non-diabetic subjects.

Spleno-Pneumonia in Typhoid Fever.—Drs. Auche and Carrière, in the *Archives Cliniques de Bordeaux*, September, 1897, draw the following conclusions from their article on the above subject: 1. Spleno-pneumonia ought to be classed among the number of complications possible in typhoid fever; but it is very rare, two cases only having been reported up to the present time. 2. This complication comes at an advanced period of dothinenteritis. Its first symptoms have been noticed on the seventeenth or eighteenth day after the beginning of the fever in Dr. Bouicli's case; during the convalescence from a slight relapse in the writers' personal observation. Its progress may be rapid and its termination speedily fatal, or it may follow a slow evolution and present the ordinary prognostication of the disease of Grancher. 4. Its anatomical substratum consists in a pulmonary congestion, as shown in the macroscopical and microscopical examination of Bouicli's case. 5. As to the pathology, in the authors' case it was as obscure as it is in such instances generally. "It seems from the result of our studies that the bacilli of Eberth ought not to be incriminated and regarded as the direct cause of this complication. It is

necessary to look for the pathological element in the white staphylococci, which we have cultivated. Their feeble degree of virulence, their existence in a state of purity in our best cultures, make us believe this. Staphylococci are so widely scattered, one being able to find them particularly in the surface of the skin even after the strictest antiseptic precautions, that we cannot feel justified in implicating them."

Experiments with Koch's New Tuberculin.—In a review of the recent work with this remedy, Maere has reported (*Le Scalpel*, October 3, 1897) seven cases of lupus treated by injections of the new tuberculin. Doutrelepont (*Deutsche med. Woch.*) has used it in fifteen cases of lupus, the greater part of which presented tuberculous ganglia. He considers the new tuberculin superior to the old, and is of the opinion, as far as he can judge at present, that it constitutes a valuable therapeutical agent. He has been struck, as has also M. Bussenius, with the fact that its action varies with the length of time that it has been bottled. It seems imprudent to him to follow the directions of Koch for increasing the dosage. The amount must be increased more slowly if fever is to be avoided; such fever may be only temporary, but it affects the general state of the patient. These fevers have caused the patient to lose in weight, while generally there is an increase in weight during treatment. Locally the ulcers of lupus are rapidly cicatricized, the projecting parts do not give way, the nodules are replaced by cicatricial tissue. The ganglia have diminished in volume, but some suppurate and have to be incised. Baudach reports having made two hundred and eighty-five injections in twenty patients. He has not observed a single abscess, though De la Camp and Rumpf, of Hamburg, say they have often observed at the point of injection painful infiltrations, yielding to treatment slowly. Five of Baudach's patients have followed the treatment to the end; this has required from sixty-four to seventy days. One patient withdrew from treatment; thirteen others are still under treatment. The injections seem to give good results. They sufficed in one case to close a rectal fistula. This treatment should not interfere with hygienic measures and an outdoor life. Spengler, the former assistant of Koch, is a firm believer in the new product, and declares that it causes less reaction than the old; the cough diminishes under its influence, as well as expectoration. Ulcerations of the larynx heal more rapidly than when touched with lactic acid. In one case of mixed infection with fever it was harmful and had to be discontinued. Splengler is very careful in applying this treatment to patients, using it only with tuberculous patients whose temperature does not exceed 37.5° C., or a temperature under the tongue of 37.2° C. It is necessary that expectoration should show the absence of all secondary infection; such infection may be possible even in the absence of fever. He makes the injections in the posterior side of the forearm. When the doses are raised from five to twenty milligrams the injections are no longer made every two days, but at intervals of from five to eight days, in order to avoid the accumulation of the tuberculous toxins in the system. From the outset it secures against attacks of fever. He advises very sensitive patients to replace the injections by rubbings with the remedy. On the other side, Jez (*Wiener med. Woch.*), after treating six patients, contests all immunizing and curative power of the tuberculin. He notes violent attacks of fever, aggravation of all symptoms, an increase of the râles and of the number of bacilli in the sputum. R. Muller opposes the use of tuberculin in case there are tuberculous complications of the ear. One woman, who had lupus and tuberculous otitis of the left ear, had during injections an attack of miliary tuberculosis in the right ear. Two English clinicians report, in the *British Medical Journal*, that they have treated six cases of lupus by the new method, and confirm the assertions of Koch as to the local action of the remedy. They note a diminution of congestion in the parts surrounding the lupus; the development of a depression in the centre of the nodule, with consecutive desquamation; the healing of the ulcerated surface; the gradual disappearance of the œdema of the lips, ears, etc. In two cases the lupus nodules have disappeared; in two other cases the nodules shrivelled up. In a particularly tenacious case the process was partially checked from the beginning of treatment. It is only at the time that large doses have been injected that marked febrile disturbances have been observed, with turgescence and inflammation of the local lesion, but these attacks have quickly yielded. Without committing themselves on the question of a possible cure, these authorities believe that they can recommend the method, at least in cases of common lupus when the general condition is still good. It is interesting, *à propos* of the widely differing results that tuberculin treatment has given, to mention the information collected by Dr. Rembold, of Stuttgart. He treated, from 1890 to 1891, with the old tuberculin, 82 cases. After six years he has attempted to ascertain what has become of these patients, but has been able to trace only 70. Of these 70, 27 only had a mixed infection, the importance of which was then ignored. They are all dead (23 died the first year, 2 the second, and 2 the third). These figures show that patients belonging to this category cannot hope for much from tuberculin. The remaining 43 are divided into three groups. Serious cases, 12; 10 died, 2 better and living. Moderately severe cases, 15; 7 died, 8 living and better. Mild cases, 16; 1 died, 3 living and better, 12 cured. Out of the 43 cases, 18 dead, 12 better, and 13 cured.

Treatment of Wounds by the Aseptic Cage.—To avoid the drawbacks of the present methods of dressing in extensive burns or granulating surface wounds generally, Dr. J. R. Benson has for some time employed a method of treatment which consists in applying no dressing of any kind to the wound, but leaving it exposed to the air under a kind of cage covered with dry dressing. This cage may be applied with ease to any part of the body. Dr. Benson proceeds in this manner: A piece of tin of sufficient thickness is cut so as to form a splint for the part to rest on, with a number of long processes projecting at the sides. These processes are bent over the wound, leaving a space between them and the latter, forming a cage. The cage is attached by strapping above and below the wound, and the whole is covered with a dry aseptic towel. In large body wounds ordinary wire cradles will answer the purpose; if the wound is small, two pieces of glass tubing may be strapped to the skin and gauze stretched over them. The gauze and towel are removed from time to time, and the wound is washed with a weak aseptic lotion. In cases of skin grafting Dr. Benson covers the grafts with protective and pressure is applied in the ordinary way. About six hours later the wound is undressed and the cage applied. Care should be taken not to remove the protective too soon and not to let it remain too long. In the former case serum is poured out between the wound and the grafts, preventing them from adhering; while in the latter case the transplanted grafts become adherent to the protective and may be dragged off with it. The wound is douched once or twice a day with a 1 to 2,000 mercuric-chloride solution. Skin grafting in this manner becomes a fairly easy operation, the results being certain and invariably successful.—*Medical Week.*

MEDICAL RECORD:

THE CONDITIONS OF MODERN NAVAL WARFARE.

IN the late war between China and Japan, naval warfare on a large scale and under modern conditions was for the first time fairly exemplified. Without doubt, if the Japanese had met foemen more worthy of their steel, the lesson taught from a medical and surgical point of view would have been even more instructive. However, quite enough facts have been gathered to demonstrate plainly that a complete revolution has been effected in the methods of naval warfare. Not only has it been shown, as might have been anticipated from the nature of the new conditions, that the wounds received were of a more fearful and generally of a different character, but it also has been clearly shown that the shock to the nervous system from the noise and vibration was terrible—in some instances, indeed, fatal. Dr. S. Suzuki, fleet surgeon in the imperial Japanese navy, read before the International Congress at Moscow a paper treating of the wounded in naval battles between Japan and China, together with some notes on the sanitary conditions of the navy during the war. This paper has just been published in pamphlet form. Many interesting details are given. The principal seat of injuries appears to have been the head, while the hurts causing the largest number of deaths were those affecting larger parts of the body. This was a natural result, because in the majority of these cases at least one-third of the body was burned and in some wholly destroyed. It is pointed out that in sea fights most of the wounds are in the head, and in land fights in both extremities. The explanation is that in land fights soldiers as a rule are injured only by shells and bullets, whereas in sea battles all materials around the combatants, as ship planks and rigging, etc., being blown to pieces by the bursting of shells, increase the causes of injury. The antiseptic treatment, which was of course pursued, seems to have been attended with most satisfactory results. No infectious diseases of wounds occurred, with the exception of one fatal case of erysipelas. There was one case of burns leaving remarkable keloid scars. The sanitary condition of the Japanese navy was throughout the war excellent. Venereal disease and its sequels supplied 37.69 per cent. of the total number of cases of disease. Diseases of the respiratory system numbered 9.01 per cent.; diseases of the digestive system, 10.09 per cent.; and skin diseases, 8.91 per cent. There were 167 cases of malarial fever, 4.79 per cent. of which were fatal. But 3 cases of cholera occurred in the Japanese navy. Of the 43 cases of kak'ke, 3 were fatal, the ratio of cases per 100 of force being 0.21. Of the total number of persons dying at sea during the war, 150 were killed in action and 177 died of disease.

TYPHOID FEVER IN RELATION TO WATER.

IT is somewhat of a coincidence that Dr. Hart's summary report of typhoid-fever outbreaks in Great Britain should have been published at the time when one of the most widespread and virulent epidemics of that disease which has ever occurred in England was raging at Maidstone. It is now some sixteen years ago since any report on water-borne typhoid was made in Great Britain. The subject matter of that report was also collected and published by Dr. Hart. In the present summary the question of typhoid fever in relation to water is treated in all its aspects, and many details are given of epidemics in all parts of the United Kingdom. Referring to the change that has come over the minds of the people in regard to the dangers lurking in water, the author says: "The time is not long since, however, in which much scepticism existed in this country as to the bad effect on health of even considerable amounts of organic impurity; but in the interval the theory previously held by the majority of medical sanitarians has received the added weight of exact experimental research and proof. It no longer remains a mere theory, but is now an accepted fact, the remaining difficulty being to make people see that the existence of disease-provoking properties in their neighborhood in relation to their drinking-water is such as needs removal, when such removal entails expenditure of money." These words apply with as much force to the people of America as to those of England.

Dr. Hart is in accord with the majority of experts in trusting to filtration as the most efficient method of purifying water, but he is not in accord with the modes of filtering in general use in Great Britain. On this subject he says: "In the matter of filtration I am much afraid we come very far short of that point of perfection to which it were well that we should attain. The theory now advanced concerning the filtering of drinking-water, which eats at the very heart of our preconceived notions as to the treatment to which our filter beds should be subjected, has also brought with it the statement of the only position which it is safe to adopt, if we are to be free from the danger of recurring outbreaks of typhoid fever by reason of our water supply becoming polluted in a manner not to be rendered harmless by our prevailing methods of filtration. To such of my readers as have not studied the paper of Prof. R. Koch on 'Water Filtration and Cholera,' I would say, do so; and I would further lay stress on the rules which are therein laid down for the frequent and regular bacteriological examination of water from each separate filtering-basin and before the water has

been allowed to pass into the general storage reservoir, as also to the rule as to the construction of the filter beds in such manner that improperly filtered water can be at once removed, not being allowed to mix with the other water to be delivered to the distributing mains."

The pamphlet throughout is well worth a study by those interested in public hygiene.

COMPARATIVE POSITION OF THE ORDINARY GENERAL PRACTITIONER HERE AND IN ENGLAND.

Competition, associated with other causes, has for some time past pressed very heavily upon medical men in this country. Their average income is smaller and their future chances are not nearly so bright as they were but a few years ago. The reduction in the earnings of doctors is not confined to the United States, but is a worldwide evil. These remarks apply to the rank and file of the medical profession only, and not to the specialists who in every land may be said to form a separate class. In Great Britain, indeed, the position of the general practitioner has become so precarious that an absolute dread as to the ultimate result is pervading its ranks, and remedies are being suggested and sought for on all sides. Thus from a contemplation of the state of affairs in the old world, the doctors here may extract some grains of comfort. It is always consoling to the ordinary individual to know that there are others in a worse plight than himself. In the first place, the expense of a medical education in Great Britain averages more than in America. To obtain a degree or qualification in any medical school in England, Scotland, or Ireland, a course of study covering a period of at least five years is compulsory and entails an expenditure of a no less sum than $3,000. *The Lancet* and *British Medical Journal* put the cost at a much higher figure. When, after these years of work and anxiety and after spending this amount of money, the student succeeds in obtaining his license to practise, what are his prospects? If he possesses money, all well and good. At any rate he can make a fair start, but if he has no means, what then? At the outset he may be fortunate enough to earn an income of from $250 to $400 a year as an indoor assistant to a practitioner; as a ship's surgeon he may be paid as much as $40 a month; a parish appointment may afford him perhaps $250 yearly; or, lastly, if he will consent to pocket his pride and lose much of his self-respect, he may open in the poor suburbs of London or in the slums of one or other of the large towns, what the inhabitants of these districts briefly term the doctor's shop, and there retail medicine and advice for twelve cents and pay a visit for twenty-four cents. Again, take the case of a young man in Great Britain, who either through interest or the possession of capital is able to commence life as a general practitioner under more favorable auspices, and compare his chances with those of the beginner here. It is stated in the *British Medical Journal* on well-informed authority that the average income of a doctor in Great Britain does not exceed $1,000, so it may be taken for granted that the average yearly earnings of those starting practice is very considerably less than this sum. On equally authentic authority it is asserted that the average income of a medical man here after about five years' practice varies from $800 to $1,500, and that the income of a practitioner of twenty years' standing can be estimated at not less than $2,000. But this is not all the advantage the doctors on this side possess. It is when we review the fees in detail that the great difference in the pecuniary position of medical men here and in that of their brother practitioners in England is most clearly appreciated. Incomes in this country may be estimated at nearly double that on the other side, while fees average nearly four times as much. Reference has already been made to some of the fees in the poorer districts of the large towns in England. It may be added that in the gricultural parts of the country they are not much higher, besides being more difficult to collect. Here no self-respecting doctor will take a fee of under half a dollar for an office visit, or less than a dollar for an outside visit. For midwifery he will expect at least $15 (the average in Great Britain is about $5). In England a doctor has to do more than twice the amount of work in order to earn the same income. Finally there can be no doubt that the ordinary working member of the medical profession in this country is in a comparatively better position, in addition to having a brighter outlook than one of the same class in England. Into the question of causes in both countries there is no need to enter.

WHAT THE "MEDICAL RECORD" DOES.

The *Buffalo Medical Journal*, in an editorial in its issue of October last, referring to the late Moscow congress, says: "The Medical Record has published a full cabled synopsis of the proceedings, which is a marked instance of journalistic enterprise as well as lavish expenditure."

So far as we know this is the only reference which has been made in any American medical journal to what has been the most difficult and expensive attempt on our part to supply our readers with the news of the day, *pari passu* with its occurrence.

Remarkable as is the occasion, it is perhaps not to be wondered at, since any such reference would only go to show the lack of the same enterprise and expenditure on the part of any metropolitan journal so noticing it. We refer to it here simply to impress upon our readers the fact that the Medical Record never spares expense in providing material and news which the wide-awake members of the medical profession should have to keep themselves in the front rank of scientific progress. Its corps of regular correspondents all over the world is, unquestionably we presume, the largest and most complete of any. We think it will hardly be considered egotism for us to say that it is the one journal which is indispensable to all who

desire to be informed promptly of the progress of medical science and of medical news. While we make this claim for the MEDICAL RECORD, we must reiterate what we have repeatedly said in these columns before—that no medical man who can afford it should neglect also to subscribe for and do what he can to support and encourage his local medical journal. With that and the MEDICAL RECORD coming regularly to his table, he could be no better equipped if he subscribed to a dozen other journals, so far as periodical literature pertaining to his profession is concerned.

A SIGN OF PROGRESS IN AMERICAN PSYCHIATRY.

THE recent appointment of William Krohn, Ph.D., a psychologist, to a position on the staff of the Eastern Illinois Hospital for the Insane, is of sufficient importance to deserve more than passing notice. Time was, and that not far removed, when the appointment of a professional psychologist, not a physician, to a salaried position in an insane asylum would have been looked upon as an unwarrantable procedure, an unjustifiable expenditure of public funds, and an encroachment upon the rights of the physician. Happily neither physicians nor the laity take such a biassed view to-day. It may confidently be predicted that the advent of the psychologist to the asylum will be followed in time by a better understanding of morbid mental processes. Moreover, the benefit that should result from the co-operation and intelligent collusion of the physician and psychologist will be reaped not alone by the participants, but by the patient, for it has already been shown that occasionally the outbreak of an attack of insanity is heralded by phenomena that can be interpreted and given their proper significance only through psychological tests. The possibility of studying the association of mental conditions with different pathological states, and the genesis of the former as indicative and dependent upon the latter, may eventually suggest to physicians some means for the alleviation of the conditions thus heralded before they have progressed to a stage that makes recovery impossible. Naturally such study can be made by the physician if he has received training in the theory and practical applications of psychology, but unfortunately such training is uncommon. In some countries of Europe, particularly in Germany, a few psychiatrists have had adequate preliminary training in psychology, and this training has been reflected in the character and worth of their real contributions to psychiatry. Such work has been done, for example, by Krapelin, the director of the Psychiatry Clinic in Heidelberg, a pupil of Wundt; by Trüper, of Jena, also a pupil of the same master; while in our own country the promising work that has been begun by Hoch, of the McLean Asylum, and Meyer, of the Worcester Asylum, both young men trained in psychology as well as in medicine, is worthy of mention. We do not, of course, contend that it is necessary to be a professed psychologist before undertaking the work of a psychiater, for we are deeply cognizant of the fact that the latter may evolute into the best type of the former. In support of the statement we may cite the brilliant work that has been done in psychology by Ziehen, of Jena, who represents the psychiatrist in psychology: but as a rule it will be found that better results may be expected if the training in psychology follows the training in medicine, than *vice versa*.

One cannot be cognizant of current opinion among medical men, particularly among those who are working on the problem of disordered mental processes, without being strongly impressed with the emphasis that is being placed on the importance of bearing general psychological facts and principles upon the diagnosis and treatment of diseased states of the mind. Despite this recognition on the part of physicians, the extension of psychology into the domains of medicine has been brought about by the psychologist, the one important exception being that of Ziehen, referred to above, and perhaps also of Morselli. If it be granted that the study of psychology and its application may be of service to mental medicine, we may naturally look for its inclusion in the curricula of the more advanced medical schools. Indeed, it has already been made an optional subject for fourth-year medical students in the University of Pennsylvania. We may likewise expect to see an affiliation of the professed psychologist with institutions for defectives and the insane, and the appointment of Dr. Krohn we consider a step in the right direction, as was the appointment of Dr. Lightner Witmer, professor of psychology in the University of Pennsylvania, a few years ago, to the position of consulting psychologist to the Pennsylvania Institute for Feeble-Minded Children, at Elwyn. Such appointments indicate a distinct advance in the working correlation of psychology and mental pathology, and as such they deserve the attention and emulation of managing boards of other institutions and of State commissioners of lunacy.

THE VENOM OF SNAKES AND ITS ANTITOXIN.

FROM very early times medical science has been searching to discover a counteracting agent to the venom of snakes. In India it is estimated that on the average more than twenty thousand persons die annually from the bite of the hooded serpent. Up to last year all these efforts to find an antidote had been in vain, when almost simultaneously Calmette at the Pasteur Institute and Fraser in Edinburgh claimed to have discovered an efficacious antitoxin. Many nations and races low down in the scale of civilization have been for ages in possession of the knowledge whereby they could render themselves immune to snake poison. The negroes of the Guinea coast, some Kaffirs in South Africa, and the fakirs of India are among those who know of this safeguard. The method practised by these people is either to eat the snake or to inoculate themselves with the venom itself. Different animals are affected in different degrees by snake poison. Calmette and Fraser first ascertained by a

series of experiments on various animals the minimum fatal dose. This was found to be exactly in proportion to the body weight of the animal. After this point had been settled, the attempt was made to secure immunity for these animals against poison. This was effected by gradually increasing the dose, until finally the original fatal dose had been largely exceeded. Calmette by this method rendered animals proof against sixty times their normal minimum dose, while Fraser made a rabbit able to withstand fifty times the ordinarily fatal dose. As yet direct experiments on man have been too few clearly to demonstrate his susceptibility to snake venom, but it has been conjectured that his omnivorous character would place his susceptibility between that of a cat and that of a rabbit. Hence to kill a man of ordinary weight, from 2.16 to 2.31 grains of venom would be necessary. In India and elsewhere Calmette's method has been tested with successful results in a few cases of snake poisoning. One authenticated case of a human subject occurred at Saigon, where an assistant in the laboratory was bitten in the hand. The hand and forearm were quickly paralyzed, and the serum was not injected until one hour after the bite; nevertheless the man after passing a bad evening recovered during the night. The methods of Calmette and Fraser differ. Calmette advocates injection while Fraser believes in swallowing the venom. Weir Mitchell supplied Fraser with the venom of three species of rattlesnakes (Crotalus horridus, adamanteus, and durissus) and also with a specimen of the copperhead. Experiments have thus been made with the venom of the most deadly poisonous serpents of Asia, America, and Australia. However, before a definite opinion can be given as to the orrhotherapy of snake bites, further experiments and evidence will be required.

PRINCE BISMARCK'S DOCTOR AND MEDICAL PRACTICE.

Dr. Schweninger, the medical attendant of Prince Bismarck, has lately been giving his views on "medical men and medical practice," and from his position these views naturally arouse much more interest among the laity than they deserve by reason of either originality or soundness.

He is not by any means a believer in up-to-date medicine. In regard to the present-day doctor, he observed that he is surgeon, bacteriologist, electrician, anatomist, microscopist, physicist or physiologist, but is very little of the physician. He looks upon modern pharmacy with great contempt, and he extends this contempt to the medical men who, from misguided enthusiasm or mere self-interest, assist the pharmaceutical specialist in making a fortune at the expense of gullible humanity. As to the new discoveries of medical science he contends that they are either useless "Aborigine" or old remedies long since tried and abandoned. The corset in the woman and the silk hat in the man he believes to be the two great sources of ill health. Vaccination he believes in to a certain extent, but regards compulsory vaccination as a piece of useless barbarity. Cycling he condemns and opines that the physical advantages attending this modern mode of locomotion are apt to be too dearly bought.

News of the Week.

An Italian Sewer in the Fifth Avenue Water Pipes.—The *Medical Times* of this city calls the attention of the health board to the fact that the large water pipes which are being laid in Fifth Avenue have been used by the workmen as a urinal, if not worse, during the protracted time during which this work has been going on, thus defiling the water supply to the level of a common sewer. The writer says that from the window of his sanctum he has seen this done, and can thus substantiate the truth of the statement from personal knowledge.

The Harlem Medical Association.—The regular meetings of this society will be held hereafter at Arthur Hall, Lenox Avenue between One Hundred and Twenty-sixth and One Hundred and Twenty-seventh streets, on the second Monday of each month, except July, August, and September.

The Chicago Pathological Society.—The annual address before the Chicago Pathological Society will be delivered on the evening of Friday, December 3d, by George M. Sternberg, M.D., surgeon-general of the United States army. The subject of the address will be "Yellow Fever; Its Etiology and Pathology."

Laying the Cornerstone of the New Bellevue College.—On Saturday afternoon last, the cornerstone of the new building of the Bellevue Hospital Medical College was laid with appropriate ceremonies. Mr. D. O. Mills, president of the board of trustees, presided. The Rev. Dr. Roderick Terry delivered a prayer and then Dr. Austin Flint introduced Dr. Lewis A. Sayre, who laid the cornerstone, and in his address described the founding of the college and reviewed briefly its later history. The remaining exercises were held in the lecture room of the Carnegie Laboratory. Addresses were delivered by Dr. Landon Carter Gray, representing the alumni, the Rev. Dr. Roderick Terry, D.D., of the board of trustees, and Dr. John S. Billings, representing the medical profession. The cornerstone contains among other things a small vial of diphtheria antitoxin and a tube containing spores of the bacillus aerogenes capsulatus, which we trust may not lead to a gangrene of this venerable teaching-institution. The new building, which will occupy the southwest corner of Twenty-sixth Street and First Avenue, adjoining the Carnegie Laboratory, will be six stories high and seventy-five by one hundred feet in dimensions. It will be constructed of brick and gray stone, and will be fireproof. According to present expectations, the building will be completed by the time the next college year begins.

Dr. Laporte's Condemnation.—Subscriptions are being solicited among physicians by several of the journals in France, not only to secure a fund for Dr.

Laporte, recently condemned for malpractice, but also to raise the amount necessary for having the case re-opened in the courts. The Société de Médecine, which is the oldest medical body in France, has passed resolutions of sympathy for the unfortunate physician, and of condemnation of the injustice done him by the court, recommending that a new trial be sought.

The Late Dr. William Thurman.—The West End Medical Society, at its regular meeting held on the 7th inst., upon recommendation of a committee consisting of Drs. Edward J. Ware and Charles A. Kinch, adopted the following minute: "The West End Medical Society records with sorrow the death of an associate member, Dr. William Thurman, and offers the following testimonial of our regard and appreciation of his noble qualities. He was a conscientious and successful physician, and well informed in all the departments of medicine. He preferred family practice and was especially interested in the little children. He was generous to the younger members of the profession. He was interested in many charities and freely gave his time, money, and professional talents to their advancement."

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending November 13, 1897. November 8th.—Surgeon James R. Waggener relieved from the *Marion* and ordered to resume duties at Mare Island navy yard. Surgeon C. Biddle detached from duty at the navy department, 12th inst., and ordered to the *Newport*, 13th inst. Passed Assistant Surgeon C. H. T. Lowndes detached from the Washington navy yard, 12th inst., and ordered to the *Newport*, 13th inst. Surgeon J. E. Gardner, detached from the *Dolphin* and ordered home on waiting orders.

College of Physicians of Philadelphia.—A stated meeting of the section on general medicine of the College of Physicians of Philadelphia was held on November 8th, the president of the college, Dr. J. M. DaCosta, in the chair. Dr. F. A. Packard discussed methods of prescribing diet in private practice, and exhibited an elaborate diet sheet permitting the indication of foods that are to be avoided as well as those that may be taken either in moderation or freely. Dr. Hermann B. Allyn reported a case of locomotor ataxia with perforating ulcer of the toe, and exhibited the patient. Dr. J. A. Scott exhibited the brain, the kidneys, and the heart from a case in which death had resulted from a copious extravasation of blood into the basal ganglia of the right hemisphere, rupturing into the lateral ventricle, and extending into that of the opposite side. The heart, although free from gross valvular and endocardial or myocardial change, was immensely enlarged; and the kidneys, small and white, were in a state of parenchymatous inflammation.

Philadelphia County Medical Society.—A stated meeting of the Philadelphia County Medical Society was held on November 10th, the president, Dr. James Tyson, in the chair. Dr. George E. de Schweinitz reported a case of abscess of the orbit resulting from suppurating ethmoiditis, in which recovery from both primary and secondary conditions followed evacuation of the pus accumulation and drainage. Dr. Louis J. Lautenbach read a paper entitled "Philadelphia's Gas-Supply in its Relation to Public Health—A Comparison of the Injurious Qualities of Coal Gas and Water Gas." He pointed out that water gas is much the more poisonous by reason of the larger quantity of carbon monoxide it contains, while on the other hand coal gas is the more explosive from the larger proportion of marsh gas contained. Dr. Philip Fischelis read a paper entitled "The Use of Electrolysis and the Galvano-Cautery in the Treatment of Diseases of the Nose and Throat." Dr. Joseph Gibb read a paper on "The Differential Diagnosis of Ulcerative Diseases of the Larynx and Pharynx." Dr. G. Betton Massey made a demonstration of an original process by which nascent mercuric salts are cataphorically conveyed into the body, and presented a patient in whom a large swelling of the upper jaw had been dissipated by means of the procedure, which consists in the passage of a current of from three hundred to one thousand milliamperes or more through a gold electrode with an amalgam coating of mercury.

Is Medicine a Trade or Business?—An English contemporary says that in the lease of many London houses there is a provision forbidding the carrying on of any trade or business, and it has been decided by the courts that the business of treating the sick is one of the forbidden trades.

Pathological Society of Philadelphia.—A stated meeting of the Pathological Society of Philadelphia was held on November 11th, Dr. A. C. Abbott in the chair. Dr. Joseph Sailer exhibited a heart, the seat of old pericarditis, presenting an aneurism close to the apex of the left ventricle, which had ruptured, and a second aneurism projecting from the posterior aspect of the ventricle. Histologic examination disclosed the existence of myocarditis, which, together with the aneurismal formation, was attributed to the antecedent pericarditis. Dr. Sailer exhibited also lungs from a case of purulent pneumonia, with metastatic abscesses in the kidneys. Dr. Judson Daland exhibited an appendix vermiformis containing a pin and successfully removed by operation. Dr. J. D. Steele presented a review of the literature of Koch's tuberculin. He also exhibited a specimen of hemorrhage into the lateral ventricle, with enlargement of the heart and chronic parenchymatous nephritis. Dr. J. H. McKee exhibited a rabbit presenting an umbilical hernia containing what was supposed to be a diseased vermiform appendix, but upon more careful examination proving to be a remnant of the round ligament of the liver. Dr. D. Riesman exhibited a specimen of carcinoma of the stomach with ulceration and metastasis to the liver; and also gangrenous lungs.

Philadelphia Pediatric Society.—A stated meeting of the Philadelphia Pediatric Society was held on November 9th, the president, Dr. J. P. Crozer Griffith, in the chair. Dr. J. H. Jopson demonstrated a case

of congenital hereditary œdema in a child, five years old, that had been under observation from birth, and whose brother presented a like condition. According to the history, the father had suffered similarly in childhood. The patient presented exhibited a firm swelling of both legs and, in less degree, also of the thighs, with a large pad of œdematous tissue on the dorsum of each foot. The mental state was good and there were no other abnormal manifestations. It was generally agreed that the condition was a developmental or embryologic one, and it was suggested that thyroid extract might prove useful in treatment. Dr. F. A. Packard read a paper upon the treatment of intussusception from the medical standpoint, relating the history of a case in which operation was required and terminated fatally. He pointed out the rarity of the disorder, and expressed a caution with regard to the avoidance of too great pressure in attempts at reduction by hydrostatic means. Any other means than surgical intervention, to be successful, must be instituted early, as swelling, adhesion, and ulceration are likely to have taken place in the course of two or three days. Dr. Edward Martin discussed the subject from the surgical point of view, agreeing essentially with the propositions made by Dr. Packard. Dr. R. G. Le Conte read a paper on "Intussusceptions of the Post-mortem Type Observed during Cœliotomy," reporting a case in which this condition was found.

The Silent Profession.—A writer in the *Chemist and Druggist* falls foul of *The Times* for venturing to assert that the profession as a body is not esteemed as it should be probably, adds *The Times* writer, because the medical profession as a body has taken no pains to establish and defend its position. This is not the opinion of the editor of the *Chemist and Druggist*, who roundly declares that "if there is one class of men who more than another is everlastingly clamoring for more recognition, more rights, and more privileges, it is those doctors." If adds this genial critic, their wisdom is no more conspicuous than their silence, it does not amount to much. With respect to the charge of silence, we are told that "the silent-suffering, self-sacrificing profession is almost as successful a feat of imagination' as the large profit alleged to be made by druggists on the sale of nostrums.—*The Medical Press.*

The Clinical Society of Elizabeth (N. J.) will hold a series of special meetings during the coming winter, at which there will be lectures on various topics delivered by invitation by out-of-town physicians. The first lecture of the series was delivered on October 28th, by Dr. R. T. Morris, of this city, the subject being "Appendicitis."

Village Water Supply in England.—A writer in the *Westminster Gazette*, referring to the Maidstone typhoid-fever epidemic, says that very few villages in England have pure water, and to anybody who is acquainted with the facts it is not much wonder that typhoid and diphtheria are fairly constant items of village life. Many villages depend upon rivers for their supply, which the cottagers dip up in buckets as they want it, with all the possible contamination from other villages and land drainage up stream. Open wells and pits, choked with dead leaves and decaying vegetable matter, are frequent, and where there are covered wells and pumps they are often foul with the percolation of old cesspools and dead wells in their neighborhood. In Diss the supply comes from pits, and the surveyor reported that the water was only six inches deep and in a very bad state, with a foot of foul mud under it. It was suggested that the mud should be dredged up and the rainfall left to fill the pits again. The medical officer pointed out that the water in any case was utterly unfit for drinking-purposes, as it was contaminated by field drainage.

Starvation and Death in the Klondike.—The tales brought by returning miners are of terrible suffering and privation endured by the gold seekers who have gone to Alaska this year, and they give every reason to fear that the misery of this coming winter will beggar description. The members of a party that returned two weeks ago to Victoria gave a moving account of their return over the mountain trail from Dawson City. During the trip they were reduced to boiling and eating pieces of raw hide and their boot tops. At one time they had nothing for three days, when an owl was killed, and on this they subsisted for three days longer. When they reached Dalton's cabin two of the party were mad from hunger. The leader of the party said that when he left Dawson City four hundred persons had purchased tickets for St. Michael, intending to go down on the steamers, which will, however, not get up until spring releases the river ice. To add to the misery of their position, every day sees new arrivals. Now that they are there they find curses their welcome, and would give anything to escape. The supply of food is insufficient for those already there, and the only escape of many from starvation is through typhoid fever, which is reducing their number at the rate of five or six a day, and so leaving a smaller number of consumers of the lessening food supply.

The German Conquest of Moscow.—An English member of the Twelfth International Medical Congress writes (*The Practitioner*): "The congress was overspread by hordes of Austro-Germans. They waited in rows outside the doors before any reception, and then made a football rush for the buffet, where they remained in rows six deep for the remainder of the evening, on the *j'y suis, j'y reste* principle, not stirring even to let a lady get an ice. They were well organized; for months beforehand committees had been at work in Berlin and Vienna, the meetings being presided over by such men as Virchow and Politzer. The Teuton, therefore, was very much in evidence in every part of the congress, entirely owing to his own strategical forethought and disciplined 'pushfulness.' Nearly every German professor whose name is known outside his own lecture room was there. Like the old Highland chiefs when they went forth in state, each leader of German medicine came to Moscow 'with his tail on,' each one bringing with him a posse of admiring and dutiful retainers, who acted as a *claque*. The French were simply swallowed up in the whirlpool of triumphant Teutonism."

The Prince of Wales' Hospital Fund.—The receipts of this fund, up to date, amount to about £180,000, which is a goodly sum, but very far below that which was aimed at by those who put His Royal Highness in motion. To have realized their anticipations at least a million was wanted, but there is no hope that anything approaching that amount will come in. There are, in fact, abundant evidences that the London hospital system, as a means of relief of the poor, is on its last legs, and we may hope that these costly institutions will, sooner or later, find it necessary to make both ends meet by the wholesome process of retrenchment rather than the oft-repeated process of unblushing begging.—*Medical Press.*

"Virchow's Archiv."—This much quoted periodical celebrates with the appearance of volume cl. the completion of its fiftieth year of publication, it having been established in 1847.

A Decorated Surgeon.—Sir William MacCormac is said to be the most highly decorated member of his profession in Great Britain. He has the Order of Medjidie, the Crown of Prussia, the Ritter Kreuz of Bavaria, Dannebrog, Crown of Italy, Cross of the Takovo of Servia, Order of Merit of Spain and Portugal, and the Star of Sweden. He is also Knight of Grace of the Order of St. John of Jerusalem.

"The Journal of the Boston Society of the Medical Sciences" has been enlarged to octavo size, and will hereafter not be sent gratis to would-be readers. It will contain abstracts of experimental work carried on in the medical school of Harvard University, the experimental laboratories of the Massachusetts General and the Boston City hospitals, and the physiological and biological departments of the Massachusetts Institute of Technology and Clark University. It will be published ten times a year, from October to June, promptly after each meeting of the Boston Society of the Medical Sciences, of which it will contain full reports.

To Study Yellow Fever in Cuba.—A Washington dispatch states that the President has detailed passed Assistant Surgeon Eugene Wasdin and passed Assistant Surgeon H. D. Geddings, United States Marine Hospital service, for special duty at Havana, Cuba, for the purpose of making bacteriological investigations into the cause and nature of yellow fever. These officers have been engaged for some time in laboratory work in New Orleans, but as the yellow fever is dying out in the South it is deemed best that they should continue the investigation at a place where proper material may be obtained.

The Disinfection of Books.—At a recent meeting of the New York Library Club, Dr. John S. Billings described the method of disinfection of books by formalin vapor. In some experiments made recently at the laboratory of the University of Pennsylvania, a saucer of formalin, a book which had been infected with the bacteria of diphthéria, another with scarlet fever, and another with erysipelas, were placed under a bell jar. The experiment showed that one cubic centimetre of formalin to three hundred cubic centimetres of space would thoroughly disinfect any book in fifteen minutes.

Dr. Frederick G. Novy, of Ann Arbor, has been appointed a member of the Michigan State Board of health to fill the vacancy created by the resignation of Dr. G. H. Granger. Dr. Novy is well known for his excellent work in physiological chemistry, much of which has been done in collaboration with Dr. Vaughan, also of Ann Arbor.

A Russian Leprosy Congress.—Russian physicians are agitating the question of holding a national conference on leprosy in St. Petersburg. The conference will probably be held early in 1898, but the precise date is not yet determined upon.

Dr. Richard K. Macalester has been appointed neurologist to the Columbus Hospital of this city.

The "Right Lungs" and the "Left Lungs" are the names of two quoit teams organized among the consumptive patients of the Cincinnati Branch Hospital.

The Ninth International Congress of Hygiene and Demography will be held in Madrid in April, 1898. The following are the sections in the department of hygiene: 1. Microbiology applied to hygiene. 2. Prophylaxis of communicable diseases. 3. Medical climatology and topography. 4. Urban hygiene. 5. Hygiene of alimentation. 6. Hygiene of childhood and school life. 7. Hygiene of exercise and of labor. 8. Military and naval hygiene. 9. Civil and military veterinary hygiene. 10. Sanitary architecture and engineering. In the department of demography there will be three sections: 1. The technique of demographic statistics. 2. Statistical results and their applications to demography. 3. Dynamic demography.

Hospital Stamps.—The issue of a special stamp to be sold in aid of the Prince of Wales' Hospital Fund was so successful in its results this year that it has been decided to make it an annual institution. Philatelists throughout the world will have therefore to decide that these stamps are not worth collecting, or else submit to an annual tax for the benefit of the London hospitals.

Indigent Consumptives in the Orange Free State.—The president of the Bloemfontein Benevolent Society has written to the London *Times*, urging English medical practitioners not to send impecunious consumptives to the Orange Free State. Bloemfontein, he says, has a high and well-deserved reputation as a health resort for consumptives, but it is not a place in which invalids can hope to gain a livelihood. The population is under seven thousand, and quite three thousand out of that total are blacks. The trade of the town is not large, and living is very expensive. Phthisical persons are constantly arriving there, hoping to find some means of making a living, but find none, and soon see themselves reduced to living upon the bounty of the charitable. Similar complaints are heard from time to time in certain parts of our own

country. Next to sending a person in the last stage of pulmonary tuberculosis to die among strangers far from his home, the practice of sending those in the early stages to a new place without their previously being assured of a means of support is most reprehensible and cruel.

Association of Assistant Physicians of Hospitals for the Insane.—At the annual meeting of this society, held recently at Mendota, Wis., the following papers were presented: "Imbecility an Element in Insanity," Dr. R. M. Phelps; "A Case of Pure Cocainism," Dr. George Boody; "The Early Diagnosis of Paretic Dementia," Dr. V. Podstaka; "A Report of a Case of Tubercles of Brain, with Clinical History and Presentation of Gross and Microscopic Specimens," Dr. A. F. Lemke; "Staff Meetings in Hospitals for the Insane," Dr. Irwin H. Neff; "Report of the Ophthalmologist at Willard State Hospital, for One Year," Dr. S. F. Mellen; "Some Notes on Twenty-five Cases of Paresis," Dr. Samuel Dodds; "Alcohol as a Factor in Producing Insanity," Dr. M. C. Mackin; "A Classification Based on Clinical Lines, Combined with a Tabulation of Clinical Data," Dr. R. M. Phelps; "The Advantages of Cottages in the Treatment of Certain Cases," Dr. Samuel Dodds; "Report of an Autopsy, with Exhibition of Photographs," Dr. George Boody; "A Syphilitic Case, with Post-Mortem," Dr. Irwin H. Neff; "Relation of Laboratory Methods in Psychology to Asylums," Prof. W. O. Krohn, of Kankakee Hospital.

Public Charities in Washington.—The district commissioners will ask congress to appropriate $134,500 for the maintenance of the public hospitals and dispensaries in Washington. The largest item in the appropriation asked for is one of $57,500 for the Freedman's Hospital and Asylum.

Beriberi in the Isthmus.—Several hundred negroes were recently imported from Sierra Leone to work on the Panama Canal, to take the places of the Jamaicans, whose work had not been satisfactory. Soon after the arrival of the Africans, beriberi broke out and nearly one hundred of them have died of the disease.

New City Lungs.—The committee on small parks, appointed by Mayor Strong in June to advise concerning the creation of small parks in the city below Fifty-ninth Street, recently made a report. A number of sites were recommended, and it is estimated that all the proposed parks can be opened within four years, at a cost of about $3,500,000.

A Medical Counterfeiter.—A physician of Haralson County, Ga., was recently arrested on a charge of counterfeiting. His specialty was the manufacture of $10 gold pieces.

Smugglers of Drugs.—A young man in Rhode Island, the owner of a yacht, was recently punished for an attempt at smuggling. He took his yacht to Halifax, Nova Scotia, last summer, and while there purchased some $2,000 worth of sulphonal and phenacetin. These he brought to this country, and then found he could not dispose of them without detection. He finally became apprehensive that the authorities would find him out, so he went to the customs officer and confessed to having the drugs. These were confiscated, and the young man now has concluded that crime doesn't pay.

A Physician Accused of Grave Robbery.—A physician of Chillicothe, Ohio, was arrested recently, charged with complicity in grave robbery. He is accused of having directed two medical students to a cemetery where a body they wanted to steal had been buried, and then of carrying the disinterred body in his own trunk to the medical college in Columbus.

Newspaper Medicine.—The people of Omaha are itching, if we may believe the reports telegraphed to the daily papers of this city, and the physicians are said to be puzzled as to the nature of the affection. According to the dispatches, this "disease develops in small eruptions which cover the body. The eruptions are highly inflamed and finally scale off like scurvy." We may well believe that eruptions which "scale off like scurvy" puzzle the physicians, who state that "the disease is caused by some germ that settles on the skin," but "this is all they can say about it."

Poisonous Bullets in Cuba.—In defiance of the laws that govern civilized warfare, the Spaniards in Cuba, so the *Daily Chronicle's* special correspondent asserts, have been using brass-tipped cartridges throughout the Cuban war. These bullets become coated with verdigris, and when fired from a rifle the brass spreads out raggedly at the base, so that it creates a deadly wound. With a limited medical staff and an absence of antiseptics, such wounds lead to gangrene and death. In short, the bullets are, to all intents and purposes, poisonous, and contravene the Geneva convention. The recent capture of a train has placed a large quantity of this deadly ammunition in the hands of the insurgents, who are now enabled to hoist the Spaniards with their own petard. The nickel-covered bullet used by our own troops in the present Indian frontier war has caused such terrible wounds as to have suggested to certain unfriendly nations that we have adopted explosive bullets. The effect, however, is simply due to the ripping open of the nickel jacket on contact. In the case of the Spaniards no attempt is made by General Weyler to cloak the fact that he is waging a war of extermination, and that, in characteristic Spanish fashion, he considers any means justified that may conduce to that end.—*Medical Press.*

The Last Slap at the Expert Witness.—Experts are having a hard time now. Some can get no pay for their testimony, others are accused of ignorance, and others again of venality, but it was reserved for a St. Louis judge to recognize a "professor" of phrenology as an expert in insanity. He testified that the defendant in a murder trial was insane, and, upon being questioned as to the reasons for his conclusion, said that his opinion was based solely upon a phrenological examination made by passing his hands over the man's head.

A Jumble of Misinformation.—Under the caption "A Caution against American Medical Qualifications," our esteemed contemporary, the *Medical Press*, says: "It is understood that the American Association of Medical Colleges, which has been heretofore regarded as the select circle among the numerous diploma-granting institutions of the new world, has agreed to recognize the studies pursued in homœopathic and eclectic colleges for four years of the necessary period. This means practically an abrogation of the education test altogether, the merits of the candidate being henceforth determined by an examination of which no one knows the standard." The crass ignorance of foreigners concerning American institutions would be a matter of small concern to us if they did not presume to draw conclusions from their false premises.

Fining a Corpse.—A coroner in Kansas recently fined a corpse twenty-five dollars for carrying a concealed weapon. The latter was duly confiscated.

Obituary Notes.—Dr. James Carey Thomas died at Baltimore on November 9th, at the age of sixty-four years. He was graduated from Haverford College and later from the medical school of the University of Maryland in the class of 1854. He was a trustee of Johns Hopkins University. He was a widely known member of the Society of Friends.—Dr. E. A. Frampton, of New Plymouth, Ohio, died September 14th, of pulmonary trouble, aged almost fifty-nine years. He was a great sufferer for many years. He was graduated in medicine in 1869.—Dr. George Allen, superintendent of the State Hospital at Collins, N. Y., died in Gowanda on November 14th, of chronic nephritis, at the age of forty-four years.

The Yellow-Fever Visitation is practically at an end, although there are still a few cases reported daily in New Orleans. The United States Marine Hospital service will stop the disinfection of freight in a few days. Had it not been for this service all business, travel, and even the mails would have been stopped in the South and Southwest. The fever has finally been rooted out of the Jewish Home, Poydras Asylum, Orphans' Home, and other asylums which it invaded notwithstanding the effort to keep it out. All quarantine guards have been removed from houses, but the yellow-fever flags will be still kept up.

Obituary.

HARRISON ALLEN, M.D.

Dr. Harrison Allen, emeritus professor of comparative anatomy in the medical school of the University of Pennsylvania, died suddenly at his home in Philadelphia, on Sunday, November 14th, in an attack of angina pectoris. Dr. Allen was born in Philadelphia in 1841; was graduated in medicine from the University of Pennsylvania in 1861, and then passed a year as interne at the Blockley Almshouse. He entered the army upon completing his service at the Blockley, and was retired as surgeon with the brevet rank of major at the close of the war. In 1865 he was called to the chair of comparative anatomy and zoölogy in the medical school of the University of Pennsylvania, which he held for thirty years. He was the author of numerous monographs, papers, and books on medical subjects. At the Columbian exposition he was one of the judges on anthropology. He was a member of the Academy of Natural Sciences, the Natural History Society of Boston, the Pathological Society of Philadelphia, the Biological Society of Washington, the Philadelphia County Medical Society, the American Laryngological Association, the Neurological Society of Philadelphia, the Historical Society of Texas, and the American Association of Anatomy, of which he was one of the founders. He was visiting surgeon to the Philadelphia Hospital from 1874 to 1878, and was assistant surgeon to Will's Eye Hospital, 1860–70, and St. Joseph's Hospital, 1870–78. He was also professor of anatomy at the Philadelphia Dental College, 1866–78.

THOMAS WILLIAM EVANS, M.D., D.D.S.,

Dr. T. W. Evans, the "American dentist" of Paris, died at his home in that city, on Sunday, November 14th, of angina pectoris. He was born in Philadelphia about seventy-four years ago, the exact date being uncertain, as one of his peculiarities was a reticence concerning his age and he would never admit that he was growing old. He began life as a goldsmith's apprentice, and it was while making plates for artificial teeth that he first conceived the idea of adopting dentistry as a profession. He entered the Jefferson Medical College and took an M.D. degree there and then studied dental science. He went to Paris in 1846 to attend a conference as a representative of American dental surgery, and resolved to remain in that city, where he speedily achieved a great reputation. The president of the French Republic, afterward the Emperor Napoleon III., was among his earliest friends and patrons, and through his recommendation Dr. Evans soon numbered most of the crowned heads of Europe among his *clientèle*. He was instrumental in getting an introduction to a court ball for the Duchess of Montijo, who there met the Emperor and later became the Empress Eugénie. He again rendered a great service to the same lady by conveying her secretly out of Paris during the siege, and seeing her safely landed in England. Dr. Evans accumulated a large fortune by the practice of his profession and successful real-estate speculations, and he announced, when on a visit to this country a few months ago, that he intended to devote a large part of it to the foundation of a college of dentistry. His wife died some time ago and he left no children. Although the greater part of his life was spent in Paris, Dr. Evans always remained a patriotic American, and left directions that he should be buried on American soil. He came to the United States during the war of the rebellion, organized the National Sanitary Commission, made an investigation of the conditions here, and was instrumental in preventing Napoleon from granting recognition to the South. Dr. Evans assisted many struggling students in life and buried some poor ones or their wives when death came. He established the Lafayette Home in Paris for unchaperoned American young women who went to Paris to study. Although designed for his countrywomen particularly, the privileges of the home were extended to some other students. Altogether about one hundred could be accommodated in the home, and the demand was such that he caused the erection of another building, the opening of which was to have been celebrated on Christmas Day.

Society Reports.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, November 2, 1897.

C. A. HERTER, M.D., IN THE CHAIR.

Thomsen's Disease.—DR. GEORGE W. JACOBY exhibited a typical case of Thomsen's disease. The patient, a young man, had been referred to him by Dr. Schwinn, of West Virginia, with a correct diagnosis. The patient was twenty-eight years of age, and had lived in this country since 1884. There was nothing in the family history bearing upon the condition especially, except that a distant cousin was said to have walked stiffly and in a peculiar manner for fifteen years. The patient himself had always been delicate, but had been as active as other boys. He had had typhoid fever in 1889, and on recovering from this had first noticed a cramp in the legs. After a little it was found that he could not execute movements as quickly as before. In 1893 he first sought treatment. For the past year or two his arms and hands had also been affected. The condition varied considerably at different times, but was apparently not affected by meteorological changes. The examination showed quick reaction of the eye muscles, with spasm of the external rectus; cramp of the masseter muscles on bringing the jaws together forcibly; no involvement of the pterygoids. All the muscles of the upper extremity and of the thorax were involved; indeed, nearly all the muscles of the body. The contraction of the muscles was decidedly tetanic, and was very marked at first; but on repeated tests it gradually subsided. The electrical examination showed marked myotonic reaction, and also a wave-like appearance; but he could not make up his mind that this latter phenomenon consisted of a series of waves, such as are observed in water. A piece of muscle had been excised from the biceps and also one from the quadriceps, but they had not yet been minutely examined. The case was quite characteristic on account of the marked variations occurring from time to time. The speaker said that in an article published by him ten or more years ago, he had taken the stand that these cases were probably of myopathic origin, due to some congenital defect in development; but in the light of modern investigation he was now disposed to believe that some central cause was at work—that there was a functional hereditary derangement of the central nervous system—a condition of lessened resistance in the cells. This did not seem to him a strange assumption, when one considered the well-known idiosyncrasies exhibited to various toxic influences. On the theory that some kind of toxæmia was at the foundation of this disease, he thought the observed phenomena could be explained—at least, in this direction seemed to lie the possibility of solving the pathogeny of this class of cases. This patient had not been affected by the disease until eighteen years of age; hence there was no propriety in calling such a case "myotonia congenita." He would divide these cases into three classes, viz.: (1) myotonia congenita, (2) myotonia acquisita, and (3) myotonia transitoria.

DR. FREDERICK PETERSON asked why a theory of causation might not be founded upon chemical changes in the muscles. Changes in the structure of the muscles, he said, were known to arise; for instance, in connection with typhoid fever.

DR. HERTER thought that we must look to toxic agents as furnishing at least a clew to the causation of such conditions. The peculiar susceptibility to certain types of poisons, seen, for instance, in epilepsy, must be referred to peculiarities of the central nervous system. He would agree with Dr. Peterson that these cases did not seem to be of central origin, and that it was more probable that they arose from chemical changes in the muscles. To study this subject successfully, it would be necessary to inquire into the condition of the secretions and excretions at the time of the onset of the disease and not after it had become chronic.

Pachymeningitis Hemorrhagica Interna in Children.—Dr. C. A. Herter said that internal hemorrhagic pachymeningitis was usually considered to be a very rare condition in children, yet one German observer had found it in about seventeen per cent. of his autopsies. The following cases were reported:

CASE I.—A female child, five and one-half months old, was admitted to the Babies' Hospital on May 15, 1897, with an entirely negative family history. The child's illness had begun one month previously, with persistent vomiting. The head was of normal shape and the fontanelles were not bulging. There was a soft spot over one parietal bone. The child had no teeth. On the fifth day after admission tremor and nystagmus developed. Nine days after admission there was a general convulsion, in which the mouth deviated to the left. Cyanosis was a feature of the convulsion. A second one occurred in ten hours. After these seizures the fontanelles were sunken. The child now became semicomatose, and died after a few days.

The autopsy showed the presence of hemorrhagic pachymeningitis, fibrino-purulent pleurisy, pulmonary congestion, fatty liver, and nephritis. Along the superior longitudinal fissure, over the entire base and over the island of Reil on both sides, was a membrane covering the pia. The ventricles were normal in size and contained about one drachm of hemorrhagic fluid. There was fluid blood in all the sinuses. The cervical cord showed the same conditions. Under the microscope the right occipital region showed the pia attached to the cortex in many places, and there was a splitting up of the membrane overlying the cortex into two or more layers. The inner layer was infiltrated with small round cells. The outer membranous layers consisted of small round cells, fibroblasts, and connective-tissue fibres. The island of Reil showed the same condition, but much more marked, and about the same condition was present over the cerebellum. In the spinal cord there were only slight traces of hemorrhage.

CASE II. — Female infant, colored, twenty-two months old. The child had been nursed for seven months. It had never walked or stood alone, and was markedly rachitic. The first two months in the hospital were marked by slight loss in weight and considerable prostration. In October, 1897, the child was readmitted, with the statement that she had been well up to three days before, at which time she had had four convulsions, followed by three more the next day. The general condition was very bad. The hands and feet were in a position of persistent flexor contraction, characteristic of tetany. The knee jerks were unobtainable; the fontanelles were bulging. There was slight but varying rigidity of the muscles at the back of the neck. Bloody mucous diarrhœa was present, and the child died comatose.

The autopsy showed pachymeningitis hemorrhagica interna, broncho-pneumonia, and acute and chronic ulcerative colitis. Over the right side of the brain was a recent blood clot, covering the entire hemisphere, and over the left occipital lobe the inner surface of the dura was covered with a membrane extending from the superior longitudinal fissure on either side. The pia was congested. The ventricles and brain substance were apparently normal. All the sinuses were filled with recent clots. The microscopical ex-

amination showed thickening of the pia over the right temporo-sphenoidal lobe, and the vessels of the pia were thickened. There was also a thick membrane splitting up into layers, as in the other case. There were numerous small blood-vessels, and hemorrhages had occurred into the meshes of the membrane. In places there were aggregations of small round cells undergoing fragmentation. They were found chiefly in the superficial layers of the membrane. In the dura the fibres were separated from each other by serous infiltration, and the dura was covered with a membrane similar to that already described. In places there was very extensive pachymeningitis.

It was at about five months of age, the speaker said, that this disease was especially frequent. The majority of these infants were badly nourished, many of them being subjects of rachitis or of chronic colitis. The new membrane must be regarded as originating from proliferation of the dural endothelial cells. In some cases there was little inclination to hemorrhage. The membrane was very variable in thickness; sometimes it reached a thickness of two or three lines. It was especially prone to occur in the basal fossæ. There seemed no good reason for thinking that the locality of the pigmentation indicated that the layer of blood originated from the inner surface of the dura. On the other hand, there was no conclusive proof of the old notion that the disease was of inflammatory origin. It was so common to find severe intoxications without such lesions that the intoxication theory did not seem to him tenable. It was apparently impossible to recognize the condition until the hemorrhage occurred, and even then it was extremely difficult to make a positive diagnosis. Slight cerebral symptoms were probably masked in these very young and usually marantic children. The hemorrhage was probably more often unilateral, and the usual symptoms present were rigidity, hemorrhage, and coma. Paralysis was rarely noted. The pyrexia was usually less than in meningitis, but these cases were so commonly complicated with other diseases that the range of temperature was very variable. He did not think there was any symptom or combination of symptoms in hemorrhagic internal pachymeningitis which might not be encountered in any acute infection without any cerebral affection being present; but whenever unilateral rigidity and convulsions, with deepening stupor, were present in a cachectic or rachitic child under one year of age, we should think of that diagnosis. It was probable that relatively slight traumatisms of the head might occasion rupture of vessels in the highly vascular membrane. This gave these cases a certain medico-legal importance.

Dr. Peterson remarked that the condition was interesting to him because of the possibility of its being found occasionally in infantile cerebral palsy.

Dr. Herter said that he was inclined to think that these membranes were considerably more frequent than one would suppose from the literature. It was quite possible to overlook the presence of the membrane if it were not decidedly vascular.

The Pathology and Morbid Anatomy of Huntington's Chorea, with Remarks on the Development and Treatment of the Disease.—Dr. Joseph Collins said that the neurologist frequently encountered knotty problems, and among these none had the secret of its genesis more carefully concealed than the hereditary degenerative diseases. The pathogenesis of the acute inflammatory diseases of the nervous system was an open book, but the degenerative diseases were discouragingly slow in yielding the mystery of their being. This was especially true of such degenerative diseases as the hereditary ataxias, choreas, and dystrophies. The status of the original lesion could not always be inferred from a consideration of the lesion found at the time of death, and this was particularly true if the disease had existed a great number of years. No one could do much laboratory work on the central nervous system of individuals who had succumbed to degenerative nervous diseases of long duration, without having forced upon him the fact that there are certain abnormalities of the circulatory system—varying degrees of degeneration of vessels, change in the size of the lymph spaces, and relative disproportion of glia tissue to the parenchyma—which occur with all degenerative diseases, considered entirely apart from their causation. He felt convinced that such changes were very often secondary, and had no other significance than as evidences of protracted disturbance of nutrition, and that this nutritional depravity was the result of the existence of the original lesion. There was nothing more certain than the occurrence of glia proliferation in all slowly progressing destructive lesions of the nervous system, but nothing could be more misleading than to consider this glia overgrowth to be primary and the changes in the parenchyma secondary.

Huntington's chorea, Dr. Collins said, was a comparatively rare disease and of rather recent recognition; hence the reports made upon its pathology had not been uniform. The discrepancies were apparently the resultant of the varying points of view of different observers. In studying the nervous system in cases of Huntington's chorea, it was scarcely justifiable to maintain that all the morbid conditions were inherent to the disease, for, as has been said, many of them might be the consequence of prolonged interference with nutrition. Although the present study of the pathology of the disease was upon an individual who had had the disease for a considerable time, it was compared with a case of much shorter duration reported by Dr. C. L. Dana. A study of these two cases, he felt confident, would go far toward establishing the morbid anatomy and hinting at the pathogenesis.

His patient was a man, fifty-five years of age, who had married in early manhood, and who was the father of three children—all of them giving evidence of neuropathic inheritance. The known duration of the disease in his case was ten years. At the beginning the hands only were affected, but in the last years the lower extremities were also involved. The mind remained in fairly good condition up to about three years before his death, when he began to have suspicions about his relatives and friends, and became forgetful and suicidal. His speech was so imperfect that in the last years of his life he was understood with difficulty. Dr. Collins had seen him for the first time a few days before his death. He then had a temperature of 105° F., and it remained at about this point until the end. The movements were very severe and incessant, except during sound sleep, although even then they frequently awakened him. He was quite conscious, but made no response to questions. The cause of death seemed to be exhaustion and high temperature. The disease was traceable to the maternal grandfather—an Irishman—who had three children, two of whom were affected with the disease. One of these was the mother of this patient, and of her seven children five were afflicted with the disease. The other daughter had two children, one of whom became choreic. In three generations there had been no less than nine affected, and, when it was considered that many of these children died in infancy, the number of cases that had developed was surprisingly great.

At the autopsy, on opening the skull, the dura was considerably adherent, the diploe dense, and the Pacchionian depressions were marked. The brain had a wet appearance, as did also the cord. The pia was not adherent to the brain. The convolutions of the anterior pole of the brain were very small, and the entire encephalon weighed forty-three and one-half ounces.

The dura was intimately adherent to the spinal column. The principal fissures were somewhat wider and shallower and shorter than in the normal brain, but there was nothing pointing to defective convolutions. The average thickness of the gray matter was uniformly less than in the normal brain cortex, but this thinness could not be attributed here to age. An examination of the pons and medulla oblongata did not show any marked variations from the normal, but the changes were more noticeable lower down. Microscopical changes were not confined exclusively to the Rolandic region, but the process here was more advanced. The specimens were stained by various methods and carefully examined. The macroscopical changes were briefly as follows: 1. Thinness and atrophy of the cortex. 2. The mottled, streaked appearance and cribriform state on cross-section of the brain in the fresh state, due to diminution in number and in health of the ganglion cells, and to the increased perivascular and pericellular spaces and increased patency of blood-vessels. The microscopical changes were: 1. A decay or slowly progressive degeneration of the ganglion cells of the cortex throughout the brain, especially of the two deepest layers, the layers of large pyramids and polymorphous cells. This cell death was particularly evident in the Rolandic region, very much less so in the anterior pole of the brain, and incomparably less in the posterior pole. 2. Increase of glia tissue, but not sufficiently prominent to constitute sclerosis, the conspicuous increase being about blood-vessels and ganglion cells. 3. Enlargement of the pericellular spaces and distention of the pericellular spaces. 4. Slightly diseased blood-vessels, consisting principally of a proliferation of the nuclei of the adventitia and a thickening of the intima. This involvement of the vessels was not regular or symmetrical, but showed itself in certain sections of vessels only. 5. Relative paucity of the medullated fibres of the cortex. In short, it might be said that the lesion was a chronic parenchymatous degeneration of the cortex, with consecutive and secondary changes in the interstices, the brunt of the disease having been borne by the motor regions. There was, in consequence, a degeneration of the pyramidal tracts in the spinal cord. In Dr. Dana's case the central convolutions suffered most, and the process occurred in patches throughout the affected cortex. There was nothing to justify the opinion that it was an inflammation; the process was evidently one of degeneration.

In connection with the treatment, Dr. Collins said that he desired to emphasize the necessity for delaying the advent of the disease in those who had a hereditary tendency to it, and also to emphasize the folly of tenotomy of the eye muscles—a method of treatment now being carried out upon one of these unfortunate individuals in this city, with a promise of a cure. If we wished to influence the course of hereditary chorea after it had once become manifest, it would be necessary to administer in the largest possible doses consistent with life whatever drug was selected, and to maintain this medication for a long time.

Dr. Onuf said that he had been present at the autopsy in the case reported in the paper, and had been especially impressed with the general narrowing of the gyri—a general atrophy. On section, the mottled appearance of the cortex had been most striking, but the cribriform appearance produced by the enlargement of the perivascular spaces was also worthy of note. The general appearance of the brain resembled very closely that of a brain from a case of general paresis. The microscope confirmed the macroscopical appearances, although the changes were not so marked as one would have expected from the gross appearance. The cell changes were of the atrophic order. The characteristic feature was the accumulation of neuroglia cells in the pericellular and perivascular spaces. His impression was that this accumulation was due to a secondary process following atrophy of the cells. The disease was evidently a degenerative one, originating in the parenchyma of the brain, and not in the interstitial tissue.

NEW YORK MEDICO-CHIRURGICAL SOCIETY.

Annual Meeting, November 2, 1897.

J. Blake White, M.D., President.

A Plea for Rational Therapeutics in Diphtheria.—Dr. A. E. Bieser read a paper with this title. He said that a proper working hypothesis could not be based on either bacteriology, pathology, or etiology alone, but upon a sensible combination of all three; and until such a hypothesis was formulated no investigation of diphtheria could be said to be exactly scientific. The diphtheria bacillus might be the specific cause of what was known as Klebs-Loeffler infection, but it certainly was not the cause of the physiological inflammation of the throat which furnished that point of least resistance which was absolutely necessary for the development of the bacillus and its toxin.

The Specific Nature of Diphtheria.—In the first place the Klebs-Loeffler bacilli did not affect the healthy throat, because of the absence of a nidus of development, whatever that might be. That a perversion of normal physiology was necessary to start up the Klebs-Loeffler bacillus was generally admitted; hence this bacillus could not cause the disease, and it was perfectly reasonable to believe that any treatment that restored or partially restored the perverted function might do as much good as a specific plan of medication, such as that with antitoxin. It was known that healthy secretions were capable of disposing of even pathogenic bacteria, and bacteriologists admitted that the healthy throat was in itself a barrier against the invasion of the Klebs-Loeffler bacillus. If this was true, our effort should not be to get rid of the disease by the use of diphtheria antitoxin and germicides, but by stimulating the normal secretions and so favoring the removal of the pathogenic germs. Numerous cases of clinical diphtheria had been reported by competent observers in which Klebs-Loeffler bacilli were absent—cases which were diphtheritic in every respect, even to the extent of causing paralysis and death. Indeed, Loeffler himself had stated that there could be true clinical diphtheria without the presence of Klebs-Loeffler bacilli. Jacobi, in 1895, had stated that he doubted if there might not be such a thing as a streptococcus diphtheria, and Bowker in the same year had said that the streptococcus infection associated with diphtheria was just as virulent as the infection with the Klebs-Loeffler bacilli. It had seemed to him that, just as in tuberculosis, we had a distinct disease to treat independently of the bacillary or non-bacillary infections which modify the progress of the disease, so in diphtheria, independently of specific infection, there was a distinct physiological disturbance antedating, as well as following, the infection. If the specific hypothesis were not in accord with all the facts, how could a specific plan of medication, based upon such a hypothesis, meet all the requirements of the bedside treatment of diphtheria? Antitoxin might overcome the specific toxæmia, but it was not inconceivable that at the same time the physiological processes might be so interfered with as in itself to constitute a danger. A case was cited in which the patient was treated with antitoxin and recovered from the diphtheria, but died of nephritis originating, as it seemed to him, from the introduction of the specific remedy into the system.

A Dual Working Hypothesis.—He based his treatment upon a dual hypothesis, as opposed to the specific or bacteriological one. This hypothesis comprised two entirely different parts, viz.: (1) the numerous and varied perversions of physiological functions, called "the disease;" and (2) the Klebs-Loeffler infection and the other infections. It was important to remember that about the time the physician was called in to treat diphtheria it might be something more than a Klebs-Loeffler infection—the lungs, kidneys, and blood might be already infected with streptococci. In addition to the pathological lesion in the throat, the kidneys might be the seat of cloudy swelling or fatty metamorphosis, and the disturbances of the vital functions might be so great that all the antitoxin in the world would not cure the disease, though it might cure the Klebs-Loeffler infection.

Treatment.—He was not one of those who believed that when one had injected antitoxin diphtheria had been treated and that there was nothing else to be done. In some cases of diphtheria, especially in mixed infections, and when the renal function was already impaired, it would be far better if the injection of antitoxin was entirely dispensed with. The particular patient must be treated rather than the infection. As healthy secretions inhibited bacterial invasion, our effort should be to stimulate this action of the secretions. Three remedies seemed to act in this way, viz.: (1) ipecac; (2) iron; and (3) mercury. Ipecac increased the activity of the secretions, and iron removed the congestion in the throat and so favored normal secretion; but his sheet anchor was mercury. In his experience, this drug, in combination with whiskey and iron, had cured any Klebs-Loeffler toxæmia that the antitoxin could cure, provided it was given early enough and in sufficient doses. He did not give it as a germicide, but because it was one of the best glandular stimulants of the epithelial structures at our command. It was also a powerful hepatic stimulant, and a most excellent diuretic. In his hands, it had yielded better results in the same class of cases than had antitoxin. In cases of mixed infection, in which after the antitoxin injection the renal function had been entirely in abeyance, or this already impaired renal function had been still further interfered with, this treatment had caused a free action of the kidneys, in marked contrast to what was observed in cases in which antitoxin alone had been used.

Author's Statistics.—Of 33 cases treated in tenement practice without antitoxin, the Klebs-Loeffler bacilli were found in 80 per cent., and all but two were fatal. The two fatal cases had not been seen until the disease had lasted for a number of days, and they terminated in from seven to fourteen days later. He had treated in private practice a total of 115 cases of diphtheria, with 6 deaths, or a mortality of about 5 per cent. Of these 115, 104 were non-laryngeal, and of these 3 were fatal, giving a mortality of 3 per cent. There were 11 cases of laryngeal diphtheria, with 3 deaths, or a mortality of 27 per cent. Of the 115, 70 cases should have recovered under any rational treatment, as the croupous inflammation was not accompanied by a deep ulcerative process. Twenty-nine cases were severe, a deep ulcer being left after the membrane had come off. Five were septic nasopharyngeal diphtherias. The eleven laryngeal cases required intubation. The cases reported were all clinical diphtheria, yet under his treatment the mortality had been only 5 per cent. without antitoxin. His results corresponded well with those of Dr. Jacobi and Dr. Fruitnight. His treatment consisted in giving one-forty-eighth to one-thirty-second of a grain of bichloride of mercury every hour, day and night, for forty-eight hours, and then every two or three hours for two or three days more. Five minims of the tincture of the chloride of iron was given in the same way as the bichloride, only fifteen minutes later, and continued somewhat longer. By the fourth day the desired effect from the bichloride of mercury would be produced, *i.e.*, very slight salivation. Half an hour after the ingestion of the iron, two drachms of whiskey was given, diluted with water, and this was also kept up hourly. With this tripod of drugs he had succeeded in saving ninety-seven per cent. of the laryngeal and seventy-two per cent. of the pharyngeal cases. In the laryngeal cases it had been his practice to give forty grains of calomel by sublimation, every two or three hours. This he considered to be the treatment of the disturbance of throat physiology.

Gives Mercury and Whiskey up to the Physiological Effect.—As regards the treatment of the other conditions present, of course absolute rest must be insisted upon. Half an ounce to four ounces of whiskey should be given daily, the dose being doubled even if the pulse remained weak. The whiskey must be given until the physiological effect was obtained—flushing of the cheeks, odor of alcohol on the breath, and the desired effect on the pulse—no matter what the dose, but it must be given well diluted with water or milk to prevent its emetic action. Children stand large doses of alcohol, as they do mercury, in diphtheria. In older children affected with nasal diphtheria it might be wise to irrigate the throat with decinormal salt solution, but in younger children, who would always resist, such treatment did more harm than good. The abstinence from injudicious local treatment of the nose and throat had had a great influence in diminishing the absolute death rate from diphtheria in regions where antitoxin was now employed. Such abstinence would reduce the absolute mortality from diphtheria anywhere, irrespective of the use of diphtheria antitoxin. In order to combat the Klebs-Loeffler infection, if the case was seen early enough, antitoxin might be administered, but if not seen until the sixth or seventh day, and especially if there was marked sepsis or marked impairment of the renal function, he would not use it. These cases usually had suppression of urine, and terminated fatally, although perhaps this was not due to the antitoxin. In five cases of badly septic nasopharyngeal diphtheria the treatment above outlined saved two, although both had been declared by consultants to be hopeless. In the one hundred and fifteen cases there was not a single instance of mercurial poisoning; on the contrary, he had had the greatest difficulty in salivating these children. The most that he could do was slightly to increase the salivary secretion after two or three days, and this increase would disappear in twenty-four hours or so. There was no swelling, tenderness of the gums, or loosening of the teeth.

Proof of Specific Nature of Diphtheria.—Dr. William H. Thomson said that the paper was an illustration of how endless might be the discussions brought out by this subject of diphtheria. The word "specific" as applied to disease could be used correctly only in infections. It was difficult to think of a specific disease that was not an infection. He had been deeply interested in the specific nature of infectious diseases from the very beginning of his medical career, and the second medical paper that he had published had been on "The Distinction between a Virus and a Poison." In this he had directed attention to the fact that the action of a poison necessarily depended upon quantity, whereas with a virus, although quantity was not an essential element, a certain time, called the period of incubation, or, better, "germination," was required for the development of the characteristic symptoms. Another element of infection was reproduction—a process which could not be ex-

plained either physically or chemically—and which was observed only in the animal kingdom. At the time that he had presented to the County Medical Society the communication referred to, it had been met with a howl of derision, and for years he had been ridiculed for teaching that these communicable diseases were dependent upon organic agents. His especial reason for believing this doctrine was their markedly specific character.

The Characteristic Pathological Lesions of Diphtheria.—By "specific" was meant that a disease which was communicable could, in an infected subject, produce exactly the same disease in its clinical features in a healthy subject when communicated to him, and that the pathological changes would be identical. He did not think any one now would question that this was true of diphtheria. From the diphtheritic membrane a poison could be isolated which, when injected into animals, produced identical changes of a most characteristic and specific kind. These changes consisted in a very peculiar and specific form of fatty degeneration of the heart, and a peculiar change in the skeletal muscles, not at all resembling the fatty change observed in other diseased conditions of the skeletal muscles. Perhaps the most notable and characteristic changes were those occurring in the nervous system—a true solution of the axis cylinder, beginning in the medulla and ending in a breaking of the axis cylinder, with a typical Wallerian degeneration in the parts beyond. This degeneration was certainly specific, and was produced by the poison isolated from the diphtheritic membrane. Again, there were some peculiar hyaline changes occurring in small spots in the substance of the liver, and without any nephritis whatever there were similar and characteristic changes occurring in the parenchyma of the kidneys. These changes were, therefore, all specific. This being the case, we must admit that there is such a thing as specific diphtheria, due to a specific agent, namely, a bacterium which, outside of the body, upon plates and liquid cultures, could be propagated and made to produce the same specific results. If he had understood the paper correctly, the position taken by the author was that something besides the presence of the specific bacillus was necessary before we could have the disease diphtheria. He did not think any one would oppose such a statement. Wherever we had a seed, we did not necessarily have a crop, but when we had the crop we had the seed; in addition to the seed we must have the soil, otherwise we could not get the crop. Such a principle was exemplified in numerous instances throughout all nature—indeed, this was a strong argument against these diseases being due to ordinary poisons, for surely if such a poison was administered there would be a definite relation between the size of the dose and the result. Again, he had never seen a turnip turn into a potato, or *vice versa*, but he had seen fields in which, along with the potatoes or turnips, there were all sorts of weeds. In every one of the infections we sooner or later got multiple infections, and the disorders dependent upon them. There was, therefore, nothing remarkable about true septicæmia developing in conjunction with diphtheria; it was no argument against the specific nature of diphtheria. In pneumonia, for example, we had not only a specific infection but an invasion with a host of micro-organisms. All this simply meant that we must be constantly on the lookout for infections or complications other than the specific one first demanding our attention. It was for this reason that the skilful physician was he who could recognize not only the special action but also these collateral and frequently fatal complications arising from other causes.

Diphtheria Antitoxin.—He believed there was a true specific remedy for the specific infection of diphtheria, but his recognition of this served only to perpare him for all sorts of failures. One might just as well say that water had no specific power to put out fire, because houses sometimes burn down during a heavy downpour of rain. He had understood the reader of the paper to say that there were a number of cases of clinical diphtheria without the presence of the specific diphtheria bacillus. Certainly, it was well known that membranous exudation was a feature of various diseased conditions besides true diphtheria, and it was just for this reason that so much stress was laid upon the necessity for establishing the diagnosis of diphtheria by bacteriological examination. But he would take issue with the reader of the paper on the statement that the changes in the nervous system, characteristic of diphtheria, could occur in cases in which there had been no infection with the Klebs-Loeffler bacilli. There were cases of neuritis occurring with other infections, but these were not at all like the acute process of nerve degeneration found in cases of infection with Klebs-Loeffler bacilli.

Dr. Dillon Brown said that he certainly could not accept the conclusions drawn by the reader of the paper, although many of the facts stated were so well known and so generally accepted as to be considered almost elementary. The result obtained by Dr. Biesser in ordinary nasal diphtheria represented about the usual results that had been obtained by practitioners under this line of treatment before the introduction of antitoxin, and if Dr. Bieser had used antitoxin in proper doses in these cases it was probable that his results would have been much better. Dr. Brown said that in the laryngeal cases Dr. Bieser had certainly had better results than he had obtained with the same line of treatment, but such a very small number of cases was of very little account as indicating the value of any plan of treatment. His own experience comprised considerably more than one thousand cases, and if the results were divided up into hundreds, according to the different methods of treatment adopted, the results would vary more than fifteen or twenty per cent. Previous to antitoxin, and with the internal use of mercury, either in the form of bichloride or calomel, his results had not been nearly so good as those of Dr. Bieser—only forty to forty-five per cent. Since the use of antitoxin they had been very much better.

Mercury Rarely Causes Salivation in Children.—It was not surprising that the reader of the paper should not have produced salivation by such large doses of mercury, for children were not easily affected in this way by mercury; instead, this drug usually made them intensely anæmic and caused extreme prostration. In his own experience he had rarely seen salivation, but he had observed under this treatment intense anæmia and great prostration. In conclusion, he would enter his protest against a line of treatment like that advocated in the paper, which kept a baby awake day and night for forty-eight hours. Remarkably good results would have to be shown to justify such a course.

Faith in Antitoxin Still Weak.—Dr. William Henry Porter said that he was very decidedly in accord with Dr. Thomson in his assertion that diphtheria is a specific disease, and that it has a specific poison, producing specific changes. He had not yet been able to acquire so large a faith in the antitoxin treatment of diphtheria as some had done. In following the discussion it had occurred to him that the probability was that if antitoxin was the specific it was claimed to be it was only for a particular kind of infection; and, although it might be an agent for good in that particular instance, it might be very harmful to an individual in health or one with a mixed infection. He thought he had seen very unpleasant results from the use of antitoxin in cases which were not

diphtheria, or which were very mild examples of this disease. It was for this reason that he felt still somewhat doubtful as to how great a specific antitoxin was for diphtheria. He had no doubt that antitoxin was a chemical compound in the same sense that strychnine, atropine, morphine, etc., were, and it might, when introduced into the system, by its very toxicity stimulate the protoplasm into increased activity, but the question in his mind was whether it could do this with absolute safety.

Bromine the Best Local Application.—Dr. W. H. McEnroe said that he knew of nothing better than Smith's solution of bromine for the destruction of the horrible odor caused by decaying diphtheritic membrane in the throat. This remedy could also be given internally. He had never lost a case of diphtheria treated in this way. He relied upon iron in this disease, simply as a cardiac stimulant, and when it was given in drachm doses with sufficient frequency it would sometimes cause a return of the first sound of the heart. He had not used antitoxin very extensively, but from the testimony of others he was convinced that it approached very closely to a real specific.

Immunization.—Dr. S. A. Knopf said that nothing had been said in this discussion about the use of antitoxin as a prophylactic. In a recently published report of a severe epidemic of diphtheria in Bologna, isolation, disinfection, and closure of the schools had failed to stop the epidemic. Preventive inoculations of antitoxin had then been used on a large scale, four-fifths of the children between the ages of one and twelve being subjected to the treatment. At once new cases failed to develop, and the epidemic was quickly brought to an end. While in Paris he had watched with intense interest the first experience with diphtheria antitoxin. From his notes made at that time he found that, whereas the mortality from diphtheria in one hospital for the period from 1890 to 1894 had been seventy-three per cent., it fell to forty-nine per cent. in the first few months after the introduction of the antitoxin treatment. This should convince any one that it is really a specific in the treatment of diphtheria.

Dr. William Vissman said that he heartily agreed with Dr. Thomson as to the very great rarity of a pure infection of any sort, and he also believed that if antitoxin was mixed with the toxins of diphtheria and injected into an animal the animal would not die from a large dose of the toxins of diphtheria. He would also grant that if a certain quantity of diphtheria antitoxin was introduced into a lower animal, and after twelve hours the toxins of diphtheria were introduced, the animal would probably recover. If, however, a fatal dose of toxin was introduced, and then after twelve hours the antitoxin was given, the animal would not always recover. In other words, the diphtheria antitoxin seemed to be an antidote for the specific toxins of the Klebs-Loeffler bacillus.

Impossible to Make a Reliable Bacteriological Diagnosis of Diphtheria in Twenty-Four Hours.—It was customary now to make diagnoses of diphtheria in twenty-four hours by a bacteriological examination, yet in the first few hours the Klebs-Loeffler bacillus looked exactly like the xerosis bacillus—an absolutely harmless organism. Then there was an organism called the pseudo-diphtheria bacillus, which resembled it in every way, except that it was not toxic. We might take the diphtheria bacillus in its most virulent form, and put it in an incubator and grow it at about 45° C.; this would make an excellent demonstration of diphtheria in the laboratory, but it would be found to have lost its virulence at that temperature. We knew of no method by which this virulence could be reproduced. It could not be said that one had diphtheria unless there was present a diphtheritic lesion in the throat; the simple presence of the diphtheria bacillus in the throat did not constitute clinical diphtheria. Considering the many obstacles to be overcome in connection with the determination of the virulence and the establishment of the identity of the diphtheria bacillus, he did not hesitate to assert that a bacteriological diagnosis of virulent diphtheria in the human throat could not be made in twenty-four hours. It should be remembered also that about four hundred different organisms had been isolated from the throats of healthy persons, and that many organisms from the mouth, if cultivated in bouillon, would produce death in the lower animals in a short time, although perhaps not quite so quickly as the diphtheria bacillus. When one said that an organism was the cause of a disease, one must find that organism in every case of the disease; one must obtain a pure culture of this organism and with it reproduce the disease. Now the only thing that had been done so far with the diphtheria bacillus was to obtain it in pure culture.

Diphtheria in the Lower Animals.—The lesions found in human beings suffering from diphtheria were not the same as in the lower animals. If diphtheria bacilli were placed on the mucous membrane of one of the lower animals, there would be few if any symptoms; but if the mucous membrane was denuded and the bacilli were then applied to it, a false membrane would be formed, but it would not extend beyond the denuded surface. Sometimes by the injection of the diphtheria bacilli the membrane would be made to spread farther. If these animals lived long enough, they would suffer from paralyses, and this would occur even when they were inoculated with almost any other organism. If the diphtheria bacillus was injected into the subcutaneous tissue, the animal would die; if the fatal termination was postponed for some time, there would be first an infiltration at the site of the injection, and then a slight hydrops of the pericardium, pleura, and peritoneum. These were not characteristic of diphtheria in the human being. It would also be found that there was cloudy swelling of the muscles, kidneys, liver, and other organs; but the same was true of almost any infectious disease. If the animal lived sufficiently long, necrosis would occur at the site of the injection, but no one had yet been willing to place himself on record as saying that the bacilli so introduced in the lower animals had increased at all in number. Dr. Vissman said that he did not think that the diphtheria produced in the lower animals was exactly the same disease as that found in the human being. Kittens, young chickens, and dogs sometimes die of a disease presenting the usual clinical features of diphtheria—*e.g.*, diphtheritic membrane and paralyses—but the bacillus present here and capable of reproducing the disease was unlike the diphtheria bacillus. In diphtheritic inflammations of the conjunctiva we rarely found diphtheria bacilli, and the same was true in most cases of diphtheritic otitis. If a person had a slight ulceration in the throat, and a twenty-four-hour diagnosis showed diphtheria bacilli, the conclusion would be that the case was one of true diphtheria. It was on such diagnoses that many cases were reported as having been cured of diphtheria by the use of antitoxin.

Effects of Micro-Organisms on One Another.—Dr. Vissman next considered the effects of the micro-organisms on one another. He said that if the bacillus butyricus, a strictly anaerobic organism, was used to inoculate a tube, and at the same time the bacillus prodigiosus was added, it would be found that the bacillus butyricus would grow perfectly in the presence of the atmosphere. Similarly the bacillus of tetanus would not grow in the presence of the atmosphere unless the bouillon were at the same time inoculated with the diphtheria bacillus. Again, the diph-

theria toxin became less virulent when mixed with the staphylococcus pyogenes aureus, and very much more virulent when mixed with the streptococcus. Clinically, he said, it would be found that diphtheria was never a pure infection with the Klebs-Loeffler bacillus; it was most commonly contaminated with the streptococcus, which, as had been said, tended greatly to increase the virulence of the diphtheria bacilli.

In conclusion, he suggested that in the use of diphtheria antitoxin it was well not to lose sight of the effect of the injection of heterogeneous serum into the human system.

Antitoxin Treatment Not Free from Danger.—Dr. George Bieser said that at first he had been enthusiastically in favor of diphtheria antitoxin, but he had soon learned that his patients developed acute suppression of urine shortly after the administration of this remedy. This dangerous complication had developed in mild, ordinary cases of diphtheria, which, according to his past experience, should have recovered under very simple treatment. Recently he had used simple remedies, like benzoate of sodium and bromide of potassium, and just such cases had recovered. In the severer cases of diphtheria he had found the antitoxin of no value at all—in fact, the children had become much worse after its use. He thought the cases treated very recently here were not nearly so severe as those seen a few years ago. He saw no reason why we should run the risk of injecting a remedy of unknown properties in the mild cases, that usually recovered under simple and absolutely safe treatment.

Dr. Cook said that he had heard it claimed that diphtheria antitoxin produced its results by introducing into the system a substance which nature would produce, provided the individual lived long enough. If this was the correct theory of its action, he would raise the question: "Is it rational to introduce into the system at one time such large quantities of a substance that nature would only produce slowly and in small quantity?"

Dr. A. E. Bieser, in closing the discussion, said he had endeavored to make it understood that he believed the clinical disease diphtheria was due to a combination of germs, although undoubtedly one form was due to the Klebs-Loeffler bacillus. When there were present marked prostration, irregular temperature, croupous inflammation, and necrosis, the case was one of clinical diphtheria, no matter what the germ causing it. The point he had made was that diphtheria antitoxin was good for nothing else but pure Klebs-Loeffler infection, and that death was very commonly due to other germ infections. When a person died from a large dose of morphine, he died from the poison morphine, and not of the morphine disease, and so it might be claimed that permanganate of potassium would be useful for the morphine poisoning, but it would be of no advantage for the morphine disease. If in actual practice diphtheria was the diphtheria of the laboratory—a pure Klebs-Loeffler infection—then the statistics should show this; but Fränkel and many other authorities admitted that it rarely was such an infection. He had counted up the number of deaths occurring weekly in 1895, 1896, and 1897. Coming to the first week of November in each of these years, it would be found that in 1895, when antitoxin had been very little used, 8,270 cases had been reported (taken from the Medical Record), with 1,390 deaths: that in 1896, 9,550 cases had been reported, with 1,366 deaths—an increase of over a thousand cases; and that in 1897, 9,550 cases had been reported—200 less than in 1896—and 1,408 deaths. There were three potent reasons why, independently of treatment, the gross mortality of diphtheria should fall anywhere, viz.: (1) A definite set of cases, diagnosticated by the finding of the Klebs-Loeffler bacillus, received a definite dose of antitoxin, and these cases treated in a definite way were compared with indefinite cases in which the diagnosis was uncertain, and which had been treated indifferently; (2) the abstinence from injudicious local treatment would reduce the gross mortality; and (3) the undoubted increase in the number of mild cases reported, thus increasing the chances of a better percentage of mortality.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DEATH OF PRINCESS MARY, DUCHESS OF TECK—TYPHOID OUTBREAKS, MAIDSTONE, LYNN, BELFAST, CLIFTON—COUNCILLORS NEW AND OLD, PROFESSOR HORSLEY, DR. GLOVER — PATHOLOGICAL SOCIETY — PROFESSOR COATS—PROFESSOR MACEWEN—DEATH OF DR. BELL FLETCHER.

London, October 27, 1897.

The bereavement of the royal family, of which you will have heard, is shared by the nation, and mourning will be generally put on for the Duchess of Teck. Her royal highness was a great favorite with the public, and the medical profession will be specially sympathetic on account of the active part she took in promoting charities. There was much anxiety about her in April when Mr. Herbert Allingham operated for umbilical hernia. She recovered well and received an enthusiastic welcome at the jubilee. On Tuesday signs of a fresh obstruction occurred, and operation showed this near the old sac. The operation was successful, but the patient sank two hours later from heart failure. The duchess had had cardiac trouble for several years.

Mr. Herbert Allingham, F.R.C.S., is the son of Mr. William Allingham, and has followed his father's specialty and assisted in the last edition of his work on "Diseases of the Rectum." He has written a work himself on colotomy, which has been well received, and at the last vacancy was elected assistant surgeon to St. George's Hospital.

Typhoid fever is still the most prominent medical topic, fresh outbreaks having increased the public alarm. The number of notifications has diminished during the week. Yesterday there were 9, and that number has not been exceeded since the 21st. On the 25th there was only 1, but the next day there were 8. Up to last night the total number attacked reached 1,757 and the deaths 116. Some of the later cases are considered to be caused by direct infection from the sick, and it is asserted that in some parts the drains are so arranged as to be a danger. The fact that one-third of the houses have not an efficient water supply is quite as important. Dr. Washbourn's bacteriological examination enables him to state that the Tutsham spring was undoubtedly polluted, and there is a strong suspicion as to some other springs which it would be well to have him investigate.

The epidemic at Belfast is reported to be of mild type, but the number of cases is serious and points to a wide distribution. Water again is supposed to be the medium of the poison. There were 142 cases under treatment in the workhouse last week, and 26 fresh cases have been admitted. Altogether more than 350 cases are reported to have occurred in the city during the last month.

There is another serious epidemic at King's Lynn, Norfolk, which at the last census had a population of 18,360. Yesterday there were 25 new cases, bringing the total up to 235. Only 4 deaths have been reported

at present, but more will doubtless follow, though the type is said to be mild.

Here, too, the water supply is impugned, and if all I hear about it is true the epidemic is considerably overdue. New works are in progress to obtain a purer supply, but months must lapse before the completion. The delay is said to have been due to opposition to the scheme from some of the rate payers, but for which the new supply would have been in use by this time.

Yet another outbreak—Clifton near Bristol, 25 cases occurring in the week. In Clifton College there are, I hear to-day, 30 scholars and one of the masters down with typhoid. The outbreak is thought to be traceable to the milk supply.

The outbreak at University College Hospital was stopped at once, but one nurse has succumbed to the disease. As soon as inspection was made, a part of the water was suspected and immediately cut off. Further examination showed how correct was the suspicion. If the same measures had been taken at Maidstone, how many lives would have been saved!

Much was made during the election of the fact that the new member, being elected for five years, would necessitate an additional election with all the expense in the future. I had intended to ask the successful candidate whether he would not obviate this by resigning when the other members had to be elected. It is the greater pleasure to find that Mr. Victor Horsley has anticipated my suggestion, and in thanking the constituency for the honor done him announced his intention of resigning at the end of the term of his fellow-representatives.

Dr. Glover has incurred the wrath of the "Corporate and Medical Reform Committee." Instead of answering the series of questions sent to candidates and also to him, Dr. Glover wrote a letter which is a scathing criticism of the gentlemen who assumed the right to ask questions of the direct representatives. Dr. Glover has no sympathy with noisy agitators and delivers some home truths. Nevertheless, I doubt his wisdom in this case, for it may be held that every constituent has a right to heckle his member, and there is something to be said in favor of the views put forward by this last self-appointed committee. Dr. Glover is a strong man, a general practitioner of the highest grade, supported on this ground by general practitioners and consultants too. He is also an able penman, a constant contributor to *The Lancet*. He belongs to a family of able men—one of his brothers is a distinguished divine.

At the opening meeting of the Pathological Society the president (Dr. Payne) remarked in his address that some criticism had been of late offered on the name of the society, but he held that the founders had no choice in the matter and no one could expect an alteration at this date. He thought the association of the idea of morbid anatomy with the term pathology regrettable as giving an incomplete view. He defended the rule of the society, that except in special cases communications could not be received unless accompanied by a material specimen of some sort. The study of disease rests on a double foundation—anatomical and functional change—and the society belongs to the anatomical investigators. Sydenham and Locke neglected the anatomical side of pathology, but had they lived at the present time they would probably have held different views. The term morbid anatomy should not be restricted to post-mortem examinations but should include the investigation of all material change of organs and tissue by all available means. He held it to be a mistake to call everything clinical if observed during life, for even physical diagnosis is related to pathology, signs becoming significant only when connected with known changes. Dr. Payne hoped the society would continue to bring the results of pathological research into relation with practical medicine, reporting them in a manner intelligible to all interested in the subject, even those not engaged in research.

Professor Coats, of Glasgow, has been granted leave of absence to spend the winter in New Zealand, in the hope of restoring his impaired health.

A difficulty has arisen between Dr. Macewen and the manager of the Western Infirmary. I should hope Scotch intelligence and fair play will be equal to solving it.

The suicides of two practitioners have occurred during the week. Prussic acid was the agent in both cases. One gentleman seems to have been driven to insanity by anxiety about his patients. He had been in the habit of taking narcotics. The other was confronted with a threat of having some charge brought against him.

The mortality from diphtheria is again increasing here.

Dr. Bell Fletcher, F.R.C.P., died on the 21st, aged ninety-one years. For many years he was the most busy consultant of the Midlands. He retired only about a dozen years ago, shortly before which I was chatting with him. He was aged then, and I hardly expected he would reach ninety. It is twenty years since he was made consulting physician to the Birmingham Hospital, after thirty years of active service. He took great interest in the other Birmingham charities and societies, supporting them by his work and his purse. He became a fellow of the London College of Physicians as long ago as 1848.

OUR PARIS LETTER.

[From our Special Correspondent.]

VERDICT IN THE TRIAL OF DR. LAPORTE — THE BOUCICAUT HOSPITAL—THE CONTAGIOUSNESS OF LEPROSY—THE FACULTY OF MEDICINE'S NEW SCHEDULE OF STUDIES—PARIS CABS—IMMUNIZING A HORSE BY MEANS OF A TYPHIC BACILLARY CULTURE.

The trial of Dr. Laporte, which has been one of the great *causes célèbres* at Paris, and has engaged lay as well as professional attention for many weeks past, has terminated. The verdict of the tribunal was three months' imprisonment, waiving execution of the penalty. Thus the doctor, while not going actually to prison, remains all the same condemned. The circumstances were sufficient to justify an absolute acquittal. In the future, physicians "caught" in remote districts in urgency cases, and without the necessary instruments to perform craniotomy prescribed in standard works on obstetrics, may hesitate to interfere. Mother and child might thus both be sacrificed. The case has aroused the old quarrel—with which you in New York are also familiar—between lawyers and doctors. A subscription has been started in favor of Dr. Laporte by the medical profession, which is likely to realize something handsome.

Madame Boucicaut, the Parisian benefactress, who died some years ago, bequeathed to the Assistance Publique large sums to found a hospital. It was expected that the great hospital of the Rue de la Convention would be ready for inauguration three months ago. The construction and arrangements were at that time not sufficiently advanced, and a delay was demanded until October 15th. It is to be hoped that this munificent gift will be entirely available and ready for occupancy before the cold weather which is coming falls too heavily upon the sick poor.

The contagiousness of leprosy is just now being discussed by Paris physicians, who seem to be pretty

united in their opinions on the subject. Dr. Besnier, an authority of the first order on skin diseases, thinks that leprosy is not always nor everywhere equally contagious. There are also many eminent observers who have concluded that the disease is not contagious at all. This is undoubtedly true under certain conditions of locality and climate. But in a disease like leprosy we must judge of the universal field comprising different parts of the globe, and what takes place in leprous districts as a whole, and not in one place, city, or special country. It will thus be seen that the contagiousness of leprosy is a fact that it is impossible to deny. Dr. Hansen, who is one of the most expert on leprosy, is a decided partisan of contagion.

The Faculty of Medicine has issued its schedule of studies and practical work for the academic year 1897-98. The lectures and different courses begin on Monday, November 1st. As it may be interesting and even profitable to the deans of medical schools, colleges, and universities in the United States to know exactly how medicine is taught in the great École de Médecine de Paris, I give the following summary, noting in the first place that the general course of study has been lengthened from four years to five, by decree of July 31, 1895:

First year—Anatomy, histology, physiology, biological chemistry, elementary general pathology (propædeutics); obligatory practical work: biological chemistry, dissection.

Second year—Anatomy, histology, external pathology, medical and surgical clinic; obligatory practical work: hospital stage, dissection.

Third year—Internal pathology, external pathology, operative medicine, obstetrics (accouchements), pathological anatomy, natural medical history (parasitology), medical and surgical clinic; obligatory practical work: hospital stage, pathological anatomy, parasitology (animal and vegetable parasites).

Fourth year—Therapeutics, hygiene, legal medicine, pharmacology, botanical materia medica, medical and surgical clinic, special clinic, obstetrical clinic, chemistry and physics applied to hygiene and therapeutics, history of medicine and surgery; obligatory practical work: special hospital stage; elective practical work: botanical materia medica, chemical materia medica, pharmaceutical materia medica, bacteriology, etc.

Fifth year—Elective practical work: botanical materia medica, chemical materia medica, pharmaceutical materia medica, bacteriology, etc.

Several of the Paris cab companies are still sending out open carriages, although the weather is much colder and winter is approaching; in thus disregarding the public health, they are exposing their occupants to severe colds, bronchitis as well as pneumonia, and furnishing cases for the doctors.

Dr. Van de Velde reported at the last meeting of the Biological Society that at Louvain they have been for two years past immunizing a horse by means of cultures of a single variety of the bacilli of typhoid fever.

Compression of the Sciatic Nerve.—Dr. Arullani (*Gaz. d. Osp. e d. Clin.*, February 28th) has improved upon digital compression for sciatica by substituting a double-pad apparatus for the fingers. He has applied it to forty patients: two were improved, six were unimproved, and thirty-two were cured. He recommends compression of the popliteal cavity besides the point where the sciatic nerve emerges in the thigh. The general condition of the patient and the location of the pain are better criteria for the success of the measure than electric tests or the duration of the affection.

Surgical Suggestions.

The Treatment of Deep-Seated Thoracic Aneurisms.—Dr. Clarke, in the *Clinical Journal*, December 9, 1896, says that the most essential points in the treatment are rest and restriction of the amount of fluid taken. The diet should be light and easy of digestion, the amount taken at each meal being small. It is difficult to get patients to remain on the rigid Tufnell diet. The amount of fluid taken can gradually be reduced to a pint in twenty-four hours without great discomfort to the patient at rest. Rest should be absolute in the recumbent posture. This treatment should be carried out for at least three or four months, when if the patient shows decided improvement he may be allowed to sit up in bed and then gradually to move about. Dr. George Balfour recommends iodide of potassium as the most valuable medicine, although its exact mode of action is uncertain. It is administered every eight hours at first, in a dose of seven or eight grains, and gradually increased so long as there is no acceleration of the pulse, until fifteen or twenty or twenty-five grains are given at each dose. Dr. Clarke cites two cases of aneurism of the transverse aorta cured in this way.

Local Anæsthetic.—For a five-minute effect apply:

R Chloroform	10
Ether	15
Menthol	1

LI GERANT *and* PIERRE.

Indications for Hysterectomy.—Hysterectomy is advisable in the vast majority of cases of fibroid tumors of the uterus: 1. In all cases in which there are urgent symptoms from pressure, or in which there are urgent subjective symptoms referable to the uterus. 2. In all fibrocystic, œdematous, and myomatous tumors. 3. In all tumors of intraligamentous or subperitoneal growth. 4. In all large tumors which have become decidual abdominal.—PENROSE.

To prevent ankylosis after phlegmon of the hand, begin active and passive motion from the beginning of the process of repair. Joints are to be manipulated for several minutes at a time for two or three hours a day.

Open Tendon Injuries.—Dr. Carl S. Haegler (*Beitr. zur klin. Chir.*, xvi., No. 2) reports one hundred cases treated at the surgical clinic of Professor Socin. The preparation for operation is as follows: The parts are thoroughly cleansed and disinfected by sublimate solution, 1 to 5,000. An elastic bandage is applied centrifugally to the uplifted arm, and left in place until the dressing of the wound. The hand of the assistant is not so efficient as these bandages. The bloodless method is not used. Operations are performed without general anæsthesia, except in the cases of children. The bandage dulls the pain, which at most is not great. In suturing the skin or enlarging the wound cocaine is sometimes used. The search for tendon ends is sometimes difficult. Sharp hooks should not be used. When single tendons of the flexor communis digitorum are divided, Filiget recommends hyperextension of the adjoining finger as very successful in causing the tendon end to appear in the wound. When it is necessary to make an incision, an enlargment of the original wound is best. Starting from one angle of the original cross-wound, an incision is made parallel and to one side of the injured tendon; turning back this flap gives ample room to find the tendon. By this incision adhesion of the tendon sheath to the skin cicatrix is avoided as much as possible. After the ends are approximated

comes the question of suture. An ideal operation must completely approximate the divided ends, the ends must be in accurate apposition, nutrition must be disturbed to the least extent, the operation must be simple and quickly performed. A simple method nearly related to that of Schwarz has been used in the great majority of cases. Through the proximal end a thread is passed which serves as a tractor, and with the same needle the distal end is pierced. To avoid a change of position on the part of the surgeon, and on account of the unusual direction in which the needle must be passed, the distal end is grasped with a toothed forceps and twisted 180 degrees on its long axis, and after the needle is passed allowed to return to its normal position. In order to bring the edges into close apposition, one or two sutures are introduced, crossing over the first suture at right angles and piercing each end beyond it. Dry sterilized catgut as a suturing material has given the most favorable results. After suturing the wound is wiped out dry, thoroughly disinfected, and in the majority of cases the skin sutured. The wound is never drained; a gauze dressing is applied and the hand and wrist are immobilized by a zinc splint and starch bandage. The patient should be seen daily and closely watched for any sign of trouble. Phlegmonous inflammation ensued in eleven cases. Even though union be prevented by suppuration in wounds of the extensors over the hand and fingers, function may be in some measure restored by continuous fixation of the injured finger in an extended position. As a general rule, mechanical treatment should be begun in the third week in injuries of the extensors; in flexor injuries, during the fourth or fifth week. Every case must be treated on its own merits. The time of beginning must depend on the extent of the injury, the course of healing, the age and intelligence of the patient. Massage of the forearm should commence after the first dressing, viz., in from ten to fourteen days. The splint, which should reach to the elbow, is now removed and replaced by a shorter one, and the forearm is daily massaged. An elastic cord, one end of which is fastened to the wall or table while the other end is grasped by the patient, is a device which has given good results. Later a faradic current is applied. Of the one hundred cases thirty-five were of flexor injuries, and in sixteen of these, or forty-six per cent., the treatment gave a good functional result. In eleven instances function was restored from one-half up to three-fourths of the normal. In eight cases there was almost total loss of function, due mostly to phlegmonous inflammation. In some there were firm adhesions. Some of the cases could not be followed up. The prognosis differs greatly according to the situation of the injury. In the lower third of the arm there is often an extensive injury to the neighboring muscles and consequent adhesion of the tendon cicatrix. Atrophy of the muscles intensifies the bad results. Massage must be begun very early. Injuries over the wrist-joint are to be dreaded for the frequent serious complications due to the anatomical relations. Excellent results were obtained in a few of these cases. In injuries over the metacarpus the prognosis is bad. In phalangeal injuries the prognosis is not good, though function is not always destroyed. Prognosis in division of the flexor profundus over the last phalanx is absolutely bad. The prognosis in injuries of the extensors is very favorable. The search for tendon ends is not difficult, and, as the tendons do not glide in tubular sheaths like the flexors, the function is not so much affected by adhesions. Sixty-five cases were treated, and fifty, or seventy-seven per cent., yielded a perfect result. Simultaneous opening of the joint occurred in thirty-seven per cent. of the cases, but this complication did not prevent healing and restoration of function.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 13, 1897:

	Cases.	Deaths
Tuberculosis	195	89
Typhoid fever	18	9
Scarlet fever	124	11
Cerebro-spinal meningitis	6	3
Measles	181	10
Diphtheria	115	20
Laryngeal diphtheria (croup)	6	4
Chicken-pox	19	0

A Delicate Instrument.—A microtome for making sections of the entire human brain is being constructed on the pattern of the "automatic precision microtome" recently brought out. The manufacturers expect that the new instrument will make large sections of greater thinness and accuracy than it has been possible to obtain hitherto.

Hot Weather and Crime.—A curious investigation has been undertaken by the officers of the weather bureau in the United States. Col. Willis Moore originated the investigation, believing that there is a close connection between the condition of the atmosphere and the physical and moral welfare of the people. The results of these investigations are as follows: Taking in the whole country during January, February, and March, there were in even numbers 1,200 suicides reported in the United States; while in July, August, and September there were 1,600. In the same period there were 1,700 murders in the cold term, as compared with 2,500 in the three hot months. There were 50 persons hanged or lynched in the three cold months, and 113 hanged or lynched in the three hot months. The investigation is said to have been instituted with the idea of issuing in the near future warning of the approaches of crime waves.—*Sanitarian.*

Chief Nervous Affections of Alcoholism.—Alcoholic coma, delirium tremens with visual hallucinations, restlessness, fear, tremor, and failure of sleep and appetite, acute traumatic delirium occurring after wounds, *mania a potu* without tremor but with raving and violence, multiple neuritis with loss of knee-jerks and tenderness over the calves and nerve trunks, chronic insanity, showing in different cases either physical, mental, or moral degeneration especially prominently.—SHORT.

Typhoid.—Dr. Hare has recently published a statistical review of all the cases (one thousand nine hundred and two) treated during the past ten years by the Brand method in the hospital of Brisbane, Australia. The mortality has been 7.5 per cent.; for the five years preceding the introduction of the method it was 14.8 per cent.—*La Méd. Mod.*, May 29, 1897.

X-Rays Applied to the Stomach.—MM. Roux and Balthazard have applied the *x*-rays to a man after the ingestion of a certain quantity of bismuth. Experiments made successively on frogs and dogs have clearly shown the form of the stomach at the time of digestion. They have seen that the stomach of man, like that of the frog and dog, presents two distinct parts. The larger serves as the reservoir for the food ingested; the smaller, which is the prepyloric portion of the stomach, is the only part that undergoes any movement. These movements are violent and peri-

staltic, contrary to the opinions advanced by Hofmeister and Schutz; it forces little by little into the duodenum the matter that has accumulated in the stomach. *Sanitarian.*

Scurvy.—The experience of Nansen's expedition has given rise to discussion on the causation of scurvy. Torup believed that it is due to ptomains generated in badly preserved foods, and great care was taken in selecting the preserved foods on which Nansen's party lived, with complete success. A. E. Wright shows that the herbivora have no protection against acid administration in their food, and quickly die if it is given artificially. In the carnivora there is a provision for neutralizing acid by the waste ammonia of the body. In the human being this is less perfect, and if all vegetable food is cut off we should get an acid intoxication. But Nansen has shown that fresh blood and raw flesh are an antidote, and Wright says that this is easily explicable, because blood is not only alkaline, but it produces salts akin to those obtained from lemon juice. However, as the explorers were often without fresh blood and flesh much of their time, the immunity may have been after all due to the carefully preserved foods which they consumed.

Tobacco Smoking and Genius.—In his work entitled "Introduction à la Médecine de l'Esprit," M. Maurice de Fleury devotes a chapter to tobacco smoking from the point of view of men of letters. In the first place Balzac professed a fanatical aversion to tobacco in all its forms. In his books he invariably covers with contempt the characters whom he portrays as smokers. Next Victor Hugo; he likewise was no smoker. One evening at his house one of the guests was vaunting the beneficent effects of a cigarette on a creative imagination. The great poet at once rose in revolt. "Believe me," said he, "tobacco is more hurtful to you than beneficial. It changes thought into reverie." Finally, Zola says: "I have no definite opinion on the question. Personally I gave up smoking ten or twelve years ago on the advice of my medical attendant, when I believed myself to be affected with heart disease. But to suppose that tobacco exercises an influence on French literature raises a question of such magnitude that the most rigid scientific proof alone could dispose of it. I have known great writers who smoked without stint, but their intellects were not one whit less acute. If genius be neurosis, then why seek to cure it? Perfection is such a very tiresome thing that I very often regret having broken myself of the tobacco habit."—*Lancet.*

Health Reports.—The following statistics concerning yellow fever, small-pox, and cholera have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended November 13, 1897:

YELLOW FEVER, UNITED STATES.

		Cases	Deaths
Alabama, Decatur	November 1st	2	
Greensboro	November 1st	1	1
Mobile	November 6th to 12th	2	1
Montgomery	November 6th to 12th	1	1
Selma	November 10th	1	
Whistler	November 6th to 12th	1	
Louisiana, Baton Rouge	November 11th	1	
New Orleans	November 6th to 12th	84	36
Mississippi, Biloxi	November 6th to 11th	11	1
Clinton	November 12th	2	
Edwards	November 6th and 12th	6	
Pascagoula	November 6th and 12th	1	
Scranton	November 7th and 13th	4	1
Tennessee, Memphis	November 4th to 8th	1	

YELLOW FEVER—FOREIGN.

Cuba, Guantanamo	September 1st to 30th		
Matanzas	October 20th to November 3d

Winter Health Resorts.

INTELLIGENT people everywhere recognize the importance of pure air and sunshine as the essential means of acquiring a healthy constitution and maintaining it, and as indispensable for restoring it when from any cause it has become impaired. But it is only just now, as it were, that people have begun to learn the twofold effect of a bountiful supply of pure air and sunshine; that, while these agents are essential to the procurement and maintenance of human health, they are inimical to microbic life, and to none more so than to the tubercle bacillus; and conversely, that climatic or any other conditions restricting the needful supply of pure air and sunshine are promotive of microbic life, and of none more so than of the tubercle bacillus.

Nevertheless, the rigor of the winter climate in the greater part of the northern United States, where pulmonary consumption extensively prevails, is such as frequently to render the maintenance of the primary conditions essential to health impracticable for those who most need them—those who are afflicted with or predisposed to consumption.

Although the benefit to be expected from a change of climate under the circumstances indicated is by no means limited to persons so afflicted or so predisposed, the best test of the benefit to be expected from a health resort is the observed relation that it holds to consumption and its favoring conditions, as compared with the locality to be abandoned. This test is justified by the fact that consumption is less amenable to mere medical treatment than any other disease, and by the excess of the mortality caused by it over that of any other disease in districts where it prevails. Moreover, places relatively exempt from consumption are ordinarily correspondingly exempt from other diseases propagated by bacteria, and *vice versa*.

But every observant physician knows that the cure of consumption by change of climate depends upon the promptitude with which the change is made—that it should be made at the earliest possible period after the incipient symptoms have been discovered, when the constitution is otherwise sound and the physiological functions are regular. In such cases a cure is frequently effected by a judicious change of climate, and in those predisposed to consumption, before it has been developed by unfavorable conditions and exposure, resort to some place where there are a large preponderance of sunshiny days and a temperature that will admit of much outdoor exposure, where it is neither too cold nor oppressively warm, where the food is wholesome and the water pure, where commodious and well-ventilated bedrooms and healthful surroundings are obtainable, the disease is preventable.

Such resorts, approximately, it is the purpose of this paper to designate.

OCEAN AND HIGH-ALTITUDE RESORTS.

Recent knowledge of microbic life, as related to the purity of the atmosphere, justifies the inference that the benefit to consumptives derived from sea voyages or from resort to high altitudes is independent alike of the extreme density and moisture of the ocean atmosphere in the one case, and of the rarefaction and dryness of the air in the other. In both cases the air is inimical to tubercle bacilli, as it is also inimical to other bacilli—indeed, to all microbic life. And, barring the preventable conditions of a foul bilge and inadequate ventilation of staterooms and other sleeping-quarters on board ship; close bedrooms, defective house drainage, unhealthful surroundings, and dust—barring these conditions respectively, ocean atmosphere and high altitude are alike propitious and commendable to persons afflicted with or predisposed to pulmonary consumption.

Ocean air, however, it should be understood, is not the air of the seacoast, but of the open sea, sufficiently distant from the land to be free from all contamination. It is more equable and, in corresponding latitudes, excepting the tropics, warmer than over the land; and within the tropics, though warm, is never sultry, as it is at the same degree of temperature on the land, nor is the temperature so high. In the tropics, the range of the thermometer at sea is from 72° to 84° F., and rarely as high as 86° F. at midday. The mean relative humidity is about 73.5 per cent. (100 representing complete saturation). The humidity is usually a little greater in the night than during the day, but commonly is less at all times than that of the air of seacoast places.

Besides the excess of moisture, as compared with that of the land distant from the seacoast, the ocean air always contains some sea salt, although, excepting in the trade winds or in gales, in infinitesimal quantity; never in such excess even in the trade winds or gales as to be otherwise than a healthful stimulus to respiration. It also possesses properties beneficial to certain specific diseases.

The special advantages of an ocean atmosphere are:

1. Its entire freedom from the dust common to domestic conditions—particles of tissue wastes of all sorts, hair, straw, feathers, cobwebs, insects, dried sputa, etc.; from traffic dust—the wear of travel and friction; from all insoluble and irritating grit wafted from paved streets, houses, walls, dusty roads, or sandy plains. It is air, in short, that contains a maximum of the elements essential to life and health, and a minimum only or none at all of the deleterious substances always floating, in greater or lesser degree, in the lower stratum of the atmosphere over the land.

2. Complete change of scene and rest; relief from all sources of excitement and worry—newspapers, telegrams, messenger boys, letters, expectations, and all sorts of indescribable turmoil. And the passing breeze is not from just over the marsh or stagnant pond, nor is it from the malodorous tenement-house district; it bears no foul emanations and no disease germs. Every breath of it is brand new, and when exhaled it never hovers round to taint the next inspiration, but is wafted away and speedily transformed into the pure elements of the atmosphere.

Thus inhaled throughout the day, the pure soft air soothes the nerves, invigorates the functions, promotes sleepiness, and welcomes repose. Sound slumber supervenes, and with no business appointments to be met

abundant time is taken for breakfast, dinner, and supper—with an invigorated appetite and improved digestion.

The invalids to whom an ocean atmosphere is most commendable are pointed out by that which is just above stated—consumptives in the incipient stage and persons predisposed to consumption; persons of scrofulous diathesis; persons afflicted with nervous *complaints*—not organic nervous diseases, but the easily recognized conditions of overwork though often undefinable, the result of physical or mental nervous strain, anxiety, worry, irritability, debility, nervous breakdown, insomnia; and persons afflicted with chronic nephritis.

But firstly of—

Inland and Seacoast Resorts.

Winter resorts—resorts for invalids that will permit the utmost outdoor exposure—are not to be found north of or even in the vicinity of New York City. It may be remarked, however, in relation to the constant danger of nervous or physical breakdown of those who are too intensely engaged in the struggle for preeminence in city occupations, that the difference in the temperature of the atmosphere, or mere change of place, is of much less significance to them than *rest*—rest, though it may be but for a week or two, or for even a few days at a time, with such a total relinquishment of their occupations and under such conditions as will admit of recuperation.

Lakewood, N. J., about two hours from New York, situated on a sandy soil, seventy feet above sea level, in the midst of a pine-woods region, is an admirably appointed resort for rest and recuperation, with abundant hotel accommodations at moderate rates.

Atlantic City, ninety minutes from Philadelphia and four hours from New York by railroad, besides being a deservedly popular summer resort, possesses some unusual advantages as a winter resort, considering its latitude. The trend of the coast at this point is such as to bring it almost directly in the face of the westerly and northwesterly winds, which considerably modify the temperature of the ocean atmosphere. According to the records of the United States signal station at Atlantic City, as published several years ago, the average mean temperature for December, January, February, and March for a number of years was 35.8° F. The prevailing winds in winter are from the west and northwest. Several hotels are kept open during the winter, at moderate rates.

Old Point Comfort, with its delightful Hotel Chamberlain, is the favorite winter resort for those not caring for a more southern climate. The hotel is admirably equipped with every appurtenance promotive of comfort and pleasure—open-air pavilions over the water, verandas inclosed in glass, enabling invalids to enjoy the sunshine and water view without exposure; in short, everything calculated to make a sojourn here pleasant. As a place of rest for the overworked and those suffering from insomnia and worry, Old Point Comfort with all its attractions is commendable.

Virginia Beach, thirty miles from Old Point Comfort and six miles south of Cape Henry, comprehends similar conditions and advantages, with the addition of pine woods, which exercise a modifying influence on the climate. And here it may be remarked of pine forests generally that they add to the salubrity of their region. Even the great Dismal Swamp forests of Virginia and North Carolina are known to be healthful in the interior, while on its borders or in portions where the trees are felled it is, like the seacoast, commonly insalubrious. Humid air charged with miasmatic emanations is deprived of them in passing through a pine forest. At Virginia Beach the Princess Anne Hotel, with every modern convenience, is situated within a few yards of the ocean while at the rear of the hotel is the dense pine forests.

Old Point Comfort and Virginia Beach, as well as Norfolk, are accessible from New York by the Old Dominion Steamship Company's line. Fares from New York to Old Point, $8; round trip, $13. The same to Norfolk. To Virginia Beach, $8.50; round trip, $13.50. Hotel rates, $3 to $5 per day. The Old Dominion line dispatches one of its comfortable and commodious ocean-going steamers every week day for these Virginia ports, and the night at sea generally proves a delightful break in the journey.

"The Warm Springs Valley" of Virginia derives its popular name from the numerous supplies of thermal mineral waters which it affords. It is a valley of about two miles in average breadth and nearly thirty miles in length, parallel with the main Alleghany divide, between towering mountains, from the crest of which, four thousand feet above sea level, the intervening stretches of country present a marvellous panorama of mountain scenery.

The altitude of the valley (about eighteen hundred feet) and its protection by the surrounding mountains from wind storms and sudden changes, combine to produce a temperature relatively mild for the winter in this latitude, and delightful for the rest of the year. Moreover, there are at short distances apart many gaps through the mountains, extending quite to the foot of the ridge, and these present picturesque gorges, some with narrow roads, but many with creeks winding their way to Jackson River, a tributary of the James. This somewhat peculiar topographical feature insures excellent drainage of the soil and atmospheric circulation, an exceptional advantage not often found in narrow valleys hemmed in by lofty mountains, which exclude the sun's rays for a considerable portion of the day.

The Hot Springs lie at the head of one of these intersecting gorges, and Cedar Creek, which is formed by the united body of their waters, rushes down the steep declivity of the gorges, so as to clear the main valley within a few feet from their sources. Twelve or fifteen miles from Hot Springs the valley terminates abruptly by merging into that of Jackson River, but at an elevation of about two hundred feet above the river; and just here the Falling Springs Creek, descending from the Warm Springs Mountain on the east, crosses the road, and thus presents the picturesque spectacle of an unbroken fall from the top of the precipice to the valley beneath. This miniature cataract, miniature as to breadth and volume of water, is half as high again as that of Niagara, and was considered by Mr. Jefferson worthy of description in his "Notes of Virginia."

The waters of these springs—Hot and Warm Springs (Bath County)—have been analyzed by several distinguished chemists, with nearly identical results. They are classifiable chiefly as alkaline-calcic. The Boiler Spring, in particular, has been not inaptly compared with the springs at Aix-les-Bains, in France, though it has a slightly higher temperature—Boiler Spring, temperature, 108° F.; Aix-les-Bains, 103° F.

	Grains per gallon.
Magnesium sulphate	8.476
Magnesium carbonate	3.018
Calcium sulphate	1.895
Calcium carbonate	23.076
Sodium sulphate	3.084
Potassium chloride	.530
Silica	1.946
Total	42.014

Carbonic acid is given off freely, but is not here measured.

The hotel accommodations and the facilities for

using the waters are abundant and excellent, and at moderate rates.

A branch railway, twenty-five miles in length, has recently been built from Covington, Va., to the Hot Springs, and direct connection is made with through trains east and west bound on the main line of the Chesapeake and Ohio. The Warm Springs Valley can now be reached by rail in fourteen hours from New York, twelve hours from Philadelphia, nine hours from Baltimore, eight hours from Washington and Richmond, ten hours from Norfolk, and twelve hours from Cincinnati. Arrangements can be made when desired to run through cars from any of the cities named, or from points beyond, direct to the Hot Springs.

Especial attention is invited to the fact that the Hot and Warm Springs Valley lies midway between New York and Cincinnati, and is reached in one night's ride from either point.

For many persons a most restful change from the monotony of daily life may be obtained by a trip on one of the many stanch and beautiful steamships of the Atlantic coastwise routes, or the trip may be extended to such nearby places as Bermuda, the Bahama Islands, Jamaica, or still farther to the Windward Islands, the most eastwardly of the West India group.

A trip to Cuba just now naturally does not present much attraction. We have already referred to the steamers of the Old Dominion Steamship Line to Norfolk. In addition to these there are steamers running regularly every week and oftener to Charleston, to Savannah, and to Jacksonville, Fla.

The Bermudas are within forty-eight hours of New York, in the same latitude, 32° 45′ N., as Charleston, S. C., and six hundred miles east of that city. There are three hundred and sixty-five islands in the group, counting some very small islets, all formed by the irregular crests of a bank of coral and separated by narrow channels. The most of them are covered with semi-tropical vegetation, and some of them are remarkably beautiful and picturesque. Only about twenty of them are occupied as dwelling-places, but all are delightful points for boating and fishing. Bermuda, the principal member of the group, is sixteen miles long by one and one-half miles wide. Hamilton, the chief town, has about eight thousand inhabitants, and several excellent hotels, at from $2 to $4 a day, or $12 to $21 a week; and a number of good boarding-houses, at $10 to $12 a week. St. George, on an island of the same name and next in importance to Bermuda, approximates Hamilton in the excellence of its hotels and boarding-houses, and at similar rates. St. David's, Somerset, and Ireland are also important islands, and are alike enjoyable for the beauty of the scenery and the excellence of the roads. There are no mountains to climb and no rivers to cross in Bermuda—the greatest altitude being but about two hundred feet above sea level; but there are many rocky towers and precipitous roadbanks and as many deep cuttings needful to reach the beautifully level roadbed—hard and generally without dust. There is no end to these roads (altogether they are said to be nearly two hundred miles in length), at one instant winding through artificial gorges whose banks are overhung by a profusion of trailing plants, maiden-hair ferns, and fragrant flowers, and at the next, with glimpses of the sea and the islets scattered round flashing into view, revealing new pictures in the ever-changing beauty of the scene.

These islands are reached by the steamers of the Quebec Steamship Line.

Nassau, the capital of the Bahamas—the most northern of the West India Islands—situated on an elevation about seventy-five feet above sea level, in latitude 25° 5′ N., has been long and justly regarded as a congenial winter resort for consumptives, for those affected with nervous disorders and breakdowns, and for invalids with Bright's disease. The streets are of the natural limestone rock, and there are several interesting drives about the island. There are a tropical profusion of flowers and trees, a public library, museums, and several churches. The Royal Victoria Hotel is open during the winter and has an excellent reputation; $2.50 to $4 a day. Harbor Island, a few miles distant from Nassau, is also a place of good repute, but the writer has no knowledge of its hotel accommodations. The mean winter temperature of Nassau is about 70° F.; the range is from 64° to 82° F. It is accessible by means of the Ward Line, 113 Wall Street, New York. As the fleet of this line is large, it makes weekly sailings and excursions to Nassau for $50, to Mexico for $100, to Cuba for $60. Another excursion of twenty-two days to Nassau and to the south side of Cuba is offered by this company, the entire cost being $100, including board while in port.

Jamaica is the largest of the British West India Islands, comprehending an area of forty-four hundred and forty-two square miles, and a population of about six hundred thousand. The general appearance of the island is exceedingly beautiful, but not all of it is healthful. The Blue Mountains extend through its entire length; indeed, the whole island is wellnigh comprehended in them, for, on all sides from the water's edge up, the ascent is in ridges and hills of continuously increasing altitudes, intersected by vales and streams with more or less abrupt precipices and overhanging cliffs—all covered with richest tropical groves and undergrowth, exhibiting the most romantic scenery, and culminating at a height of seventy-three hundred feet above sea level, yet never capped with snow.

Between the mountain ranges and ridges there are extensive plains and spacious savannas, whose water-logged soil, like that along a considerable portion of the extensive coast line of over five hundred miles, is more or less productive of malarial fevers. But these localities are easily avoided, as they should be, by resort to some of the many healthful localities on the mountain slope, at an altitude of twenty-five hundred feet and upward, entirely exempt from malarial diseases. At this altitude (twenty-five hundred feet) the winter range of temperature is from 55° to 65° F. It is about one degree lower for every three hundred and forty-five feet increase of altitude. Mineral springs have been discovered in several localities in the island; with but one exception there is no published analysis of the waters, and this is of the "sulphurous sodic-calcic thermal springs," near the village of Bath, about twenty miles from Kingston, reached by an excellent road through beautiful scenery. The waters are said to resemble those of Bath in England, and to be of much value in the treatment of rheumatism and gout. The published analysis gives the following chemical constituents in one gallon of the water:

Chloride of sodium	13.84
Chloride of potassium	0.32
Sulphate of calcium	5.01
Sulphate of sodium	6.37
Carbonate of sodium	1.69
Silica	2.72
Oxide of sodium combined with silica	1.00
Organic matter	0.25

The springs are situated in a deep ravine about one and one-half miles from the village, accessible by a good road, where bathhouses have been constructed for those who wish to use the waters. The island is intersected by splendid macadamized roads, besides railways, and, considering the large number of accessible and well-appointed localities, with good hotels

at $3 to $4 a day, at various altitudes and with healthful surroundings, it is, taken altogether, a winter resort of exceptional excellence. On account of the rainfall, however, which is great at other seasons, the preferable period for enjoying the climate of Jamaica is precisely that which is the most convenient for rounding out this winter voyage—January to March, the relatively dry season.

This island is reached by steamers of the Quebec Steamship Company, and also by the Atlas Line from New York.

For those who have the time and inclination, a trip by the steamers of the Quebec Steamship Company to the Windward Islands is extremely delightful. The first stop of this line is at Santa Cruz. Next comes the Island of St. Thomas. These two islands are under the Danish government. "English spoken."

Then comes St. Kitts, an English island of great beauty and fertility, with good hotel accommodations. Sixty miles east the steamer touches Antigua, also under the English government. Then come Guadalupe, Dominica, and Martinique. Santa Lucia comes next, and then Barbadoes, the most eastward of the Windward Islands, in latitude 13° 10′ N., and longitude 59° 32′ W. Steamers of this line often touch at other smaller islands. The rates of passage include living on the steamer from the time one leaves New York until he returns.

Still another but shorter voyage is by the vessels of the Red "D" Line to Curaçoa and Caracas, both interesting and healthful winter resorts. Curaçoa is a Dutch island, in latitude 12° 20′ N., about fifty miles from the coast of Venezuela, with a climate very similar to that of Barbadoes. Caracas, the capital of Venezuela, is in latitude 10° 30′ N. The city is admirably laid out, radiating from a beautiful park in the centre of the town and following the cardinal points of the compass. There are many fine buildings and magnificent suburbs, intersected by good roads.

The winter climate is agreeably cool and equable. The thermometer averages about 65° F. during the night, and in the early morning ranges from 50° to 55° F.; it rarely rises to 75° F. at midday. Few climates present such favorable conditions in altitude and temperature.

There are several excellent hotels, at from $2.50 to $4 a day, where English-speaking servants are employed. Carriage hire is regulated by tariff—thirty cents for each person to any part of the city. Street-car routes from the railway stations pass all of the hotels.

Rates of passage: New York to La Guayra, $80; to Curaçoa, $70; round trip, $144.

The Carolinas.

The middle section of North Carolina ranges from six hundred to fifteen hundred feet above sea level. It is, for the most part, covered with pitch pine, and is remarkably healthful. The mean winter temperature is from 40° to 45° F., and the relative humidity 69 per cent.

Southern Pines, seventy miles beyond Raleigh, on the Seaboard Air Line, from Norfolk, is situated at an elevation of about six hundred feet above sea level, in the midst of the pine-wood region. The average winter temperature is 44° F., and the atmosphere relatively dry. It is a new resort and yet in process of improvement. The Piney Woods Inn is the principal place at which to stop.

Pinehurst, six miles west of Southern Pines (connecting by electric cars), possesses the same advantages of local and climatic conditions, with more advanced improvement round about, and hotel accommodations about the same. There are excellent roads, reasonable carriage rates, and interesting forest drives all about both these places.

Asheville, a charmingly situated city, twenty-two hundred and fifty feet above sea level, enjoys an admirably pure atmosphere, though it is rather cold for very sensitive invalids. Mean winter temperature, 37.8° F.; relative humidity, 69.3 per cent. It possesses all the advantages of the most highly favored winter resorts of southern Europe, besides the additional advantage of freedom from the sudden changes of temperature common to those resorts. Hotels are commodious and excellent, at from $3 to $5 a day. The drives and scenery are superb. Asheville is reached by six routes of travel, and each of them has features interesting to tourists.

First, *via* the western North Carolina division of the Richmond and Danville Railroad, seventy-nine miles from Salisbury, *Morganton* (Hunt House) is a popular resort, eleven hundred feet above sea level, with charming scenery. Twenty-five miles farther on is *Linville Gorge*, where the Linville River bursts through the Linville Mountains. The gorge is fifteen miles in length, and the heights which overshadow it are not less than two thousand feet. The river plunges over a precipice one hundred feet high and one hundred and fifty feet broad, and then rushes forward over a bed of rock. Cliffs worn by the ceaseless action of the water into the most fantastic shapes hang over it, detached masses strew the channel, and the tumult of its fretted waters ceases only when pauses now and then occur in crystal pools of placid gentleness. The route continues exceedingly picturesque until it pierces the Blue Ridge by the Swannanoa Tunnel, eighteen hundred feet long and twenty-seven hundred feet above sea level, and then gradually descends into the elevated basin in which Asheville lies, along the bank of the Swannanoa, one of the loveliest of North Carolina rivers.

Second: From Spartanburg, S. C., seventy miles by the Asheville and Spartanburg branch of the Richmond and Danville Railroad.

Third: From Charlotte, N. C., by railway to Statesville on the Western North Carolina Railway; or to Shelby, on the Shelby division of the South Carolina Railway, and thence to Lincolnton and Hickory, on the Western North Carolina Railroad. This route is through the famous *Hickory Nut Gap*, the scenery of which has been declared by some European travellers to be equal in beauty and grandeur to that of any pass in the Alps. The entire length of the Gap is about nine miles, the last five being watered by the Rocky Broad River. The gateway of the gorge on the eastern side is about one-half mile wide, and from this point the road winds upward along a narrow pass, hemmed in on all sides by stately heights. From the summit of the Gap there is a magnificent view in all directions.

Fourth—for those who would prefer to journey with less speed than by the railroad, for the sake of the greater enjoyment of the scenery: By stage from Greenville, S. C., *via* Saluda Gap, Flat Rock, and Hendersonville, to Asheville, sixty miles. *Flat Rock*, once the most frequented of Carolina resorts, has been somewhat shorn of its glories during recent years, but the lovely valley of its site still remains and yet contains some noble mansions, surrounded by gardens filled with the rarest and most beautiful shrubbery and flowers.

Fifth, also by stage from Greenville, *via* Irne's Gap and Cæsar's Head to Asheville, about seventy-five miles. *Cæsar's Head* is a bold and beautiful headland, and will well repay a visit in passing. And just beyond is *Cashier's Valley*, famous for its salubrious climate. It is more of a tableland than a valley, lying on the side of the Blue Ridge, about thirty-five hundred feet above sea level, and hemmed in on all sides by higher peaks, the highest of which is Chimney Top. On the southwestern edge of the valley is *White Side Mountain*, one of the most striking peaks in North

Carolina, rising to the height of more than five thousand feet above sea level, its southern face being an immense precipice of white rock two miles long, and so curved as to form part of the arc of a circle, with many cave-like recesses with wildly picturesque escarpments around. The largest of these recesses is known as the *Devil's Supreme Court House;* and, according to Cherokee tradition, the prince of the powers of darkness will on the day of doom erect his throne here and try all the spirits who fall under his jurisdiction. The approach to it is by a long, narrow, and dangerous ledge, upon which only the most coolheaded should venture to tread. The ascent to the summit of the mountain can be made partly on horseback. The view from the summit is of surpassing grandeur. "To the northeast, as far as the eye can reach, rise a multitude of sharply defined blue and purple peaks, the valleys between them, vast and filled with frightful ravines, seeming the merest gullies on the earth's surface. Farther off than this line of peaks rise the dim outlines of the Balsam and Smoky ranges. In the distant southwest, looking across into Georgia, we can descry Mount Yonah, lonely and superb, with a cloud reef about its brow. Sixty miles away, in South Carolina, a flash of sunlight reveals the roofs of the German settlement of Walhalla; and on the southeast, beyond the precipices and ragged projections, towers Chimney Top Mountain, while the Hog Back bends its ugly form against the sky and Cold Mountain rises on the left. Turning to the north we behold Yellow Mountain, with its square sides, and Short Off. Beyond and beyond, peaks and peaks, and ravines and ravines! It is like looking down on the world from a balloon."

Sixth: From the northwest or southwest, by the East Tennessee, Virginia, and Georgia Railway to Morristown, Tenn.; thence by its North Carolina division to Wolf Creek; thence by the Paint Rock branch of the Western North Carolina division of the Richmond and Danville Railroad, which traverses the valley of the French Broad to Asheville amid magnificent scenery.

The Warm and Hot Springs of North Carolina have been long known as among the most noted mineral waters of the Southern States. They are situated in Buncombe County on the western bank of the French Broad River, about forty miles from Asheville, and are accessible by railway.

The waters vary in temperature from 94° to 104° F. An analysis of three quarts of the water by Prof. E. D. Smith (*Silliman's Journal*, vol. viii.) gives the following constituents:

[illegible]	[illegible]	[illegible]
Sulphate of magnesium	"	6
Sulphate of calcium	"	14.5
Insoluble residue	"	2.5
Loss	"	1
[illegible]	[illegible]	[illegible]

Equal to 4.66 grains of solids in a pint.

The writer is unable to find any later analysis, but they are advertised to contain "carbon dioxide, free hydrogen sulphide, carbonic acid, sulphuric acid, in combination with calcium and a trace of magnesia." The waters are chiefly used in the form of baths (though sometimes they are drunk), for which there are excellent facilities. They are of creditable repute in the treatment of rheumatism, rheumatic gout, liver and kidney complaints, and cutaneous diseases. The locality is eminently healthful and the scenery beautiful.

Summerville, S. C., twenty-two miles from Charleston on the South Carolina Railroad, has long been a favorite winter resort for those who would escape the damp and chilly winds that sweep down the coast. It is situated on a ridge extending across the peninsula between the Cooper and Astley rivers and covered with pine woods. The air is soft and balmy, with a winter temperature of about 60° F., seldom rising to 70° and rarely falling below 55°.

The Pine Forest Inn is a commodious and well-furnished hotel, with large and well-ventilated bed, bath, and toilet rooms on every floor. Its rates are from $3 to $5 a day, $17.50 to $30 a week. It has excellent stables, with or without the services of experienced drivers. There are several good boarding-houses with prices ranging from $7 to $10 a week. The roads are good, and there are many places of historical interest in the vicinity.

Aiken is of extensive repute for its healthfulness, and few places are more favorably known. It is an expanded village of about three thousand inhabitants, situated on a tableland with an excellent watershed, between the Savannah and Edisto rivers (but at a considerable distance from either), at an elevation of five hundred and sixty-five feet above sea level. The soil is sandy and much of the country round about is covered with lofty pine trees. It is to this thrifty growth and the well-drained sandy soil that the healthfulness of the region is attributable.

The latitude of Aiken is 33° 32′ N.: longitude, 81° 34′ W. Mean winter temperature, 50° F.; range, twelve degrees. Mean relative humidity, 60.65. Rainfall, 7.16 inches.

The streets are wide and well shaded, the roads good, and the drives round about interesting. There are stables well stocked for both saddle and carriage riding, and it has relatively few days when outdoor exercise is not enjoyable.

Of the hotels, the *Highland Park Hotel* is one of the most elaborate and best equipped in the country. The grounds embrace, besides fifty acres of green lawn immediately surrounding the house, thickly interspersed with shade trees and ornamental shrubbery, a pine-woods park of three hundred and fifty acres, beautifully laid out in walks and drives, with here and there a rustic seat, and in the centre of the park a glass-inclosed pavilion.

There are several other good hotels with prices from $2.50 to $5 a day, and many excellent boarding-houses at from $10 to $15 a week. There are five churches for whites, and four for colored people. A polo club and other attractions contribute to social enjyment.

Aiken is accessible: From New York, Philadelphia, and Washington, *via* the Atlantic Coast Line, direct to Aiken, leaving New York at 9:25 A.M., arriving at Aiken at 7:28 next morning, with through sleeper. Also *via* the Clyde Line of steamers to Charleston, and thence by the South Carolina and Georgia Railway.

From Chicago, the West, and Northwest *via* the various routes to Atlanta, Ga.; thence by the Georgia Railroad, connecting at Augusta with the South Carolina and Georgia Railway.

From Thomasville or Florida to Savannah, thence by the Georgia Railroad through Augusta, or the Atlantic Coast Line through Charleston. Or *via* Denmark, by the Florida Central and Peninsular, and thence by the South Carolina and Georgia Railway to Aiken.

The Southern Railway, the "New Short Line" from the North, East, and West has a direct passenger route to healthful Aiken, and runs Pullman vestibule trains and superb hotel dining-cars. A train leaves New York at 12:30 noon, arriving at Aiken at 10:55 A.M.; also at 4:25 P.M., arriving at 5 P.M.

Camden is an attractive and healthful place, situated in a salubrious region in the central part of the State, known as the "Sand Hills," about four hundred feet above sea level. The climatic and local conditions are strikingly similar to those of Aiken. There are good hotel accommodations. Camden can be reached

from New York by way of the Atlantic Coast Line to Charleston, and thence in five hours by the Charleston, Cincinnati, and Chicago Railroad.

Columbia, the capital of South Carolina, a city of about fifteen thousand inhabitants, is situated at an altitude of three hundred feet above sea level on the bluffs of the Congaree River, a few miles below the beautiful falls of that river, on a sandy soil, with extensive pine forests in the vicinity. There are many handsome residences and imposing public buildings, with beautifully shaded streets and charming flower gardens. In the suburbs are handsome parks and pleasure grounds, good roads, and pleasant drives round about. The winter climate is similar to that of Summerville.

There are several good hotels, at from $2.50 to $3 a day. It is reached by the Richmond and Danville Railroad direct, or *via* steamer to Charleston, thence by the South Carolina Railroad.

Spartanburg, in the northern part of the State, two hundred and twenty-three miles from Charleston, and ninety-three from Columbia by the Greenville and Columbia and Spartanburg and Union railways, is pleasantly situated in the mineral region, famous for its gold and iron mines and *mineral waters*, and yet more famous for the memorable battle ground of the Cowpens, in the vicinity, where on January 17, 1781, occurred the defeat of the British under Tarleton.

Glenns Springs here are strongly impregnated with sulphur and contain sulphate of magnesium, with sulphate, bicarbonate, and chloride of calcium. The waters are considered efficacious in certain forms of rheumatism, scrofula, and dyspeptic complaints. *Limestone Spring* is chalybeate, and possesses valuable tonic properties.

Spartanburg is situated on high ground with healthful surroundings. The temperature here is somewhat lower than at Aiken, and the springs are a summer resort for Charlestonians to some extent; but they are also good as a winter resort, particularly for Northern people who would avail themselves of the benefit of such waters under congenial climatic conditions. There are good hotel and boarding-house accommodations.

Chick's Springs, Greenville, ninety-three miles nearer Charleston, at the foot of Saluda Mountain, on the Ennoree River, are also favorably situated as regards climate. There are two springs: the waters of one are slightly sulphurous and of excellent repute in the treatment of hepatic affections; the other is mildly chalybeate and commendable to anæmics. The region is eminently salubrious, and at Greenville there are excellent accommodations for visitors.

Georgia.

The Pine Forests of Georgia are a continuation from the Carolinas, but of even greater extent. They reach from one end of the State to the other, along the eastern and middle section, and save for a district extending seventy miles or so inland from the coast are everywhere healthful.

Savannah, however, though only eighteen miles from the mouth of the river of the same name and but forty feet above the level of the sea, is a delightful winter resort. Its beautiful parks, magnificent live oaks, evergreen shrubbery, and beautiful flower gardens add enchantment to the soft, mild climate. It is in latitude 32° 5′ N.; longitude, 81° 5′ W. The mean winter temperature, 54.5° F., is but slightly variable, and, with prevailing westwardly winds and little rain, makes congenial weather. The attractions round about, good roads and every accommodation desirable for their use, are well calculated to promote health. The scope of this paper will not permit much detail, even of the most interesting objects, but one can hardly forbear particularizing the rare spectacle of the great live oaks which shade Bonaventure Cemetery, to be seen nowhere else in such magnificence. More than a hundred years ago these grounds were laid out in broad avenues and planted with native live oaks scattered through the extensive lawns that surrounded the mansion of the Tatnalls, and these trees have been growing ever since. They stand in great columns on either side of the walks, while their far-reaching branches interlace overhead, like the fretted roof of some vast cathedral. The deep shade of their ever-green foliage shutting out the sky above, and the long gray-moss drapery depending from the leafy canopy, at times silent, at times gently swaying in the breeze, give to the scene a weird and strangely sombre aspect, at once picturesque and solemn. A more beautiful or more significant and appropriate monument to the dead than the shades of these forest aisles cannot be imagined. There are many beautiful and several historical monuments of interest.

Hotels are abundant and excellent, at from $2.50 to $4 a day.

Steamers run from Boston, Philadelphia, and Baltimore to Savannah. By railway it may be reached by the Atlantic Coast Line *via* Richmond, Wilmington, and Charleston; or by the Richmond and Danville Railroad to Columbus, and thence by the South Bound Railroad; from Cincinnati, St. Louis, and Memphis, by the Louisville and Nashville Railroad, and branches *via* Chattanooga and Atlanta, and by the Central Railroad of Georgia; from New Orleans by the Louisville and Nashville Railroad and the Savannah, Florida, and Western Railroad.

Augusta, a handsomely laid out and beautiful city, is situated at the head of steamboat navigation on the Savannah River, one hundred and thirty miles from its mouth, at an elevation of one hundred and eighty-five feet above sea level. The sanitary administration of the city is of exceptional excellence. The climate is similar to that of Aiken, from which it is only seventeen miles distant. There are good roads and beautiful scenery round about, and, taken altogether, as a winter resort for persons predisposed to or affected by consumption, Augusta possesses many advantages. The hotel accommodations are ample and excellent, and rates are moderate.

Augusta is accessible by way of the Savannah River and by the Central Railroad of Georgia; from the North by the Piedmont Air Line *via* Washington, Danville, and Charlotte, or by the Atlantic Coast Line *via* Washington, Richmond, Wilmington, and Columbia.

Thomasville, a town of about six thousand inhabitants, is situated on the Savannah, Florida, and Western, and the Altantic and Gulf railroads, two hundred miles southwest of Savannah, twelve miles from the Florida State line, in the midst of the long-leaf pine region, at an altitude of three hundred and thirty feet above sea level. The average winter temperature is 55° F. The streets are broad and well shaded, and the walks pleasant. It is a churchly community—Episcopal, Methodist, Baptist, Presbyterian, Roman Catholic, and Jewish denominations being represented. The excellent drives through the pine woods and the scenery round about, with the prevailing sunshiny weather, are important among the advantages of this deservedly noted resort.

There are three good hotels and a number of excellent boarding-houses at moderate rates.

Florida.

Those who would measure climate at the level of the sea by the meridian only will wholly fail to form a correct conclusion with regard to Florida. Northern Mexico, the peninsula of California, the Desert of Sahara, Central Arabia, Northern Hindostan, Northern

Burmah, Southern China, and numerous other regions less known and some of them insular-like, and in the same latitude as Florida, have climates more or less similar to each other, but all of them are strikingly different from that of Florida; and for the reason doubtless that none of those localities is bounded by an immense body of warm water on one side and a swiftly flowing ocean current on the other, and the peninsula between covered for the most part by a pine forest—a combination of influences conducive to healthfulness not found to anything like the same extent in any other region of the same latitude lying near the level of the sea, Florida's greatest altitude being nowhere more than three hundred feet.

Florida lies between the parallels of 24° 30′ and 31° north latitude, and 87° 30′ west longitude. The mean winter temperature is about 60° F.; mean relative humidity, 72.7. Average number of rainy days during the five months, November to March inclusive, for a series of years at Jacksonville (Signal Service records), 37.4. The dryest month is November, immediately following the wettest part of the rainy season. The winter weather altogether throughout the State is generally such as to allow outdoor exposure some portion of every day, and the preponderance of sunshiny days, with an almost constant gentle breeze from over the sea and through the pines, permits the fullest open-air enjoyment; and so generally do these conditions prevail the tourist can hardly go amiss with regard to his outdoor programme. But here, as indeed everywhere else—however good the promises and beautiful the premises—the tourist *should always* be alert as to the conditions of his sleeping-quarters and their immediate surroundings.

Jacksonville is the gateway at which the steamships, steamboats, and railways enter, the latter radiating thence throughout the State. It is a beautiful city of thirty thousand inhabitants, wide and well-shaded streets, and handsome parks. There are a half-dozen or more excellent hotels. The *St. James*, facing St. James Park, the most elevated grounds of the city, has accommodations for five hundred guests, and is provided with all the comforts and conveniences which characterize a hotel of the first class. The rates are $4 a day, with special weekly and family rates. The *Everett* and the *Windsor* hotels are also beautifully situated, and of like proportions with the St. James and at the same rates. The new Duval, the Carlton, St. John's House, the Grand View, Tremont House, the Travellers', and Hotel Placide offer good accommodations at from $2 to $3 a day. There are also many good boarding-houses at from $8 to $14 a week. From New York, Jacksonville is most comfortably reached by the Clyde Steamship Company's ships, 5 Bowling Green, the passage costing $25; excursion, $43.30. By rail the Atlantic Coast Line, *via* Washington, Charleston, and Savannah, runs vestibuled trains with buffet and sleeping cars through in twenty-eight hours, without change, the fare being $29.15.

St. Augustine, the oldest European settlement in the United States, is situated on the Atlantic coast on a narrow sand beach between Matanzas River on the east and the St. Bastian on the south and west, about forty miles south of the mouth of the St. John's River. The harbor of St. Augustine is protected by Anastasia Island, which lies between it and the ocean. The beach for miles around is covered with a tangled growth of palmetto and semitropical shrubs. The streets of the town are narrow, and seem to have shaped their course by crooked paths that wound their way through the tangled vegetation three centuries ago, when the town was founding, such paths being more easily followed. The streets are paved with shell, and many of the old houses are constructed of shell stone (coquina), quarried on Anastasia Island. The whole aspect of the town is *sui generis*. Like Topsy, it "just growed," and it has continued to grow in conformity with its planless beginning, more than half a century before the landing of the Pilgrims at Plymouth; but though founded on the sand it still endures.

The prevailing "style" of architecture is quaint and ancient; the verandas jut out from either side and almost touch across the streets. It is a surviving remnant of old Spain, and the objects to be seen round about are, many of them, Spanish in character and deeply interesting. Many important recent improvements have been made, however, and the current life here, which used to be described as indolent and lazy, is accumulating force, and thrift is following.

The winter climate is remarkably equable and agreeable, the mean temperature being about 58.8° F.

The *Ponce de Leon Hotel* is a building of magnificent proportions, replete with all modern conveniences and adorned with beautiful gardens of flowers and evergreens. It has accommodations for seven hundred guests at from $5.00 a day and upward. The *Cordova*, across the street, is run as an annex for the overflow of the *Ponce de Leon*. The *Alcazar*, *San Marco*, *Magnolia*, and *St. George* are comfortable hotels, with modern appointments, at from $2.50 to $4 a day, with special weekly rates.

There are at least a dozen other houses where guests are well taken care of at from $1.50 to $2.50 a day, and weekly at from $8 to $15.

Ormond, on the Halifax River, situated fifty miles down the coast from St. Augustine, on the line of the Florida East Coast Railway, and eighteen miles north of Mosquito Inlet, occupies both banks of the river, and fronts one of the finest sections of beach on the Atlantic coast. *Hotel Ormond*, on the bank of the river, is beautifully situated, and equipped with all modern conveniences. Here can be obtained, at reasonable prices, launches and row boats, fishing and hunting outfits—everything promotive of the health and pleasure of the guests. Hotel rates are from $4.50 to $5 a day; $23 to $28 a week. *Hotel Coquina* is also beautifully situated, upon a bluff overlooking the ocean, from which it is distant about three hundred feet. Among other features it has a glass-inclosed apartment which affords the famous seaside sun baths that are so highly recommended by some physicians; and also at all times an attractive view of ocean and beach. Surf bathing begins here about the 1st of February, and for this it surpasses any other place on the coast. A horse-car line from the railroad station to Hotel Coquina on the ocean shore passes near all hotels and boarding-houses. Rates are $3 a day, with special weekly rates. The Bosarvé, The Sunnyside, and The Granada furnish accommodations at from $7 to $15 a week. From Hotel Ormond dock launches ply their way up the river a distance of five miles, to the mouth of the Tomoko, in view of beautiful rolling lands devoted to the cultivation of oranges and early vegetables. As one ascends the river, the scenery increases in beauty, amid the rare double-headed palmettoes and pine forests. The route is very circuitous, and occasionally alligators may be seen. The climate is enjoyable.

From Jacksonville all points in South Florida are accessible. For **St. John's River** steamers leave daily except Saturdays, and for **Sanford,** one hundred and ninety-three miles south, stopping at intermediate landings. The banks of the St. John's are lined with luxuriant tropical vegetation, handsome shade trees, orange groves, and many picturesque villas and villages.

Mandarin, a small village on the east bank of St. John's, is one of the oldest settlements in the State.

Near the landing, almost hidden among live oaks and orange trees, stands the whilom home of the celebrated authoress of "Uncle Tom's Cabin;" and directly across the river from this place shines the white fence of Orange Park. Hibernia, New Switzerland, and Remington Park are passed, and the next landing-place is **Magnolia,** a popular resort. The *Magnolia Springs Hotel* is replete with all the modern improvements. The rates are from $3 to $5 a day; special weekly and family rates. Two miles beyond, and thirty miles from Jacksonville, is **Green Cove Springs,** which furnish sulphuretted water with a temperature of 78° F., gushing forth at the rate of three thousand gallons per minute. This spring has been recently improved, fitted up with plunge and swimming baths, and other improvements are in process; among which will be pools inclosed with glass, and all kinds of bathing-facilities. The Clarendon Hotel, which fronts the Spring Park, has accommodations for two hundred guests, and is said to be first-class in all its appointments. There are hot sulphur baths of the spring water in the hotel. Here also are the Hotel St. Elmo, the Oakland, St. Clair, and Green Cove Springs hotels, with accommodations at from $2.50 to $3 a day, and special rates by the week. Eighteen miles farther on is **Palatka,** a town of five thousand inhabitants, seventy-five miles from Jacksonville, occupying a fine, high plateau, with a wide-reaching view up and down the river. It has long been among the most favorite winter resorts in the State, and is well provided with good hotels at from $2 to $4 a day. Excellent boarding-houses are numerous at reasonable rates, and there is a great variety of social amusements. Palatka is the starting-point for the trip up the **Ocklawaha River,** the most tropical stream in North America. The journey is made in new and very comfortable boats for enjoying the scenery. Here, too, there is railway connection with Gainesville and Ocala *via* the Florida Southern Railroad for the Indian River. Moreover, Palatka is the usual and best point of departure for the hunting and fishing grounds of the upper St. John's and the Indian River region, and those who are not provided with hunting and fishing equipments can obtain them here.

The upper St. John's from Palatka southward increases in picturesque scenery with each succeeding hour. Instead of being a broad estuary, the river now becomes narrow and tortuous, and at night, when illuminated by the powerful searchlight of the steamer, to the traveller's first view it is a picture from fairyland. Yet, narrow as it is, every few miles it expands into lakes, some of which are large bodies of shallow water teeming with ducks and other wild fowl. **Lake George,** four miles wide and eighteen miles long, is the most beautiful sheet of water in the State, considered by many tourists equal in picturesqueness to its namesake in the State of New York. It is dotted with many lovely islands, like its namesake, but these, instead of being covered with groves of timber trees and bush, are for the most part the sites of orange groves. All along, the shores and clumps of tropical bush are alive with the sweet songs of Southern birds; and here and there, in striking contrast with anything that is ever seen along the lake shores of the North, cranes and flamingoes are seen stalking the water's edge, picking choice morsels from the ripple; while off shore great boat-like pelicans are cruising about and loading their pouches with delicate fish for the little ones at home. The next point of interest is Beresford, the landing-place for the flourishing district about Deland, Lake Helen, Orange City, etc. A few miles farther up the narrow and lazy stream brings the steamer to Lake Monroe and the conclusion of the voyage—the head of steamboat navigation—at Sanford and Enterprise.

Sanford is the metropolis of South Florida. It is the terminus of seven railroads, with a daily mail service north, south, east, and west. Its late rapid growth has exceeded all expectations and greatly inspired energy in public improvements. The sanitary condition is reported to be the best in the State. It has excellent water works, a good fire department, and other public works, fine churches, and social clubs. There are many fine orange groves in the vicinity and pleasant scenery abounds. Hunting and fishing are fruitful, and accommodations for tourists unlimited. *The Sanford House* has long been famous, and there are, besides, San Leon Hotel, Sirvine Hotel, and other good houses, at from $2 to $4 a day and reduced rates by the week, and many good boarding-houses at lower rates.

Enterprise is on the opposite side of the lake from Sanford. Brock House here is famous among tourists who have been privileged to enjoy it. It is beautifully situated on the north shore of Lake Monroe, and is provided with all modern improvements, gas, electric bells, baths, open fires, telegraph office, and is, in short, one of the most homelike and comfortable hotels in the south. Rates, $3.50 to $4 a day; weekly, $17.50 and upward; special rates to families.

The Indian River section is yearly becoming more and more attractive. The "river" itself is a long lagoon or arm of the sea, beginning near the lower end of Hillsborough Lagoon and extending along the east side of the peninsula for nearly one hundred and fifty miles. It is separated from the Atlantic by a narrow strip of land, through which it communicates with the open water by the Indian River Inlet and by Jupiter Inlet; and for more than thirty miles of its northern course it flows parallel with the St. John's River, at an average distance of about ten miles.

The favorite route to Indian River is by the Clyde St. John's River Line *via* Sanford or Enterprise to Titusville, thirty-seven miles. It is also accessible by the Jacksonville, St. Augustine, and Indian River Railroad, which runs one hundred and fifty-eight miles to Titusville. Here connections are made with the Florida East Coast Railway.

Titusville is a thriving town of about two thousand five hundred inhabitants, and is noted for its beautiful vegetable and fruit farms and its orange groves. **Merritt's Island,** almost opposite Titusville, is a long triangular island, comprising about fifty-eight thousand acres, mostly pine land, but noted for its pineapple plantations. The portion of the Indian River on the east side of the island is called Banana River, and is a great resort for fishermen.

Rockledge is a beautifully situated town on the west bank of the river, the trade centre for the superior quality of the oranges cultivated in its vicinity. Fishing and duck-shooting afford abundant recreation and amusement to sportsmen. Hotel Indian River here keeps sail and row boats and steam launches for the benefit of its guests; and daily excursions are made to Fairyland, City Point, Tropic, and other places of interest. Hotel rates, $4 and $5 a day; $22.50 to $25 and upward a week. The New Rockledge Hotel and The Plaza are good hotels, though less elaborate than the Hotel Indian River—at $2.50 and $3.50 a day.

Jupiter, at the mouth of Indian River, on Jupiter Inlet, the landing-place of the Indian River Steamboat Company, is an excellent winter resort for fishing and hunting. The climate is equable and enjoyable, the temperature ranging from 58° to 62° F. Carlin House and Miller House furnish accommodations at $2 a day, or $10 a week.

Palm Beach, on the eastern shore of Lake Worth, the terminus of the Jacksonville, St. Augustine, and Indian River Railroad, has recently been made one of the most attractive winter resorts of Southern Florida,

famed for its fishing and hunting advantages. It may be reached also *via* steamers of the Indian River Steamboat Company to Jupiter, thence by the Jacksonville and Lake Worth Railroad, and steamers on Lake Worth. The town is situated between the ocean and Lake Worth. The region around abounds in tropical fruits and flowers. The Royal Poinciana rivals the Ponce De Leon of St. Augustine in magnificence, elegance, and equipment. It has accommodations for one thousand guests. Rates, $5 a day and upward; special rates for the season. Cocoanut Grove House, Lake Worth Hotel, and Oak Lawn House are good hotels at from $2.50 to $4 a day, and special weekly rates; and there are boarding-houses at from $10 to $15 a week.

Miami, on Biscayne Bay, is the terminus of the Florida East Coast Railway, which skirts the east coast of Florida from Jacksonville south, and is the most southern of the well-equipped east-coast winter resorts. Semiweekly trips are made here by the Miami-Nassau Steamship Line during January; triweekly during February and March; and semiweekly during April, until the service terminates. The winter temperature here is equable and about 64° F. The vegetation is strikingly tropical, and the two excellent hotels, Hotel Royal Palm and Hotel Biscayne, display it to admirable advantage in their beautifully laid out and ornamented grounds. Biscayne Bay is a large sheet of salt water, so clear that its garden-like bottom and numberless fish can be plainly seen to a depth of twenty-five feet and more. It is separated from the ocean by the picturesque Florida Keys. There is open-air bathing in the bathing-pool in front of the Royal Palm at all times. Boating and canoeing on the rivers and into the Everglades, with steam-launch and sailboat excursions, are other attractions. Hotel rates, $3 a day and upward.

Winter Park, managed under the auspices of the Plant Railroad System, is situated at an altitude of over a hundred feet above sea level, in the midst of the lake and pine-forest region; about forty miles from the Atlantic coast, and eighty miles from the Gulf of Mexico, one hundred and thirty-three miles south of Jacksonville, and one hundred miles north of Tampa. The situation affords an excellent watershed and good soil drainage. The water of the lakes round about is said to flow from one to another. The average winter temperature is about 62° F.; the winter rainfall is slight, and the air relatively dry. The Seminole Hotel is an elegant establishment, equipped with all modern improvements; $3 to $4 a day. The bicycle and other roads are excellent, and the outdoor attractions enjoyable. *Ocala* is a flourishing business town of five thousand inhabitants, situated on the central ridge, about midway between Jacksonville and Tampa, on the Plant Railroad route to Key West. The high dry land is entirely free from malaria, and the refreshing breezes through the pines from the ocean and the Gulf combine to produce a mild and healthful climate—particularly commendable to consumptives, as is also Winter Park. The mean winter temperature is about 62° F., equable, and the air relatively dry—the rainfall during the winter months being small. The roads are good and the outings attractive. The Ocala House is commodious and well equipped with all modern appliances; rates, $3 to $4 a day.

Tampa Bay Hotel at Tampa, conducted by the Plant System, is an eminently luxurious house, with everything calculated to promote the enjoyment of the tourist. It is a fireproof structure, built upon the Tampa peninsula, open to the mild and equable climate of the Gulf, with spacious grounds ornamented with tropical verdure and flowers. The Casino, which adjoins the hotel park, fifty feet distant and midway between one of the hotel entrances and Hillsborough Bay, is a handsome addition to the means of enjoyment, provided as it is with a swimming-pool, fifty by seventy feet, with a depth of water varying from three to ten feet, surrounded by dressing-rooms, each with an outside window. A competent instructor in swimming, as well as ladies' maids, is in attendance during the season. The Theatrical Auditorium, one hundred and fifty-seven by eighty-eight feet floor space, with a seating capacity for an audience of two thousand, furnished with handsome opera chairs, is another Casino feature; and for this the proprietor announces that "a large number of the best theatrical companies are engaged and will appear at intervals during the season."

Alabama.

The winter climate of northern Alabama is both delightful and healthful. The temperature rarely falls so low as 32° F., the average temperature being about 50° F. **Huntsville** and **Florence,** on the Tennessee River, are justly favorite health resorts, with excellent accommodations at moderate prices.

Mobile, situated on a sandy soil on the western shore of Mobile Bay, with a thrifty growth of pine woods roundabout, through and by which the warm Gulf breeze is sifted of its excess of moisture, is also an excellent winter resort for people with tender lungs, and the better now by reason of the energetic sanitary measures recently practised on account of the fever, from which there is no longer any danger. Besides, on the eastern shore of the bay, from fifteen to twenty miles nearer the Gulf, **Alabama City, Williamsburg,** and **Point Clear** are well-appointed places, with good hotel accommodations, bathing and boating facilities, with cottages and orange groves roundabout, available for invalids or for pleasure seekers who would long sojourn and enjoy the attractions of fishing and hunting. The waters, fields, and forests are all alive with game.

Mississippi.

The bluff shore of the Gulf and Mississippi Sound, along which are situated Pass Christian, Ocean Springs, Bay St. Louis, Biloxi, Pascagoula, several smaller towns, and numerous villas, has long been deservedly noted for its healthfulness and is a favorite winter resort for invalids who would enjoy the warm and soft Gulf winds. Though these winds are sometimes loaded with moisture, the moisture is always *clean* and never liable to make people sick, like that which hovers over low and undrained soil. Their salutary effects on some of the more chronic forms of tuberculosis, particularly in aged persons, in nervous derangements and insomnia, are well attested by numerous cases. But it appears to have been the great misfortune of this locality recently that the authorities have neglected needful sanitary measures, insomuch as to have allowed opportunity for the epidemics of dengue and yellow fever. It may be said, however, as of Mobile and of New Orleans, that the condition has been greatly improved by reason of the energetic sanitary measures that have since been practised. There are good hotel and boarding-house accommodations in all the localities named, and other facilities for enjoyment.

Louisiana.

The northern and western sections of this State are generally healthful at all seasons; and the mild winter climate, which allows daily outdoor exposure, has long been recognized as being particularly beneficial to persons affected with or predisposed to pulmonary diseases.

New Orleans is one of the most enjoyable winter resorts in the country, and the more so by reason of the enforcement of sanitation on account of the fever. There is no day so cold and but very rarely

one so wet as to prevent open-air exposure, and there is no end to the attractions in and round about the city. Many of the old relics of Spanish and French rule still exist. Its French quarter and market are unique as objects of interest. Old Spanish Fort, on Lake Ponchartrain, five miles distant by electric cars, the originally undertaken site of the city—and now to New Orleans what Coney Island is to New York—is a daily novelty. Other places in the suburbs are the battleground of the famous victory of General Jackson over the British forces, January 8, 1815, and the still unfinished monument commemorative of the victory; Carolton, Gretna, Algiers, and many other localities of interest but a few miles distant, all accessible by excellent carriage roads, surface cars, or steamboat excursions. New Orleans has been so long famous for its opera, theatres, and, above all, for its "Mardi Gras," on Shrove Tuesday, when Rex, King of the Carnival, arrives, that to undertake a description of these enjoyments would be wholly superfluous as well as altogether inadequate. They should be seen and shared to be duly appreciated.

Arkansas Hot Springs.

These are situated in the town of Hot Springs, Ark., latitude 34° 5′ N., in the midst of a wild and picturesque mountain region, one thousand five hundred feet above the sea level, forty-five miles southwest of Little Rock, and six miles north of Wachita River. The town lies, principally, in the narrow valley of Hot Springs Creek, running north and south between the Ozark Mountains. It is embowered in trees and presents a very picturesque appearance. In the middle of the day it is sometimes very warm, even in winter, and the nights are cool; but the average winter temperature is about 50° F. The springs are in number seventy-one. They are chiefly chalybeate and sulphuretted. They vary in temperature from 76° to 157° F., and many of them have been improved. The waters are used internally and to a considerable extent externally; there is a large number of bathing-houses with vapor, douche, and plunge baths at various temperatures. The amount of hot water flowing from the springs into the creek renders it sufficiently warm for bathing in midwinter; the discharge into the creek is about five hundred and fifty gallons a minute. Their chief reputation rests upon their efficacy in the treatment of rheumatic and gouty affections, syphilitic and mercurial diseases, and certain forms of skin diseases. It is not a good resort for consumptives. Hotels are numerous and adequate, at from $2 to $5 a day, and $8 to $15 a week. Rates of travel: from New York, over the trunk lines, $32.40 to $35.40; from St. Louis by the St. Louis, Iron Mountain and Southern Railroad to Malvern, and thence by a branch road to the Springs (distance, four hundred and thirteen miles; time, about fifteen hours), excursion tickets, good for ninety days, $22.50.

"**Dry, warm air** is found in southwestern Texas, and the southern portions of New Mexico and Arizona." This was the deduction of Gen. A. W. Greely, chief signal officer, from a map illustrative of an article under the caption of "Where Shall We Spend our Winter?" contributed by him to *Scribner's Magazine*, for November, 1888.

Texas.

San Antonio, a city of over fifty thousand inhabitants, situated at an elevation of six hundred feet above sea level, between, or rather on, by reason of the recent expansion of the city, two rivers, the San Antonio and the San Pedro, latitude 29° 30′ N., possesses a mild, dry, and equable winter climate, commendable to consumptives. It is, however, subject to occasional high winds and dust, which should be avoided. It is a progressive city, and enjoyable because of its excellent hotels, churches, opera house, and other social attractions; a large preponderance of sunshiny days, good roads round about, and conditions inviting to outdoor life. It is two hundred and ten miles west of Houston by the Galveston, Harrisburg, and San Antonio Railroad, of the Southern Pacific system; one hundred and thirty-five miles from the Gulf of Mexico by the San Antonio and Aransas Pass Railroad; eighty-two miles from Austin by the International and Great Northern Railroad, and one hundred and fifty miles by rail from the Rio Grande at Laredo.

Boerne, a small town thirty miles northwest of San Antonio, on the San Antonio and Aransas Pass Railroad, at an elevation of one thousand five hundred and fifty feet above sea level, has a climate very similar to that of San Antonio; average winter temperature, 62.7° F.; mean relative humidity, 69. Severe "northers" sometimes occur during the winter, when there is a fall in the temperature of from five to twenty degrees, for a few hours, or for a day or two. There are no hotels of consequence here, but there are good boarding-houses at from $20 to 40 a month; and commonly, plainly furnished houses may be rented at from $10 to $20 a month. There are very few days during the winter which are prohibitive of outings. The roads are good, and there are many attractions in the way of driving, hunting, and fishing.

El Paso, a city of eleven thousand inhabitants, situated at an altitude of three thousand seven hundred and sixty-four feet above sea-level, in the extreme northwestern corner of the State, in latitude 30° 47′ N., has a mean winter temperature of about 46° F., but there is great variation in the day and night temperatures; at midday the temperature often rises to 60° F. and at night sinks to freezing. The winds are moderate and the atmosphere is cloudless. Mean winter rainfall, 0.65 inches; mean relative humidity, 56 per cent. There are several good hotels here and pleasant social attractions. Wheeling and driving on good roads, and mountain climbing are the out-door attractions.

New Mexico.

Las Cruces, a small town situated at an altitude of three thousand eight hundred feet above sea level, in the southern portion of the State, on the line of the Atchison, Topeka, and Santa Fé Railroad, has an average winter temperature of about 43° F., and a relatively dry atmosphere, with a large proportion of sunshiny days that admit daily outings. The attractions are interesting drives, shooting, and Mexican curios. There are no hotels of note here, but there are good boarding-houses, among them those of F. C. Baker, R. C. Halton, J. R. Schmidt, K. Livingston.

Arizona.

Phœnix, situated at an altitude of one thousand two hundred feet above sea level, in the Salt River Valley, with a branch connection with the Atchison, Topeka, and Santa Fé Railway, occupies about the same parallel of latitude as San Antonio, and possesses a similar climate, with the additional advantage of greater altitude, but greater liability to dust. The valley is about sixty miles long by twenty wide, protected by high mountains. The average winter temperature is about 60° F., and the atmosphere exceptionally dry. Phœnix is reported to be well equipped for the entertainment of visitors.

California.

The improved health resorts of California are almost wholly confined to the seacoast; and the winter resorts in Southern California are only those between Monterey and San Diego.

Monterey, situated on the southern extremity of a

bay of the same name, seventy-eight miles south of San Francisco by water, and two hours distant by rail, latitude 36° 37′ N., has an equable mean winter temperature of 52° F.; the atmosphere is humid.

The peninsula on which the town lies affords views of the bay and the ocean and beautiful scenery round about. The *Hotel del Monte* is one of the largest and most luxuriously furnished hotels in the State. The grounds consist of a beautifully ornamented park of one hundred and twenty-six acres, a mere corner of an area five times larger, containing groves of native trees and shrubbery. There are good roads for wheeling and driving, boating and fishing paraphernalia in short, everything calculated to promote the health and comfort of guests. The rates are $4 a day and upward. There are, besides, several other good hotels at $4 and less.

Santa Cruz, across the bay, opposite Monterey, and with a climate about the same, has the advantage of a beautiful bathing-beach, about a mile from the centre of the town. There are good bathhouses and everything necessary to the comfort and enjoyment of bathers. It is a beautiful town and the scenery round about is most enjoyable; and for this *Sea Beach Hotel* affords every facility. It is easily reached from all points by horse cars and electric cars from neighboring localities, and the Southern Pacific Railway station is only a short distance off. The rates are moderate.

San Jose, the New Haven of the Pacific, a town of twenty-two thousand inhabitants, is situated in the valley of Santa Clara, one hour and twenty minutes by express trains from San Francisco, and in close connection by frequent trains with Santa Cruz, Monterey, and Pacific Grove. The valley of Santa Clara, in which San José is located, is fourteen miles wide. To the east are the hills of the Coast Range, the highest summits rising to the height of five thousand feet above sea level; to the west the Santa Cruz ranges, four thousand feet high, showing through the blue haze dark green forests on a background of golden light. The sanitary works are excellent, and the records show a corresponding healthfulness of the town. *The Hotel Vendome* is a commodious and well-furnished house, only a few minutes' walk from the Southern Pacific Railway depot. The street cars pass the door at short intervals. It furnishes every facility for the enjoyment of the magnificent scenery with which the town is surrounded.

Pacific Congress Springs—so-called because of the alleged resemblance of the waters to those of Saratoga, N. Y.—are situated ten miles west of San José, near Saratoga, at an elevation of seven hundred feet above sea level, amid picturesque scenery. The chemical elements of the waters, as shown by analysis made by Dr. Winslow Anderson, are as follows:

The Pacific Congress water contains 304.07 grains of solid matter to the gallon, consisting of:

Sodium chloride	115.70
Sodium carbonate	120.42
Sodium sulphate	12.95
Potassium carbonate	2.06
Magnesium carbonate	26.34
Magnesium sulphate	4.19
Ferrous carbonate	13.87
Alumina	4.50
Silica	3.98
Total	304.07
Organic matter	trace.
Gases—free carbonic acid	14.17

The springs have been improved, and have the advantage of being a popular winter as well as summer resort.

Congress Hall consists of a spacious main building, with broad veranda, and a number of two-story cottages adjoining, grouped upon a plateau on the mountain side, and surrounded by shade trees, a beautiful lawn, and rare tropical plants and flowers. The surroundings make one feel that there are plenty of room and comfort everywhere. There are bathrooms convenient to the hotel, where hot and cold baths are served.

Good hunting and fishing, as well as romantic drives, add to the reputation of the springs. Board, $2.50 a day, $10 to $15 a week.

Santa Barbara is a town of eight thousand inhabitants, two hundred and seventy-five miles southeast of San Francisco, by steamer or by Southern Pacific Railway. Latitude, 35 N.; mean winter temperature, 54 F.; mean humidity, 73. But to compensate for its humidity it possesses the special advantage of altitudes ranging from almost sea level to thirty-five hundred feet above, with a corresponding change of atmospheric conditions. If the damp atmosphere of the coast is found to disagree, relief may be obtained by going back from two to six miles among the foothills, where there are numberless sheltered nooks, or a little farther into the cañons of the mountain side, where the air is warmer as well as drier. Few winter health resorts possess a better or a more deserved reputation as desirable localities for consumptives than does Santa Barbara. The hotel accommodations are adequate and excellent.

Moreover, about six miles northeast of the town are the *Santa Barbara Hot Springs*, picturesquely located at an altitude of fourteen hundred and fifty feet above sea level, amid the forest-covered mountains. There are about thirty of these springs—sulphurous, saline, and chalybeate—ranging in temperature from 99 to 122° F. Seven of the principal ones are used for drinking and bathing purposes. They have considerable reputation in the treatment of rheumatism, gout, Bright's disease, liver affections, and bladder irritation. There are hotel and bath accommodations.

Los Angeles, sixty miles south of Santa Barbara, a city of over one hundred thousand population, is situated on Los Angeles River, thirty miles from its mouth, at an altitude of three hundred and thirty feet above the sea. It is a beautiful and interesting city. Its proximity to the mountains insures an abundant supply of pure drinking-water, and the sanitary works are excellent. The mean winter temperature is about 53° F., with but a slight range. The percentages of cloudy and sunshiny days, and the number of clear days in winter, as recorded, are, respectively, 34, 66, and 49. The delightful climate, excellent roads, and beautiful scenery all lend their attraction to open-air enjoyments. It seems almost needless to say that the hotels are abundantly adequate and well equipped, and the rates are moderate.

Pasadena, situated at the base of the Sierra Madre Mountains, on the line of the Southern California Railroad, ten miles northeast of Los Angeles and five hundred feet higher, possesses a delightful climate. It is a flourishing town of about six thousand inhabitants, has steam and surface railroad connections for many miles round, and excellent roads besides; which, with the beauty of the scenery and many objects of interest round about, are constant incentives to open-air enjoyment. The *Raymond* and *Carleton* are both good hotels at moderate rates.

San Bernardino, a delightful inland resort, with about five thousand inhabitants, lies in a picturesque valley about sixty miles east of Los Angeles, in the mountains. It is reached from Los Angeles by the Southern California Railroad in two hours. It is embowered in fruit and ornamental trees, and the choicest of California fruits of all kinds are produced hereabout in great abundance. The air is much drier than that of places on the coast, and in so far is more commendable to some consumptives. Its delightful temperature, lovely weather, and the beauty of

the scenery are a perpetual inducement to open-air life. There are several excellent hotels at moderate rates.

San Diego, situated on the bay of the same name, four hundred and sixty miles southeast of San Francisco and fifteen miles north of the Mexican border, latitude 32° 44′ N., is a city of about twenty thousand inhabitants, and, next to that of San Francisco, has the best harbor on the California coast. The town is more than one hundred years old, but it is only during recent years that the sanitary works have been such as to render the town attractive as a winter resort, and recently much progress has been made. The soil in the higher portions of the town is sandy; the mesas or tablelands ascend from the bay until they reach the mountains, about forty miles distant. Hence the natural facilities for drainage are good, excepting for some low and marshy ground around the shores of the southern end of the bay, and have been turned to advantage. Some forty to fifty miles of sewerage pipes have been laid, and a pure water supply, brought from the mountains, has been introduced within the last ten years. The best residential portion of the town is Florence Heights, one hundred and eighty feet above sea level, where there are many beautiful houses with charming grounds.

The climate is remarkably equable and dry for a seacoast place, the annual range of temperature being but fifteen degrees; the mean winter temperature is about 54° F., from which it rarely varies more than five degrees. Relative humidity, 73 per cent. Frost is unknown here and the lowest temperature on record is 40° F. The average annual rainfall is ten inches—about one-third of it during the winter months. The breeze is almost constant but moderate, and a fog exceedingly rare.

Directly opposite San Diego, across the bay, one mile distant and with steam-ferry connection, is **Coronado Beach,** a crescent-shaped tongue of hard sand, six miles long, which separates the bay from the ocean, bearing some resemblance to Cape May.

These—San Diego and Coronado—are "Our Italy," of which Charles Dudley Warner wrote so admiringly, after spending a part of the winter there in 1889–90. "It lies there, our Mediterranean region, on a blue ocean protected by barriers of granite from the Northern influences, an infinite variety of plain, cañon, hills valleys, seacoast—our new Italy, without malaria and with every sort of fruit which we desire, except the tropical, which will be grown in perfection when our knowledge equals our ambition; and if you cannot find a winter home there, or pass some contented weeks in the months of Northern inclemency, you are weighing social advantages against those of the least objectionable climate within the Union. It is not yet proved that this equability and the daily outdoor life possible there will change character, but they are likely to improve the disposition and soften the asperities of common life. At any rate, there is a land where, from November to April, one has not to make a continual fight with the elements to keep alive."

The Hotel del Coronado, on Coronado Beach, is one of the most commodious and luxuriously equipped hotels in the Union. It covers seven and one-half acres, surrounded by a park of ornamental trees and flowers of unsurpassable beauty. Its chief rivals are the *Horton House*, *Florence Hotel*, and *Brewster House;* and *St. James Hotel*, at San Diego, on the other side of the bay, though less elaborate, is of equal elegance with the Coronado. The rates are from $3 to $5 a day.

Of attractions to outdoor life there is no end in the beautiful scenery and places of interest, accessible by wheel or carriage on good roads, steam and surface cars, and steamboat excursions—so versatile and so interesting as to be a constant inducement to healthful recreation in the open air.

San Diego is the western terminus of the Atchison, Topeka, and Santa Fé system. Its connection with San Francisco is by steamer or the Southern Pacific *via* Los Angeles.

Through tickets are on sale at San Francisco, Oakland, Alameda, and San José, reading to Lompoc, Santa Barbara, and Los Angeles, and other points; also at Los Angeles, Sant Barbara, and Lompoc, reading in the opposite direction. The rates are as follows: Between San Francisco and Lompoc, $10.90; between San Francisco and Santa Barbara, $15; between San Francisco and Los Angeles, $18.35. Between San José and Lompoc, $9.65; between San José and Santa Barbara, $15; between San José and Los Angeles, $18.35.

The Sandwich Islands.

With the geography of these islands in detail the tourist is supposed to have made himself acquainted from other sources. They lie in latitude 21° 18′ N., and longitude 157° 55′ W., twenty-one hundred miles from San Francisco. The Ocean Steamship Company's steamers make the voyage fortnightly; also those of the Pacific Mail Steamship Company, and the Occidental and Oriental Steamship Company. The usual time from San Francisco to Honolulu is six days. Fare, $75: round trip, good for four months, $125.

Though these islands are on the verge of the tropics and over two thousand miles distant from other land, the climate is virtually an exaggeration of that of the seacoast rather than oceanic. This is probably due to the nature and conformation of the soil, the enormous amount of vegetable *débris*, and the great rainfall.

There are twelve islands in the group, all of volcanic origin, differing in altitude from ocean level to fourteen thousand feet above. Besides the two peaks of the principal island, Hawaii, Mauna Kea and Mauna Loa, each of which is fourteen thousand feet high and one of them covered with perpetual snow, this island is traversed by many other rugged and craggy peaks and ridges, and presents a magnified view, as it were, of the same characteristics more or less common to the other islands of the group. Several of them, or at least large portions of several of them—particularly on the windward sides—are covered with dense forests. The rough crevices and culs-de-sac are literally stuffed with the *débris*. The annual rainfall is from one hundred and forty to one hundred and fifty inches, and in consequence of the obstructed surface drainage and the high temperature the accumulated *débris* is kept in a state of constant decay and the climate rendered malarious. Moreover, by reason of the elevated peaks and ridges and the thick forests on the windward sides of the islands, the circulation of the air is impeded and the benefit which otherwise would be derivable from the prevailing trade wind from the northeast is lacking. Hence the winter temperature of these islands, according to the records, instead of being oceanic and equable at about 80° F., is about 70° F. and *variable*—the diurnal variation in winter being from ten to fifteen degrees, and the annual range from 53° to 90° F. The sea voyage from San Francisco is commendable, but as a health resort Hawaii does not compare favorably with those on the seacoast of Southern California.

Intussusception.—Under anæsthesia a rectal tip was inserted, which controlled any escape of water from the rectum, and through it over two gallons of water was introduced into the bowel. There was a sudden violent gush of water from the patient's mouth, showing that the obstruction was overcome.—Pynchon, *Matheze's Medical Quarterly*, January.

NASSAU AND THE BAHAMA ISLANDS.

BY OLIVER J. D. HUGHES, PH.D., M.D.,

[illegible], CONN.,

EX-VICE-PRESIDENT, CONNECTICUT MEDICAL SOCIETY; LATE [illegible], NEW HAVEN COUNTY MEDICAL ASSOCIATION; [illegible], MEDICAL [illegible] ASSOCIATION.

How often we tell a patient that a change of climate is necessary—is, in fact, imperative to save life—and then deliberately send him to some place which is in every way unfitted for his diseased condition! Now, after a thorough acquaintance with Nassau and the Bahama Islands since 1875—that is to say, some two-and-twenty years—I think I can with some knowledge and authority speak for what Nassau can do for a certain class of cases; or, in other words, what special diseases may be and are benefited by a longer or shorter sojourn there.

I might say, at the start, that I am no great believer in sending patients *in articulo mortis* to any place but their own home. Such patients will not improve anywhere; let them die in peace and comfort, at home among their friends and relatives.

The Bahama Islands lie a few hours' sail from the eastern shore of Florida, with the Gulf Stream winding its way among them, keeping up a dry, pleasant heat, which never becomes oppressive, owing to the ever-blowing trade winds—the average winter temperature being between 70° and 80° F. during the day, and at night everything is cool, with no mosquitoes or other members of the flying world to disturb pleasant or healthful dreams. Doors and windows nobody shuts either by day or night, as the air will do good, "and thieves do not break through nor steal."

But to come down to the cases benefited by residence in this group of islands:

1st. All cases of acute or semi-acute affections of the lungs.

2d. All cases of nervous afflictions, including most especially those of a diabetic character.

3d. Rheumatic cases in all their chronic and semi-chronic conditions.

4th. All classes of patients recovering from severe forms of any of the acute diseases.

5th. It is the only place in the world for a tired-out professional or business man to take it easy, and really do nothing but enjoy himself quietly and give nature a chance to build up and once more make a man able to do man's work.

6th. That class of stomach troubles found so often among business or professional men and women who bolt their meals and then rush off to work again; that class of cases in women who are so constipated that they never have a natural movement of the bowels.

In the first class mentioned—affections of the lungs—so long as they are not in the last stages, where can you find such a perfectly dry sea air, thoroughly loaded by nature with everything necessary to repair broken-down tissue and build it up anew, sound and healthful? The wife of one of America's greatest painters was kept alive for over twenty years by being brought down every winter. A great many times I have seen her carried aboard the steamer at New York on a Thursday afternoon, and on the next Monday morning seen her walk ashore at Nassau almost a new person.

Another case: the beautiful wife of a prominent New York lawyer, who if she stays in New York City during the winter at once develops a well-marked bronchitis which more than once has nearly carried her off, finds instant relief in the fair Isle of Irme.

A medical friend of mine, now enjoying a large practice in one of our Southern cities, came to me some years ago for advice as to what he should do. On examination I found his right lung very much broken down. He had previously seen nearly every prominent lung specialist in the country, and had been advised to go from Maine to California. He had done so, with the result that he had gotten steadily worse—to say nothing of a pocketbook nearly empty. He wanted advice as to what to do. His stomach had arrived at that point where food and medicine were almost rejected before being swallowed. I advised him to go and live on one of the out-islands of the Bahama group, to leave all medicine alone, and to feed on the flesh of the green turtle, with plenty of baked plantains in place of bread, and some good rye whiskey to take the place of all opiates. He did as I advised, lived strictly as ordered, was outdoors all day long, even sleeping at night with only a shed over him, bathing every day in the warm salt water. He gradually improved, until after living thus for eighteen months he came back to the United States a well man, hearty and able to do a good day's work, to enjoy three square meals a day without distressing his digestion in any way. He had been cod-liver oiled almost to death before starting for the Bahamas—with what result? His lungs steadily getting worse and his digestion ruined. Now mark the difference. Under a good liberal diet of fresh turtle flesh—which contains ten to one more nourishment and tonic properties than any bad-smelling and worse-tasting cod's-liver product—he picks up, is able to enjoy his food, and nature gets a chance to repair his diseased lung tissue. Oh! when will we learn to appreciate nature's rare gifts and to keep from doing harm just from force of habit and because our grandfathers blundered at the start! I can recall a great many other cases, but I think the above are enough.

In the second class—nervous affections—the climate seems to have a soothing, quieting effect, which, combined with the complete change in the ways and manners of life, helps to take the patients' thoughts away from themselves and thus improve their nervous system.

For the diabetic, where can he find a place so well suited for him? As near the sea level as he can get without walking directly into the sea; a climate such that he can be outdoors day and night; with the greatest variety of fish diet, with acid fruits in profusion, with the skin-baked banana food, as near a non-starchy substitute for flour as can be found.

Thirdly, that class of chronic rheumatic cases so often found in our Northern cities and villages. The crippled fingers and feet seem to improve and grow limber once more under the influence of the life-giving air and warm salt-water baths.

Fourthly, any one who has been flat on his back, after a severe attack of any kind of acute sickness during a Northern ice-bound winter, improves rapidly. What with the complete change of climate, food, habits of life, etc., two weeks out there will do more good than three months of tonics.

Fifthly, how often we are called to see a business man who is said to be suffering from "malaria," or "nervous prostration," or some other thing which means the same—"nothing." Why not use good, plain Anglo-Saxon and say that he is "played out" from overwork or something else? To this class a two or four weeks' trip to these beautiful isles, with their easy-going, happy-go-lucky ways, brings new life. One is able to see the funny side of life once more, to laugh, be merry, and grow fat and be happy. Can medicine alone do this? I think not.

Sixthly, we come to the man and woman who have arrived at that stage of life on earth when the pleasures of the table are a thing of the past, who can only

groan and look sour when they see anybody else enjoy a good meal, who travel around with a large and well-assorted case of every drug in the materia medica—to say nothing of half a dozen bottles of So-and-So's digestive fluids. To these people—who know more or think they do than all the medical profession in the world—I say: Throw away your patent medicines, go to "those blessed islands" of Columbus, drink of nature's greatest remedy—"pineapple juice," fresh and sweet—live temperately, avoid highly spiced foods, and be cured.

Just one word concerning the constipated woman, who has to take "physic" every day of her life. Try on her the effect of a trip to Nassau, and, instead of the usual amount of cathartic medication, just let her drink a quart of fresh pineapple juice during the day.

The people and government officials of Nassau will be found obliging and willing to serve strangers in every way. There is no formality; hospitality abounds on every hand, from the rich Nassau merchant to the poor humble "colored brother" at Grantstown. No pen can describe the quaint sights or funny sayings to be seen and heard among these primitive descendants of captured blacks liberated from Congo slave ships. I have never yet seen a person who has once been to these islands but wishes to return once more to them for just one more happy stay among these contented, happy islanders.

Living is cheap comparatively; the hotels and boarding-places are clean, neat, and pleasant. Outside expenses need not amount to very much.

How to get there is simple and easy. Take one of the handsome and well-equipped steamships of the New York and Cuba Mail Steamship Company (James E. Ward & Co., 113 Wall Street, New York, agents), some cold, sleety, disagreeable Thursday afternoon this winter, from Pier 17, East River, and after a pleasant life-giving sea voyage of four days—during which you have been fed like a nabob and lodged like a lord—you are landed at Nassau the following Monday morning; or, if you are a poor sailor, go *via* a "Florida special" to Miami, and take the Flagler Line steamer direct to Nassau. But whichever way you go, when you start to come back you will leave good, quaint, old Nassau with many regrets.

One word in closing for the medical profession as found in Nassau. Without any exception, they are well-read, busy, good fellows, always glad to welcome a visiting professional brother and to do anything to make his stay among them pleasant in every way.

THE ASHEVILLE PLATEAU IN THE MOUNTAINS OF WESTERN NORTH CAROLINA.

BY S. WESTRAY BATTLE, M.D., U.S.N.,

ASHEVILLE, N. C.

HAVING received so many inquiries for a brief outline of the climatic conditions which prevail upon what I have chosen to call the Asheville plateau, a summary of the advantages of the region may not be out of place.

It is a common thing in this life that the harder a thing is to acquire the more desirable it becomes. The same proposition obtains in the matter of climate: the more inaccessible a place, the more virtues it possesses. It seems to me that the profession has not given to this region the attention it merits—a most desirable and beautiful section of country, in close touch with the East and North, and most accessible from all points South and West.

Nestled in the heart of the Alleghanies, cradled by the Blue Ridge and Great Smokies, stretches the Asheville plateau, the great sanatorium of Western North Carolina and Eastern United States. It enjoys a climate *sui generis*, representing the golden mean of altitude and latitude and the several meteorological conditions which go to make up a wholesome and fascinating resort. Nowhere east of the Rocky Mountains is to be found anything approaching it for fall and winter, spring and summer—an all-the-year-round retreat. It is cool in summer, yet the winters, shorn of their harshness by reason of its southern latitude, induce almost daily outdoor exercise in the way of shooting, riding, driving, or short mountain excursions on foot. For lovers of golf it is ideal: and at Asheville, the centre of the plateau, are united the comforts of a city with the delights of the country.

The plateau is an elevated tableland, somewhat triangular in shape, embracing some six thousand square miles of Western North Carolina, with a general elevation of two thousand feet above the sea level, though altitudes up to six thousand feet may be had for the climbing any day in the year. Hills, valleys, rivers, and forests so diversify this intramontane expanse as to make it lovely and restful to the eye, beyond the power of my pen to portray.

The temperature is indicated by the following table: Mean temperature of spring, 53.49° F.; summer, 70.72° F.; autumn, 53.48° F.; winter, 38.87° F.; for the year, 54.14° F.; with a mean relative humidity of 65 per cent.

There can hardly be room for controversy that right here we are enjoying the golden mean of American climate. With medium altitude, dry, tonic, invigorating, and ozoniferous atmosphere, the region cannot fail to grow in popularity as meeting the indications in the cases of a large majority of health seekers, more especially those looking for the all-the-year-round residence; and it has occurred to the writer that it should particularly appeal to the retired of the army and the navy, and to him of modest independence, who wants to enjoy his *otium cum dig.* away from the busy whirl of the city and carking care. Nor is it amiss to mention that the finest private residence in America has been built here. With good roads and inviting inns, the shadows of which are now upon us, its attractions will vie with the now popular mountain regions of Europe.

In regard to the merits of the climate, or the climatotherapy of the plateau, let me briefly sum up its advantages without bestowing indiscreet or overzealous praise. It is pre-eminently a suitable one for the early stages of pulmonary phthisis, especially for such subjects as can and will get out in the air, and are determined to take the benefit of the dry, tonic, invigorating, bracing qualities thereof, and keep good hours. Conditions which seem to favor germ propagation and prolong the species of the genus bacterium do not exist here. Wounds heal kindly and operative procedures of the gravest character are rarely followed by septic infection.

The mortality from pulmonary phthisis is not large in any part of North Carolina, being, according to the mortality tables of the tenth census (1880), 13.4 for every 10,000 of population throughout the State. But it is interesting to note that the mountain counties show a mortality of only 10.6 in every 10,000 of population, as against 16.1 for every 10,000 of population of all the other counties of the State in the aggregate; or in other words, in a State where pulmonary phthisis does not figure prominently in the mortality tables the death rate is still fifty per cent. less in the mountain section than in the other lower-lying portions of the State.

Among other conditions indicating the advisability of a sojourn in this region may be mentioned asthma, hay fever, convalescence from malarial and other fevers (there are no lakes or swamps, and malaria is unknown), nervous prostration, and exhaustion from

overwork or long-continued summer heat; as also chronic congestion of the internal organs by reason of diminished atmospheric density causing a determination of blood to the surface—hence arises one of the benefits of altitude in incipient phthisis. Nervous energy and muscular vigor are usually increased, and the nutrition of the body and the general condition of the blood improved by a sojourn at moderate elevation; above six thousand feet the appetite for food is diminished and the digestive organs are frequently disordered, whereas a medium altitude usually increases the desire for food and quickens digestion. By reason of its medium altitude contraindications to a residence upon the plateau are few, though organic disease of the heart, in which the circulation is much disturbed, must not be lost sight of. Of course those who are in advanced phthisis, and are too feeble to breathe the outdoor air and take some sort of outdoor exercise, are better off at home with their friends, surrounded by comforts that cannot be supplied elsewhere.

Since the above was written, Surgeon John W. Ross, who retired from active service in the United States navy in 1894 on account of retinitis, has returned from a visit of inspection and careful study of certain of the veteran tuberculous sanatoria in Germany, particularly those at Falkenstein in the Taunus, and Reiboldsgrün in Saxony, where such admirable results have been and are still being obtained; as well as the more recently established institutions at Ruppertshain and Albertsberg for the cure of the poor afflicted with phthisis. Dr. Ross returns convinced that the climatic conditions of the Asheville plateau are the most favorable, all the year round, that he has ever experienced for the cure of patients afflicted with tuberculosis; and that a properly constructed, equipped, and conducted sanatorium here would give better results than those obtained in Germany.

The doctor's opinion is of value, for while in active service in the navy and since his retirement he has given special attention to the study of pulmonary tuberculosis with special reference to its climatic and hygienic treatment, having visited many of the best and most popular consumptive resorts in the United States, South America, and Sandwich Islands, besides those of the Old World; nor has this conclusion been reached hastily, as he had occasion to spend months here several years ago.

THE URGENT NEED OF SANATORIUMS FOR THE CONSUMPTIVE POOR OF OUR LARGE CITIES.*

By S. A. KNOPF, M.D. (Paris and Berl.), N. Y.

[illegible] NOSE HOSPITAL; FORMERLY ASSISTANT PHYSICIAN TO PROFESSOR DETTWEILER [illegible] ICAN ACADEMY OF MEDICINE; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, ETC.

THE question what to do with the thousands of tuberculous patients who inhabit the tenement districts of our large cities, unconsciously disseminating the germs of their diseases among their own kin, friends, and neighbors, or who crowd the wards of our general hospitals to the detriment and danger of the patients suffering from acute diseases, has become for the sanitarian one of the vital issues of the day.

In Europe such men as von Leyden, of Berlin;[1] von Schroetter, of Vienna;[2] Grancher[3] and Letulle, of Paris;[4] Weber, of London;[5] and in this country Biggs and Prudden, of New York;[6] Bowditch[7] and Otis,[8] of Boston; Flick,[9] Hinsdale,[10] and Lee,[11] of Philadelphia; Hamilton, of Chicago;[12] and many others[13] believe the only solution to be the erection of special sanatoriums,* preferably under municipal control. I myself have pleaded for sanatoriums for the consumptive poor on previous occasions,[14] and I now renew my plea before you, wishing to show again the urgent need for such institutions.

In Europe the pleadings of the profession for establishments of this kind have not been in vain; Germany alone can boast of over thirty sanatoriums for the consumptive poor, already in working order or in the course of construction, most of them under municipal control.[15] In the United States there are only two or three, partly supported by private charity, and not one institution which we may justly call a municipal sanatorium for the consumptive poor. Only recently we of New York and you of Pennsylvania have had the painful experience of seeing the chief officers of our respective States veto appropriations intended to create institutions which might have become the nucleus of more efficient work than has ever yet been accomplished in the United States in the extermination of this dread disease.†

Far be it from me to criticise the action of these distinguished governors, who thought to serve their State best by vetoing an appropriation which seemed to them unnecessary.

To convince them of their error, to convince the many of our fellow-practitioners who also deny as yet the need of special institutions for the consumptive poor, to show to the philanthropist a most practical and noble way to do good, not only to the consumptive individual but indirectly to the whole community—I will ask them all to accompany me for a moment on a little excursion to the crowded tenement district of one of our large cities. Let them visit there with me some of the consumptive poor who live in these houses, in all the various stages of the disease, from the incipient case of pulmonary tuberculosis to the last hectic stage of consumption, with all its pitiful manifestations of the slow ebbing away of human life.

Let us leave our comfortable homes, and enter the narrow streets of those districts, crowded with humanity. We make our way into a house through the little world in rags playing on the sidewalks. The hallways are dark, and the odor indicative of crowded and unclean rooms greets us. We ascend one or many flights of stairs, in the rear or in the front—it makes little difference. There lives Mr. So-and-So, with his wife and several children. They occupy two rooms, rarely three; but only one receives direct light and air. And in these few rooms live, cook, eat, sleep, and often work from eight to ten human beings.

We inquire after the patient, and find him lying on a couch or bed in a dark bedroom. We examine him, and find him suffering from pulmonary tuberculosis in the last stages. On examining the other members of the family, we find one or two of them already "touched" by the deadly germ.

In an audience of sanitarians there is no need to explain how the other members of the family have been infected. But I invited to my excursion some

* Read at the twenty-fifth annual meeting of the American Public Health Association, held in Philadelphia, Pa., October 26–29, 1897.

* Contrary to the custom of many English-speaking people, especially in the United States, I call these establishments *sanatoriums* and not *sanitariums*. The former, from *sanare*, to heal, gives a better equivalent to the German "Heilanstalt," the word used by the originator of this system (Brehmer). Secondly, the word sanitarium, from *sanitas*, health, is usually employed to designate a place considered simply as especially healthy, a favorite resort for convalescent patients.

† A decidedly different view must have been taken by the chief of a European State. At the recent twenty-fifth anniversary of King Oscar's accession to the throne of Sweden, a deputation presented him with the sum of 220,000 crowns, which amount had been raised among the people. He accepted the gift, but decided that the entire sum should be devoted to combat tuberculous diseases.

distinguished laymen, and to them I must briefly explain how one tuberculous individual is capable of transmitting his disease to whole families.

A consumptive expectorates at times as many as seven billions of bacilli in twenty-four hours. If the sputum containing these germs is not properly disposed of; if it has had a chance to dry on the floor, in a handkerchief, on the clothing, linen, or the beard of the patient—it will sooner or later become pulverized and be inhaled as dust by the other members of the family. If these are vigorous and well nourished they need not fear a contamination, for in health our nasal mucous membrane has a most marked bactericidal function. But, alas! very many of the inhabitants of these tenement districts are underfed, and their unhygienic surroundings are ill adapted to increase their power of resistance to disease. It seems also not improbable that at times the bacilli floating on particles of dust in the air are deposited on the food, and thus the germs are ingested.

Numerous experimenters, such as Falk,[16] Wesener,[17] Straus, and Wurtz,[18] have shown that the gastric juice has little power to destroy the bacillus of tuberculosis, and thus if the blood, which in health is phagocytic, is of poor quality, its corpuscles will not be able to swallow the ingested bacilli. If the victim be a child, these will find the best medium for multiplication in the delicate intestinal epithelium. If it be an adult, the bacillus will find an easy abiding-place in the apices of the lungs through the lymphatic and circulatory systems.

The weakest members of the family soonest fall victims to the disease. Fresh pure air and good healthy food, which are after all the best microbe killers, are lacking in the homes of most of these unfortunates, and thus the propagation of tuberculosis is most terrible in the tenement districts.

Compassion moves us, and through our efforts we procure a bed in one of the general municipal hospitals for the unfortunate sufferer. (Most of our hospitals supported by private charity refuse admission to consumptives.) He bids good-by to his loved ones. He is taken in an ambulance to the nearest municipal hospital. There are no special wards for consumptives, and the patient is placed in one of the general wards. His neighbor to the right may have typhoid fever; the one to the left a pleurisy *a frigore;* opposite him may be a rheumatic or a fellow-consumptive. If the physician in charge is in favor of medication, the patient will receive the latest remedies well spoken of in the treatment of tuberculosis. If the doctor is sceptical as to the value of medication in this disease, the patient may or may not receive the special diet, and the rest is left to nature. In the morning, before the arrival of the visiting physician, the poor consumptive inhales the dust, and with it countless numbers of pathogenic micobes, raised by the attendant sweeping the ward with an ordinary broom instead of wiping the floor with a moist mop. If the patient has not yet his mixed infection, he will soon get it. The consumptive in our general hospitals is almost as much deprived of fresh pure air as he has been in his home. Should he, day or night, ask to have a window open, his rheumatic neighbor would very strenuously object, for he could not stand the draught. Respiratory exercises are but rarely recommended, for the physician knows that they are useless in the ordinary hospital atmosphere. At meal times the consumptive patient eats but little. The frequent anorexia he cannot overcome, and even the special diet does not tempt him. The aerotherapeutic and hydrotherapeutic measures, so largely and beneficially resorted to in sanatoriums and special hospitals to overcome the loss of appetite, cannot be carried out in a general hospital. At night the patient sleeps but little. He is kept awake either by his own cough or by that of his neighbor. The stuffy night atmosphere of the ward furthers still more his hyperidrosis. Thus he passes weeks, sometimes months, until a fatal termination ends his sufferings.

We must leave our consumptive friend to his fate in the hospital, and return once more to his family at home. There we find most likely that they are in want, their supporter having been sick for months. In the majority of cases such a family is bound to become a public charge in the end.

This is the average condition of the consumptive poor in our large cities, and the general practitioners present will find that the picture I have drawn of the life of the tuberculous patient without means, at home and in the general hospital, has not been a fictitious one.

How can it be changed? There are in New York about ten thousand consumptives without means, and all other large cities of the union have an equal proportion.

What can the creation of sanatoriums do, in face of such appalling numbers? Seemingly little at the beginning, but much good in the long run.

Would the maintenance of a consumptive patient in a sanatorium or special hospital in or near a large city be more expensive than in a general hospital? I will answer this question by a few recent statistics which I have gathered for this purpose.

According to the last annual report of the board of commissioners of charity and correction of the city of New York, the highest daily expense per patient (in Fordham Hospital) was $2.06, the lowest daily expense per patient (in the City Hospital) was thirty-three cents, and the average expense per day per patient for all the municipal hospitals of New York is $1.16. The daily average expense in the most luxurious and most modernly equipped sanatorium for consumptives, the Loomis Sanatorium, under the able direction of Dr. Stubbert, is $1.43. The Adirondack Cottage Sanatorium, which, through the untiring effort of its distinguished director, Dr. Trudeau, has done so much good already and has saved so many lives, expends for each of its patient $1 per day. While in these two institutions patients with only incipient phthisis are admitted, at the Chestnut Hill (Philadelphia) Hospital for the Consumptive Poor, with Dr. J. Solis Cohen, the distinguished laryngologist, as visiting physician, and Dr. Bacon as house physician, consumptives are admitted even in the very advanced stages. Still this institution was able to obtain very satisfactory results indeed, as is shown by the latest report: Discharged as cured, 8 per cent.; improved, 11½ per cent.; unimproved, 6⅔ per cent.; died, 17⅓ per cent.; and the average daily expense was only between thirty and forty cents.

The value of isolation may best be shown by the work of St. Joseph Hospital for Consumptives of New York, where the most of the patients admitted are in the last stage of the disease. Dr. Cauldwell, the physician-in-chief, very kindly gave me the following information: This institution receives annually fifteen hundred consumptives, at an average daily expense of about fifty cents per patient. Dr. Cauldwell does not claim to be able to do more than care for them under existing circumstances, although a goodly number are discharged able to work again. But, leaving aside the curative results, St. Joseph Hospital, by taking care of fifteen hundred patients coming from among the poorest classes, suppresses annually fifteen hundred foci of infection. How many lives may not thus be saved indirectly?

Of course at Liberty, Saranac Lake, and Sharon, in view of the fact that these institutions are intended only for incipient cases, the curative results are

much more favorable. Thus Dr. Trudeau could report from thirty to thirty-five per cent. of cures with an average stay of eleven months ten days. This shows, as Dr. Trudeau well remarked in a recent letter to me, the very great importance of early diagnosis.

At the Liberty Sanatorium, of the patients who remained over three months in the institution fifty per cent. were improved, and about twenty-five per cent. cured. With those who stayed a shorter period the results were less favorable.

Dr. Vincent Y. Bowditch, of the Sharon Sanatorium, near Boston, reports twenty-five per cent. of "arrested cases" and a much larger percentage of improvements. Such results are remarkable indeed, considering that this latter institution is situated but a few miles from a large city and does not claim any special climatic advantages.

But aside from the considerable number of cures which can be effected in a sanatorium for consumptives, especially when the hygienic and dietetic treatment under constant medical supervision is strictly adhered to, there are other sanitary advantages of inestimable value which a community would derive from the creation of one or several sanatoriums for the consumptive poor. In a perfectly conducted sanatorium, where the curable cases are cured, and the hopeless cases cared for so that it is impossible for them to propagate the disease, all patients receive a hygienic education so that they may understand why they should expectorate only in a proper receptacle, why they should be careful with all other secretions, what they should do or not do to avoid new colds, why it would be unwise for them to marry as long as they are not perfectly cured, etc. When the patient who has passed through such a sanatorium returns to his home cured or only improved, he will become an educational factor in public hygiene. He will not only have learned to avoid the causes which may aggravate his condition, but he will still use his pocket spittoon and tell his friends that he uses it to protect them from any possibility of getting the disease through him, and at the same time he will know that through such precaution he also protects himself from reinfection.

By excluding all consumptive cases from our general hospitals and directing them to special institutions, we shall protect a patient with a pleurisy *a frigore* from the likelihood of developing a pleurisy of tuberculous nature. We shall protect the typhoid-fever patient, with his greatly reduced power of resistance, from becoming the prey of the bacillus of tuberculosis, which up to now has been an almost constant sojourner in our general hospitals, thanks to the lack of special establishments where patients afflicted with tuberculous diseases should have been cared for.

That there is never any danger from even the multiple creation of sanatoriums in the same locality, I have endeavored to demonstrate in several of my previous writings, by citing the statistics concerning the mortality from tuberculosis before and after the establishment of sanatoriums for consumptives in certain villages in Germany. These statistics were obtained from the official documents in these respective communities. In Goerbersdorf they cover a period of one hundred years; in Falkenstein a period of forty years.

Those desiring to read them in detail I must refer to my article in the New York MEDICAL RECORD of October 3, 1896, entitled "Are Sanatoriums for Consumptives a Danger to the Neighborhood?"

Here I can only summarize by saying that in these two villages, where five of the largest German sanatoriums are situated (Goerbersdorf and Falkenstein), the mortality from tuberculosis has actually decreased among the village people, being now one-third less than before the establishment of those institutions. This, no doubt, is due to the example set by the inmates of the sanatoriums, and it is also the best proof that well-conducted sanatoriums for consumptives are not centres of infection, but, on the contrary, places where one is safest from contagion. Still more, I venture to say that properly conducted sanatoriums for consumptives not only serve as hygienic educators of individuls, but as educators of communities as well.

From what has been said, it is evident that there can be no objection to the establishment of municipal sanatoriums or special hospitals for consumptives. The sanitary advantages derived therefrom for all communities, large or small, have been clearly demonstrated. It would remain only to show that through the multiple creation of such institutions the commonwealth would be the financial gainer as well, and that these establishments would not further the abuse of medical charity from which we all suffer at the present time.

When the worthy but poor consumptive is taken in time to an institution where his chances of recovery are still good, he will have little chance to infect the other members of the family, and he is likely to return, after a relatively short sojourn, restored to health and hygienically educated, ready to become again a breadwinner and supporter of his family. Now the maintenance of this patient in a municipal sanatorium for from three to six months or even longer, during the earlier stage of the disease, will cost the commonwealth no more than if he had been taken to the general hospital for perhaps the same period of time, but in a much farther advanced and more hopeless state of his disease. If the family were absolutely destitute the members would have to be supported by the municipality, whether the head of the family were in the sanatorium or general hospital. But since, when treated in time and in a special institution, he has twenty-five to thirty-five more chances of getting well, the likelihood of the community being obliged to support a widow and several orphans has thus also been reduced by nearly one-third.

Now let me develop to you a little ideal plan of how to proceed to select the proper cases for treatment in such institutions, how to avoid unnecessary expenditure on the part of city governments, and, lastly, how to avoid admitting to free treatment patients able to pay.

A large city desiring to treat its worthy consumptive poor must have a series of institutions.

(1) There should be a centrally located reception hospital.

(2) A city sanatorium, located in the outskirts and if possible in a somewhat elevated region, where the atmosphere is known to be pure. Here all patients should pass through a preparatory sojourn before being sent to the mountain sanatorium. The more advanced cases would all be retained here.

(3) A mountain sanatorium at no greater distance from the city than three or five hours by rail, at an altitude if possible of between one thousand and two thousand feet, on porous ground, with southern exposure, and as nearly as possible protected againt the coldest winds, preferably surrounded by a pine forest. To this place the selected incipient and the improved cases from the city sanatorium should be sent to complete their cure.

The central reception hospital receives all patients applying for admission or sent there by physicians or the sanitary inspectors. The patient is not sent to either the city or mountain sanatorium immediately after an examination. He has to remain in the reception hospital for a few days, to rest and receive some instructions as to his conduct in the city or mountain sanatorium. To lessen expense of the various institutions, he is expected to aid about the house wherever he may be and work as the doctor decrees. No one

else should have a voice in this matter. In the mean time proper inquiries are made, first of the patient's former physician, and then of the most reliable source, as to his financial standing. If the patient is able to pay something, he should not be refused admission, but this money should be used to help give the physician a salary for his service, to which he is as much entitled as the superintendent. For we must bear in mind that it is the constant medical supervision of the consumptive in a sanatorium which is the all-important factor in the hygienic and dietetic treatment. And I wish to state right here that I strongly disapprove of so-called homes for consumptives. These places are mostly always without a house physician, and as a consequence the hygienic and prophylactic measures are rarely carried out to the extent of making infection impossible.

The creation of municipal sanatoriums for consumptives requires a large staff of experienced physicians, who would have to devote a great deal of their time to such service. As I have demonstrated, the commonwealth would be the gainer thereby financially. It would be a great injustice should the physician alone be the loser.

The well-to-do or wealthy citizen can receive the hygienic and dietetic treatment in his private home or in a private institution. For the consumptive poor and those able to pay a moderate price, we need a large number of institutions under city-government control.

Our prophylactic measures, no matter how strict, will not suffice to do away with the centres of infection daily created anew in our tenement districts. To prevent the hopeless cases from communicating the disease to the large number of susceptible individuals with whom they will come in contact, to give the tuberculous patient yet in the early stages of the disease, but with little or no means, the best possible chance of becoming a well man and a useful citizen, we need municipal sanatoriums. Let physicians, statesmen, and philanthropists unite to further the creation of such institutions, for through them I think we shall not only alleviate much suffering, but may solve one of the most important and difficult problems in medical and social science.

TUBERCULOSIS—THE PINE BELT OF SOUTH ALABAMA VERSUS HIGH ALTITUDES.

By KIETH FONDE, M.D.,

Citronelle, Ala.

Is it not a fact that most physicians treating tuberculosis to-day are sending the vast majority of their patients to the high altitudes, without remembering the long list of contraindications? The fact that physicians of the mountains have furnished in this country almost all the literature on the subject of climatology is perhaps responsible for this. It is true, I think, that in any series of unselected cases a large majority would show positive contraindications to high altitudes. While I do not deny that high altitudes have a well-deserved place in therapeutics, it is only for a certain, or, I should say, one class of tuberculous patients. The writer believes, and proposes to offer some evidence to show, that sea air, if at sufficient elevation (three hundred to five hundred feet) and far enough inland (thirty to seventy-five miles, these figures being arbitrarily chosen), and preferably in a pine forest, with sandy soil and hills to insure perfect drainage, is far more beneficial to the majority of cases of tuberculosis than is the inland mountain air. As a type of such a location I select Citronelle, Ala., thirty-three miles north of Mobile, on the Mobile and Ohio Railroad, at an altitude of three hundred and sixty feet above the sea, the highest point within this distance of the coast between Boston and Galveston. Most parts of Florida are too low and moist; the deep sands make exercise unpleasant, and the glare and mosquitoes are disagreeable. Moreover, cottages are preferable to most of the hotels and large buildings. One patient then does not annoy others by coughing, etc. Patients are more separated, and the rooms of cottages are less likely to lack sunshine and ventilation than are those of large buildings. Citronelle, however, has the advantages of excellent waters, chalybeate and freestone from bold springs, and of being surrounded on all sides by high pine forests, and also of being easy of access from the north and east. A comparison of the available official reports, kindly furnished me by Dr. J. G. Michael, of Citronelle, observer of the United States weather bureau, shows that for each of the months of December, January, February, and March, from December, 1888, to March, 1894, inclusive, at Citronelle the minimum temperature averages fifteen degrees higher than at Asheville, N. C. The average maximum for the same period shows seven degrees warmer at Citronelle.

If we bear in mind that "chronic ulcerative phthisis includes the great majority of all cases of pulmonary tuberculosis, . . . and that a majority of all cases of pulmonary tuberculosis are combined infections," and the great importance of secondary infection, as emphasized by Prudden,[1] and that these cases are not suited to high altitudes, we shall use more discretion, prolong many lives, and gain a better record in the treatment of this disease. In Hayem's "Physical and Natural Therapeutics" (Paris), edited by Prof. H. A.

[1] New York Med. Jour., 1894, ii. Osler's "Practice of Medicine," 1896, 2d edition.

Hare, 1895, we find the many contraindications to high altitudes laid down by very high authority, and at the same time we learn something of sea air and coast climates[1] as follows: "The regularity in direction and time of the wind, the state of barometric pressure, the great intensity of the sunlight, the high proportion of ozone, the absence of dust, and the presence in the air of small particles of sodium chloride and traces of iodine and bromine. The physiological action of sea air has been investigated by a number of authoritities, especially by Beneke. It has been found to influence strongly the general nutrition, even in a more marked degree than sea baths. The surface of the body is cooled more quickly on the seacoast than in inland stations; the nutritive processes are active; the quantity of urine, the excretion of urea and of sulphuric acid are greatly increased, while that of phosphoric and uric acid is diminished. The body weight is also augmented. There is generally a fall in the number of respirations and pulsations; sleep improves, and the nervous system is slightly stimulated. The last effect may, however, be so marked that in impressionable persons it causes insomnia."

Let us see what further evidence there is at hand to support the proposition that the Southern coast climates do not obtain the medical patronage they deserve.

Dr. Solly, the able representative of the high-altitude advocates,[2] says: "Cold dry winds simply stimulate or else irritate the patient and hence improve relaxed catarrhal conditions, but make those which are inflammatory worse." On this point Hayem says: "A cold dry climate diminishes the cutaneous evaporation and increases the loss of heat; it predisposes to catarrhal, rheumatic, and renal affections." Dr. Solly proceeds: "Warm moist winds act as a tonic or increase irritability.[3] Apparently, humidity of the air, apart from other factors, does not in itself produce phthisis. The comparative immunity from consumption among the men of the British navy contrasted with those of the army, and the rarity of the disease in many islands, show this." Yet Dr. Solly collected a series of seven thousand seven hundred and ninety-five cases which he analyzed, and this led him to state that "an almost steady rise in the percentage of improvement toward the highlands" occurs. He says, however, of these cases: "It must, of course, be admitted that the material of which the cases are composed is too variable in quality to allow of any close comparison of results, but, as the number of cases and of reporters is so great, the law of average comes in to help us." And he closes the subject[4] by saying: "With regard to the elevation, high altitudes are of benefit to the majority of cases of phthisis, particularly those of a tuberculous type."

Ingals[5] says: "There is no climate to which consumptives may be sent indiscriminately, but suitable places should be selected for each patient. Some patients do better in cold weather, but the majority are better in summer. It will be found that those who feel best in winter are likely to be benefited by a comparatively cool climate, the others in a warm climate."

Without making further quotations I will venture the assertion that those subjects of pulmonary tuberculosis or chronic bronchitis, who are expectorating tough tenacious matter, especially those of irritable or of nervous temperament, will stand a far better chance of clearing their lungs of this infectious material in a climate virtually of pure sea air with its ozone and moisture. The latter, if not in excess, is more beneficial in these cases than the very dry atmosphere that tends to render the sputum more tough and tenacious, and more difficult to expectorate, the consequence being that many germs are retained that would be thrown off. The effect of moisture, I think, is demonstrated by the use of vapor inhalations under compressed air. Dr. Solly acknowledges the value of such inhalations:

"It is probable that the chief benefit is derived from the cleansing and stimulating of the bronchial tubes and from the deep-breathing exercises." This treatment, he continues, "should be carried out every day until the cough and expectoration become moderate." I believe it should be continued until there is no purulent expectoration, but Dr. Solly says: "It is probable that at sea level inhalations are more efficient when given in connection with treatment in the pneumatic cabinet."

In the treatment of secondary infections I prefer a McBride inhaler to the Globe. If the rubber tubing be made to fit closely, the vapor is inhaled under some pressure. A separate glass mouthpiece can be used for each patient, and these kept sterilized in separate glasses. The instrument can be thoroughly cleaned. If care is used in turning on air from the tank, a more or less perfect "aerial lavage"[1] is obtained, and I prefer a watery vapor like the following to balsamic vapor for most cases; the watery vapor liquefies the expectoration, so that coughing brings the matter up without great effort, and the lung is cleaned better: Carbolic acid, two to three per cent.; benzoate of sodium, five to ten per cent.; oil of eucalyptus or oil of cinnamon, one part to three or five hundred parts; glycerin, about ten per cent. In some cases lime water, fifty to seventy-five per cent., can be used instead of the benzoate. The decided alkaline reaction aids the solution of mucus, and the essential oils stimulate the glands of the bronchial membrane besides being measurably germicidal. This vapor is pleasant to inhale, and if the oils are alternated the patient does not tire of the taste. These drugs of course have been each used before, but, so far as I know, not in combination. Again, I think that in all incipient cases, and in those beginning to expectorate purulent matter, we should see that the tooth brush with an appropriate mouth wash is regularly used before each meal, for who can say how long a tuberculous focus may remain local?

In this way we may delay infection of the intestinal canal, for "in adults the lungs usually contain tubercle when it is present in the body (Louis' law)." A pure tuberculous infection, as a rule, is slow in its progress, and if those who come to you for their persistent cough, or after their first hemorrhage, were immediately removed from the impure atmosphere of a city (or from their trade) and their secondary infection, present in the vast majority of cases, carefully treated, you would prolong such lives and give them a far better opportunity of obtaining an arrest of the disease. You send such a patient more often to the cold dry atmosphere of the high altitude; he is usually restless, with rapid pulse and respiration, more or less fever, uncertain of rest after his arrival, and has an opiate cough mixture to help retain the germs he might otherwise throw off. I would suggest a different course, viz.: send him to an appropriately sedative climate, where he can go out almost every day of the year, and you have done the best. In selecting the point to which your patient shall go, the cold raw winds of the Atlantic coast region must not be lost sight of. It is for this reason that I have preferred the Pine Belt of Alabama.

LOOKOUT MOUNTAIN AS A HEALTH RESORT.

BY W. A. DETTRICH, M.D.

DURING the spring of 1888, while practising my profession in northern Indiana, it was my misfortune to contract pulmonary tuberculosis, for which I consulted the late Dr. Joseph P. Ross, of Chicago, and through his advice I sought a residence on Lookout Mountain. A full description of my case was published in the *Journal of the American Medical Association* of August 16, 1890, but suffice it to say that I have entirely recovered my health.

Lookout Mountain has been known in history ever since Hooker fought his famous "battle above the clouds," but further than this scarcely anything has ever been said of it, and little is known of it as a health resort by our Northern brethren. The mountain rises abruptly from the Tennessee River until it attains a height of seventeen hundred feet above the river, and twenty-two hundred and eighty feet above sea level. Lookout stands alone in its majestic beauty, being separated from all other mountain ranges by a wide and fertile valley. The top, or plateau, is an undulating surface, beginning at a point at its northern extremity and gradually widening out as it runs southward until it reaches a width of a mile or more. It extends across the line into Georgia, but it is only of that portion of the mountain lying within the borders of Tennessee that I shall speak, as it is the only part that is of easy access. The greater part of this plateau comes to an abrupt end, where the rock seems to have broken off precipitately and left a perpendicular bluff several hundred feet high. The soil is light and sandy, absorbing moisture so rapidly that within a few hours after a rain a person can go out walking without fear of getting damp feet. A large part of this plateau was cultivated previous to our civil war, but since then it has grown up in primitive forests of pine and oak, with the former predominating.

It is impossible to give a pen picture of this grand old mountain by which any effort of the imagination can form an idea as to its beauty and grandeur. To say the view from its top is grand would not express it. It is not only grand, magnificent, sublime, but also very entrancing. The scenery is varied from every point of observation, and to the lover of nature are presented views of which he will never weary, and this of itself will urge invalids on to keep out of doors and ramble from place to place. From its lofty summit seven different States can be seen, and with the city of Chattanooga lying at its base, with its fifty thousand souls, and ten different trunk railroads centring there, it affords a scene not to be found elsewhere. Its beauty can be appreciated only by the eye of the beholder.

Unfortunately the meteorological records (except its temperature) have never been taken until within the last year, but, comparing what we have with the observations taken in the city of Chattanooga, we can form a fairly good estimate. The mean annual temperature is 54° F., with a mean annual range of seventeen degrees. During the winter the temperature seldom falls below freezing, and only once during the past five years has it fallen as low as 2° F., and that last winter, while only fifty miles north of us it registered — 12° F. During the summer the temperature has risen above 88° F. only five times, and that occurred the past summer. The snowfall has been almost *nil*, with the exception of once last winter, when there was a fall of about nine inches. The average number of clear and fair days during the entire year is twenty-four in each month. It is impossible to give the rainfall, as no exact data have been kept of it. The average relative humidity can only be estimated, from that of Chattanooga. The United States weather observer there says it is at least 5 per cent. less than that of the city, and, as it is 71 per cent. in Chattanooga, that of the mountain must be 66 per cent. or less. The air is relieved of a great deal of its moisture as it is wafted across the mountain ranges surrounding Lookout on all sides, thus giving us a dry atmosphere. It is free from all micro-organisms and impurities, and there is nothing here to contaminate it. Sunshine is abundant, and gentle breezes are always blowing; sultry days and wind storms are unknown. The air is invigorating, it having neither the debilitating heat of the Southern clime nor the severe storms and cold of the Northern to affect us.

Dr. Wight, after a thorough investigation, states that consumption has never been known to occur among the natives of the mountain. Malaria seldom if ever occurs; at least I have never seen an original case of malaria or consumption during my five years' residence here; but, on the contrary, I have carefully watched the progress of a great many consumptives who came to Lookout with the hope of improving their health, and if possible receiving a cure. With very few exceptions, those who sought a residence here were either benefited or cured. The most of those who received no relief were so far advanced with their disease that it was utterly impossible for them to be benefited anywhere. Those with an acute affection naturally found the quickest relief, while those with the so-called fibroid phthisis improved slowly; but with proper care, diet, and exercise, every one (unless too far advanced) would find almost immediate relief, and if they remained long enough a cure would result in the great majority of cases. Consumptives, after visiting some of the other health resorts, such as California, Colorado, Texas, and Florida, and receiving no benefit, have come to grand old Lookout, and their improvement has soon became apparent. I recall, for instance, the case of a young gentleman, a professional brother, with phthisis, who had spent some time in Colorado and New Mexico seeking relief, but, failing to find it, had returned home, as he thought, to die. While at home he was advised by Dr. Ross to try this place. He did so, arriving here about January, 1889, and remaining until the following August, when he again returned home, to all outward appearances a healthy man, but still having a slight induration in the lung. He then went to California to practise his profession, but, after residing there a year or two, his trouble had increased so far that he died. I could cite numerous other cases like this: some patients remained long enough to receive a complete cure; others, after receiving a partial cure, would return home, thinking they could not remain away from business any longer. The one great trouble with consumptives going to a health resort is that they will not remain long enough; as soon as they are on the fair road to recovery they become anxious to return to their families, friends, and business. When invalids are sent away from home and relatives to seek a new clime, they should be instructed to remain (providing they improve) until their attending physicians say their health is entirely restored.

Other diseases that are benefited by a residence on Lookout are insomnia, nervous prostration, asthma, bronchitis, and the enteritis of infants. Children are frequently brought to the mountain during the summer months with cholera infantum, so sick that physicians say they could not possibly live more than a day or two in the city; yet, as if by magic, they commence to improve almost immediately after reaching its summit, and that with very little medicine. Only a few weeks ago Dr. Bowen, of Paris, Ky., brought his baby suffering from enteritis to the mountain, carrying it upon a pillow, and not thinking that it could pos-

sibly live. The child soon began to brighten up and feel better, and a few days ago they left the mountain with a healthy baby, and feeling very enthusiastic concerning the climate of this place.

Lookout Mountain is accessible by rail from every point of the compass. It has an incline and standard-gauge railway connecting it with Chattanooga, thus giving quick and easy access to that thriving city. Dr. J. A. Robinson, of Chicago, says: "The ideal requirement for the treatment of consumptives is a combination of all the requisites of a perfect climate, and also the opportunity to enjoy city life with its attendant evidences of civilization." He further says that the only locality where there is a possibility of such a combination is Lookout Mountain, Tenn.

It is an all-the-year climatic resort, and has the advantage over the other resorts in being within easy reach of all Northern and Eastern cities. The water supply is abundant, and as pure as can be found, consisting entirely of mountain spring water, either free-stone or chalybeate.

The facilities for entertaining invalids and tourists are now everything that could be desired by the most fastidious tastes.

SOME MISCONCEPTIONS OF NEW MEXICO CORRECTED.

By WILLIAM CURTISS BAILEY, A.M., M.D.,

FORMERLY INSTRUCTOR IN CLINICAL MEDICINE, [illegible]

The peculiar location of Las Vegas Hot Springs, and the conditions prevailing here, are not always clearly understood by the profession. Situated in the northern portion of New Mexico, it becomes a part of the tablelands of that territory. A study of its climate and general surroundings necessarily includes a study of the climate and topography of New Mexico, yet it has conditions distinctly its own.

Nestled in a little valley at the entrance of a cañon, which at this point is broadened, Las Vegas Hot Springs is surrounded four-fifths of a circuit by foothills of the Rockies, sufficiently high to protect it from severe winds and modify its temperature. It is watered by a brisk mountain stream of considerable volume, named the Gallinas River, which originates as a series of springs a few miles up a cañon of the same name. In the immediate vicinity of Las Vegas Hot Springs are thirty or more thermal springs, varying in temperature from warm to 144° F. An analysis shows that saline elements mainly predominate, although in some lithia is found, in others sulphur, in others iron, and in all free carbonic-acid gas exists in abundance. In the same field with the spring is located a natural peat bed, of no inconsiderable value as a medicinal agent. Las Vegas Hot Springs is six miles from any considerable centre of population. The hills and mountains encircling it are covered with trees and verdure, the principal trees being piñon, pine, and cedar. The soil, thus held down by roots of various kinds, is not readily disturbed by winds: hence no sandstorms occur at this place. Besides its location at the entrance of a cañon, Las Vegas Hot Springs is situated upon the northern slope of the Canadian Valley. This valley is protected on the west by the true range of the Rockies, which extend north and south through the centre of the territory. A spur of the Rockies, projecting at right angles from the main range along the New Mexico and Colorado line, marks the northern protection. These two ranges form a barrier against most storms arising in the Great Northwest, and modify the extremes of climate in the valley to a considerable degree.

The latitude of Las Vegas Hot Springs is an interesting one. It is the same as is found in the northern part of Africa and Arabia, portions of the world known to be the driest. Its longitude bisects that dry area which, beginning in the northern part of Texas, extends in a northerly direction through New Mexico and into Colorado. Instead of the extreme heat supposed to prevail in northern New Mexico, because of its southern latitude, it is a fact that the weather is decidedly cool and bracing during the summer months. Oppressive days are never known. This is explained by the height above sea level, the altitude being 6,767 feet. While the altitude modifies the extremes of summer, the protection afforded by the Rockies on the west and the eastern spur along the Colorado border on the north modifies equally well the extremes of winter.

A study of the great storm centres is essential to an appreciation of the difference between the area of great precipitation and the high tablelands of New Mexico. Such study is essential in order to understand why these high tablelands have attracted the attention of the profession as a refuge for people seeking health. Such study will convey a clearer idea than generally prevails of what is actually found upon observation.

In the eastern section of the United States the area of the greatest precipitation is found around the great lakes and certain portions of New England. The precipitation lessens somewhat as one approaches the Atlantic coast. It lessens to a greater degree and with considerable uniformity as one travels westward from the section above mentioned. After one has passed the Mississippi, the rainfall is found to decrease with rapidity, especially after that portion of the country is reached where there is considerable elevation above sea level. In eastern Kansas, for example, the annual rainfall is recorded as thirty inches; western Kansas, as twenty inches. Passing west from this State the elevation is noticeably rapid, and the annual rainfall is soon found to be only fifteen inches. When one has reached Las Vegas Hot Springs the annual precipitation is reduced to 12.7 inches. If one draw a line in a northerly and southerly direction along the western boundary of this great area of precipitation, which line shall represent a monthly rainfall of one inch or more, such line will be seen to vary in location and contour according to the month for which it is drawn. For example, in January it will be found on the average between longitude 95° and 100° W. All of that section of the United States east of this line, to the Atlantic coast inclusive, has an average monthly precipitation of from one to six inches or more. West of this line to the western slope of the Rockies, the monthly precipitation does not average one inch. In February the line has travelled a little west, on an average about two or three degrees. In March it has reached longitude 100° W. In April, in its northerly portion, it has covered Colorado, and has met with the Pacific storm centre: but New Mexico is still exempt, except in its northeastern corner. By June New Mexico is mainly covered. The precipitation in New Mexico from this time until September has considerably increased. The storm line now must be drawn along the western border of Arizona, and the average precipitation in New Mexico has become two or three inches. By September the storm line begins to recede. By October it has reached the eastern portion of New Mexico. By December it is nearly back to the eastern extremity. It is thus observed that while all portions of the United States east of longitude 97° W. have a continuous monthly average of more than one inch, New Mexico is exempt during this portion of the year. But while it is true that New Mexico is thus exempt, there is no month in which

some precipitation is not recorded; there is no month in which there are no stormy days; there is no month in which there is not danger from exposure. The advantage is found in the difference in amount of precipitation, which gives New Mexico a far greater number of days of sunshine per year, with a minimum number of stormy days, together with all the benefits which naturally follow from such excess of sunshine and such diminution of precipitation.

The directions not infrequently given by physicians to patients sent to this territory are something like this: "Go to the tablelands of New Mexico, where are dryness, altitude, and excess of sunshine. Select a home, on ranch or in town, where you may obtain wholesome food. Live out of doors all you can. Seek medical advice when required. Depend upon climate and exercise to restore you to health." This is wholesale advice prescribed in a wholesale way, with evident unfamiliarity with the general results accruing therefrom. Patients should be more carefully selected to whom such advice is given. The prescription should be more explicit, and warnings more frequent. It should not be expected that invalids whose constitution is impaired by disease; whose vitality is reduced below the normal; who are surrounded with home comforts and luxuries; who have been more or less under close medical supervision; who are, as a rule, unfamiliar with the favorable or unfavorable conditions affecting the disease which compels their absence; who, since they are invalids, are in no wise proper persons to direct their own case—can safely exchange home life for ranch life, to "rough it" as best they may.

It is interesting and instructive to pass through any of the trains bound west, especially during the winter months, and note the type of people seeking health, particularly those of a tuberculous character. It is not an infrequent occurrence that some of these fail to reach their destination alive. It is not unusual to find some so far advanced in the disease as to be unable to sit up during the journey. Others, less advanced, may walk about, but display evidences of streptococcus fever. Others, again, can scarcely be recognized among the well. If we follow these people from the train, and observe their attempts to regain health, we find that on an average fifty-three per cent. fail. Nearly all advanced to the third stage of the disease, that stage which Koch says has ceased to be tuberculosis, but is pus fever, die within a brief period after arrival here. Among those less advanced, imbued with the spirit of exercise, the result is fatal in a considerable proportion. It is an error to presume that patients unfitted to conduct their own case at home without medical supervision can do so in New Mexico. It is an error to presume that invalids who have made no special study of climatotherapy shall know how intelligently to obtain favorable results, because removed to a location possessing improved climatic conditions. It is an error to presume that any of nature's remedies are exempt from the generally recognized law that intelligence and experience shall direct their use. Whereas it is true that in the tablelands of New Mexico are found excess of sunshine, increased dryness, higher altitude, a minimum of precipitation, and less variation of temperature than in other sections of the continent, yet it is not all sunshine. There are cloudy and there are stormy days. There are days that have considerable wind. There are times when it is dangerous to expose one's self. There is an intelligent way to take advantage of the conditions prevalent here, and there is an erroneous way. There is, perhaps, no section possessing so great a union of nature's forces favoring restoration to health, yet caution must be exercised if proper advantage be taken of it.

MEXICO—ITS CLIMATE AND HEALTH RESORTS.

By H. S. SQUIRES, M.D.,

[illegible] Mexican Central Railway.

The ordinary observer, looking at a map of the republic of Mexico and noting that the tropic of Cancer passes almost through the centre, probably infers that the climate is warm in the winter and insufferably hot in the summer months. He does not know, or fails to consider, that the principal cities are located on a plateau which varies from thirty-five hundred to eight thousand feet in elevation, and that this elevation so modifies the climate that his inference is wrong in nearly every particular. The fact is that from the snow-capped mountains which overshadow Mexico City to either coast, every variety of climate is to be found.

But to the physician seeking a place for his patients and for tourists and invalids the climate of the plateau from El Paso, Tex., to Mexico City will be of particular interest. After the Rio Grande is passed, the first city of any importance and one whose climate may be taken as a type of the first and lower plateau, is Chihuahua. It is at an elevation of about forty-five hundred feet above the sea. Here the different seasons are more marked than they are farther south. The coldest months are from November to February, and during this season the cold is sufficient at night to make a grate fire comfortable, but during the day the air is bracing and warm enough to make it pleasant to sit out of doors without extra wraps.

The summer climate of Chihuahua is very agreeable, and often, when the heat is oppressive on leaving El Paso, one finds on his arrival at Chihuahua that, although he is two hundred and twenty-five miles farther south, the increase in altitude of one thousand feet can be appreciated by the cool bracing air. As one goes farther south from Chihuahua to Mapimi, Lerdo, and Torreon, the cold of the winter months grows less and the climate becomes more equable all the year until as he continues south he reaches Zacatecas, at an elevation of eight thousand feet, which place may be said to be the gateway to the higher plateau, whose elevation ranges from five to eight thousand feet, and on which are located the cities of Aguas-Calientes, San Luis Potosi, Leon, Lagos, Silao, Queretaro, Guadalajara, and Mexico City. And on this plateau the health and pleasure seeker finds the ideal climate, both winter and summer.

December and January are the coldest months. Even then the thermometer rarely reaches the freezing-point. Stoves are unnecessary, although all the new hotels are supplied with means of heating the rooms, as invalids sometimes find it chilly at night from the light air of this altitude. But the most delicate constitution would not need artificial heat after nine o'clock in the morning, for by that time the sun is well up, and the last particle of chilliness is out of the air. The days are delightful. The blue cloudless sky day after day becomes almost monotonous. Every day is clear and bright, and although one knows that at this season snow and cold are holding the greater part of the people of the United States within doors it is hard to realize it, for here the public gardens (and every Mexican town has two or three) and flowers are in bloom and the natives are practically living out of doors.

If possible the summer climate on this plateau is superior to that of the winter. As a rule the rains begin in June and continue until October. When one speaks of the rainy season it seems to convey to the uninitiated the idea of one continual rain storm day and night for months. Such is not the case, for it

rarely rains more than two hours a day and for the remainder of the day it is clear and cloudless.

A day in Mexico during the rainy season might be described like this: One is awakened in the morning by the sunshine pouring into his room. The birds in the patio of the hotel as well as those in the gardens are singing. The fragrance of the moist ground and flowers comes into the open window with the sunshine, and aside from the clear moist air one would not realize that it had rained the day before and that this was a morning in the height of the rainy season. It seems too beautiful to remain longer in the house, and one is soon up and out into the bright sunlight. The sky is cloudless except for a little bunch of clouds near the horizon, and as the day wears on this grows larger, until by three or four o'clock in the afternoon the sun is hidden and the rain commences. Shower follows shower for two or three hours, and then the clouds disappear, and by seven in the evening the streets are dry, the moon shines out, and then the population of the town comes to take a walk and sit on the plaza, and listen to the music. One can stay there until midnight if he chooses, without fear of cold or catarrh.

At this season of the year the vegetation is luxuriant. The fields are green, the trees are dense with foliage, and every bush that bears a flower is in full bloom. The heat even at midday during the summer months is not oppressive and the nights are always cool, so cool in fact that one must sleep under at least one blanket.

The monthly summary of the Meteorological Observatory in Mexico for July shows what the climate actually is:

TEMPERATURE OF THE AIR (FAHR.).

Monthly mean in shade	62.96 degrees.
" " " sun	93.14 "
Maximum in shade	77.18 "
" " sun	88.34 "
Minimum in shade	53.60 "
" " open air	46.40 "
Total range in shade	23.58 "
" " " open air	41.94 "

While the inhabitants of New York, Chicago, and other cities of the temperate zone are dying of heat stroke, this is July weather in Mexico City.

When this fact becomes impressed on the travelling public, Mexico must become one of the great summer resorts, as it is now a popular winter resort. Aside from the climate of Mexico there are certain hot springs which for ages have been looked upon as curative in certain diseases, and the experience of the past few years has demonstrated beyond a doubt that they have all the virtues which have been credited to them.

As one comes into the country from El Paso the first of these hot springs is located at Santa Rosalia, a town of about eight thousand inhabitants, three hundred and twenty-five miles south of El Paso. The town is a short distance from the railway station and the baths are about two miles back to the west of it. Coaches are at the station to meet all trains to carry passengers either to the town or baths, where the hotel accommodations are good. The waters at the springs are highly charged with sulphur, as the following analysis will show:

ANALYSIS OF SANTA ROSALIA SPRINGS.

	Grains in Imperial Gallon.
Chlorine	.2084
Sulphur, hydrogen sulphide	.0274
" hyposulphite	.0014
Sulphuric-acid anhydrite	11.5395
Carbonic acid	.7700
Oxide of sodium	.9401
" " potassium	.0399
" " magnesium	1.5524
" " calcium (lime)	5.1629
Chloride of potassium	.0644
" " sodium	.2961
Carbonate of sodium	1.3335
Sulphate of magnesium	4.6875
" " calcium	13.3238

The diseases most benefited by these waters are acute rheumatism, chronic arthritis, gout, specific blood diseases, and chronic malarial poisoning. In this latter very marked benefits have been derived. Those who have lived on the coast and who suffer from repeated attacks of malaria, even after having left the malarial district, find that after a two-weeks' course of baths the germs are entirely eliminated from the blood.

Aguas-Calientes, as its name implies (hot water), is one of the best-known resorts in Mexico. The city has between thirty and forty thousand inhabitants. The climate is fine all the year. The hotels are exceptionally good. The plaza and the garden of San Marcus are both beautiful. Horse cars run from the main plaza to the baths and to the river, about a mile in the opposite direction to the west, and to the big silver smelter, offering easy facilities for seeing the town and enjoying outdoor exercise. The hot baths are the great attraction, and are patronized by sick and well alike. The springs are east of the town, about a mile from the main plaza. Here the hot water bubbles up through the sand in the bottom of the bathing-tanks, supplying an abundance of clean water. Some of these tanks are roofed over, allowing the full amount of heat to be retained, while others are open and the water is cooler. The bath named San Ramon is the hottest, and is considered of superior quality to the others. Midway between the plaza and the springs are other bathhouses. The water supplying these baths is brought in solid masonry-covered ditches from the hot springs above, and the water is practically the same in all. In these one finds solid masonry tubs, shower baths, and a large swimming-tank.

The analysis of the water is: Temperature, 30° to 40° C.; without reaction to litmus, except the bath San Ramon, which is slightly acid and has a small amount of sulphur. The following table shows the amount of solids in grams to the litre:

Sulphide of sodium	.020
Sulphate of sodium	.030
" " calcium	.070
Carbonate of calcium	.030
Chloride of sodium	.018
Acetate of potassium	.005
Sulphate of magnesium	.008
Residue	.005

These waters are recommended for rheumatism, skin and nervous diseases. To the south from Aguas-Calientes the elevation of the plateau is lower and the cities of Lagos, Leon, Silao, and Queretaro are considerably warmer; they are all of interest and all have fine climates. Near Silao there are very fine sulphur springs, one four and the other twelve miles from the city. The water is very hot and highly charged with sulphur, and I judge that the analysis would show a great similarity to that of Santa Rosalia, although no analysis has been made that I am aware of. The same class of diseases which find relief at Santa Rosalia are also benefited by these waters.

The whole State of Jalisco is dotted over with hot springs, but those near Guadalajara are of principal interest. The city of Guadalajara is situated a half-day's ride from the main line of the Mexican Central Railway, at an elevation of five thousand feet. There are several lakes near the city, and the river into which Lake Chapala, the largest of these, empties passes but a few miles from the city. On this are the falls of Juanactlan, which, besides being a great natural curiosity, furnish power in abundance for the elec-

tric lights and water; the result is that Guadalajara is one of the best-lighted and cleanest cities in Mexico. The buildings are all fine and the gardens remarkably beautiful, and the climate is so modified by the proximity of the lakes that it is undoubtedly the finest in the republic. A short distance from Guadalajara is Chapala, which is the watering-place of Mexico. Here wealthy residents of Mexico City and Guadalajara have their summer home, where they can enjoy the close proximity of the lake. A new modern hotel is in course of construction, and when finished will afford increased inducements to pleasure or health seekers. Horses and boats can be rented for pleasure trips. Here are found hot sulphur and iron springs, the waters being used both for drinking and bathing.

Near Mexico City are the noted springs of Guadalupe and The Peñon. Quoting from a recent report of these: "In the city of Guadalupe Hidalgo, four kilometres north of the City of Mexico, exists the famous 'Well,' whose waters are taken for every class of disease and to which are attributed miraculous therapeutic qualities, not only from their composition but from the special virtues ceded to it by the Virgin of Guadalupe." The analysis of the water, as made by Prof. Leopold Rio de la Loza, is as follows:

Temperature	21.5° C.
Density	1.00134

Chemical Composition.

Air	8.73
Carbonic acid	234.90
Nitrogen	8.00
Total c.c. per litre	251.63

Solids.

Magnesia	.06540	Trace.
Organic matters	.02907	.15978
Bituminous matters	.02907	.01800
Total grams per litre	.60264	.72618
Total		1.32882

Near the well, which is used for drinking only, are baths which are fed by artesian springs and whose composition is similar to that of the well. Pilgrimages are made from all over the republic every year to these springs, and the cures reported are indeed marvellous.

About four kilometres northeast of Mexico City are The Peñon baths. From the time of the Aztecs these baths have been renowned. Illustrious men from all parts of the world have analyzed them and decided that they compare favorably with Kissingen, Wiesbaden, Wildbad, and Ems. Recently a hotel has been built with modern conveniences and bathhouses complete in every particular, so that parties now wishing to take advantage of these springs can do so with every comfort. The analyses of the different springs vary some in detail, but one is a fair type of all. The physical characteristics are boiling water with evolution of gas, without odor or color; to the taste, slightly sharp and salt; to the touch, slightly oily.

Temperature	46° C.

Having given a general idea of the climate and resorts of Mexico, I will close with a brief *résumé* of the diseases which are most benefited by a visit or residence here.

Patients with organic heart trouble and those who suffer from advanced pulmonary disease should under no circumstance come to Mexico.

Those with incipient phthisis may get some relief, and the locality best suited to them is on the lower plateau from Chihuahua south to Torreon, or at Guadalajara. Many who seem to be in good physical condition but in whom the bacillus tuberculosis has been demonstrated in the sputum, will get but little relief in this climate. The air is so rare that for the first few days they feel better. They are stimulated and feel that they have reached exactly the suitable climate; but after this first sensation wears off the action of the heart becomes affected with the increased work, the lungs become congested, and the patient fails rapidly. Many people who have a family history of consumption, but in whom as yet the disease has not developed, find that a residence here improves their general health and the tendency to the disease disappears.

Asthmatics as a rule find relief in this climate.

Sufferers from Bright's disease, uncomplicated with cardiac disease, are much improved. In these cases pulque has been tried quite extensively. It is a mild laxative and diuretic. Much has been said for and against its use. To gorge one's self with pulque, as many of the lower classes do, practically live on it, could not fail to bring about disease of the kidneys and liver, but a glass of pulque, taken two or three times a day, has proved to me beyond a doubt to be of great therapeutic value.

Many cases of nervous prostration and insomnia have been completely cured. The warm baths, the outdoor life, with a moderate amount of pulque at dinner and at bedtime, will quiet the nerves and bring on a natural refreshing sleep, devoid of all bad after-effects.

Physicians recommending patients to visit Mexico should bear in mind that the change from the sea level to an altitude of from five to eight thousand feet should be made as gradually as possible, and that for several days after the high altitude is reached exercise of a violent nature, long walks, or horseback riding should be deferred until the constitution has become accustomed to the change and the circulation becomes equalized under the new conditions.

The Medical Society of the County of New York has framed a bill against the abuse of medical charities.

Therapeutic Hints.

To Avoid Iodism in Giving Iodide of Potassium.—

℞ [illegible] ..... gr. ij
Ammon. ferrocitr. 1
Tr. nuc. vom. 8
Aq. anet ..... ʒ j
Tinct. cinch ..... m x
M. S. Teaspoonful in half a glass of water after meals.

—Stern.

Infantile Diarrhœa.—To make up for the liquid lost in purging, especially in the algid type, inject subcutaneously thirty cubic centimetres of the following, from three to six times daily:

℞ Sod. chl. ..... 7 gm.
Aq. dest. steril. ..... 1 litre.

Or Hayem's artificial serum:

℞ Sod. sulph. ..... 10 gm.
Sod. chlor. ..... 5 gm.
Aq. dest. steril. ..... 1 litre

—Lesage.

Reichmann's Disease.—Contrary to the opinion of Hayem that gastro-succorrhœa, or the presence of large quantities of fluid in the stomach during fasting, can be cured only by surgical treatment, Robin claims good results from purely medical measures.—*La Rev. Méd.*, May 26th.

When Quinine Cannot be Given by the Mouth it may be administered in suppositories in half-gram or gram doses.—J. Dunbar-Brunton.

In Bronchial Asthma.—

℞ Tr. opii croc. 5
Eth. sulph. 10
M. S. Gtt. l. every half-hour until the attack is quieted.

—Clymer.

Nephritic Colic.—

℞ Morph. hydrochl. ..... 0.20 cgm.
Atrop. sulph. neutr. ..... 0.05 cgm.
Aq. laurocerasi ..... 20 gm.
M. S. A Pravaz syringeful or one cubic centimetre containing a centigram gr. [illegible] of morphine.

This should be the maximum initial dose when the patient's susceptibility is not known.—Mabboux.

Coryza.—A generous pinch of the following mixture is to be snuffed into the nostrils at the very onset of symptoms and repeated five or six times at intervals of an hour. The powder must be freshly prepared.

℞ Pulv. ac. boric ..... 3 gm.
Menthol ..... 0.30 cgm.

—*Gaz. de Hôp*, June 29th.

Benzoate of Bismuth.—Benzoic acid, being twice as soluble and seven times as antiseptic as salicylic acid, being readily eliminated and non-caustic, should cause the benzoate of bismuth to be preferred to the salicylate.—Pierre Vigier.

In Soft Chancre, syphilitic ulceration, ulcerating lupus, intertrigo, etc., europhen gives excellent results and is preferable to iodoform on account of the odor.—Fournier.

Puerperal Fever.—Salt injections diminish the gravity of the situation, give hope to the patient and opportunity to the physician to seek other means of relief. When large injections are desirable:

℞ Sodii chloridi ..... 7 to 10 gm.
Aq. dest. ster. ..... 1 litre.

The injection can be made into regions rich in cellular tissue, such as the hips, buttocks, or lumbar region, or the solution can be injected directly into a vein.—Laskine.

Gastritis.—In the hyperpeptic form with abundant secretion without dilatation, prescribe a course of Carlsbad water unless there be heart disease or phthisis or the subject be feeble or aged. A formula for an artificial Carlsbad, for home use, is the following:

℞ Sod. sulph. ..... 2.5 to 5 gm.
Sod. bicarb. ..... 2 to 2.5 gm.
Sod. chlor. ..... 1 gm.
Aq. dest. ..... 1 litre.

Sterilize or consume while fresh.—M. G. Hayem.

Amenorrhœa.

℞ Pulv. cascarillæ ..... ää 1 gm.
Pulv. saffron ..... ää 1 gm.
Ferri redacti ..... 0.50 cgm.
Aloes pulv. ..... 0.30 cgm.
M. ft. chart. No. x. One or two in honey or preserves after the evening meal.

—Dauchez.

Gastro-Enteritis of Infants.—

℞ Benzo-naphthol 0.50
Bism. salicylat. 1

Divide into three packages, to be taken during the twenty-four hours on an empty stomach. Over one year of age, one gram of the first and a gram and a half of the second are advised.—Carrière.

Cardiopathy with Vascular Calcification.—In a study of the administration and elimination of the lime salts, Dr. Rumpf (Berlin Congress, June 12th) believes his studies have taught him: 1st. That if we furnish lime salts in abundance to the organism, the latter takes up a notable quantity. 2d. That in cases of calcification of the vessels the quantity of lime eliminated may be inferior to that which is introduced. 3d. That the blood contains a quantity of lime salts which varies according as the subject is normal or pathological.

Laxative in Hepatic Subjects.—

℞ Aloes [illegible] ..... 0.05 cgm.
Ext. rhei,
Ext. cascaræ,
Podophylli ..... ää 0.02 cgm.
Ext. hyoscyami,
Ext. bellad ..... ää 0.01 cgm.
S. For one pill to be taken at the beginning of the evening meal.

—Valentin.

Pulmonary Tuberculosis.—

℞ Strychninæ sulph. ..... gr. ss.
Atropinæ sulph. ..... gr. ¼
Cinchonidinæ sulph. ..... ʒ ij.
Ext. gentianæ ..... ʒ ss.
M. bene. Fiat massa et in pilulas No. lx. dividenda. S. One pill night and morning.

Or:

℞ Ferri et quininæ citratis ..... ʒ i.
Strychninæ sulphatis ..... gr. ½
Aquæ puræ ..... ʒ i.
Syr. acidi citrici ..... q.s. ad ʒ iv.
M. [illegible] S. [illegible] of water after meals.

—J. Hobart Egbert.

Tuberculosis with Syphilis of the Larynx.—In a report of fifty of the cases studied during the past year, the following clinical facts have been brought out: 1. Tuberculous and syphilitic ulcerations are found side by side in the larynx. 2. The presence of a syphilitic ulcer by the side of a tuberculous ulcer in the anatomy exercises a moderating influence upon the tuberculous deposit, if the syphilis be treated, and prolongs the life of the patient. 3. Do not rely upon the report of the microscope in all these cases, as the

tubercle bacilli will be found if there be a phthisis, but the syphilitic element, if present, may be overlooked. 4. In the case of a mixed sore, the syphilitic ulcer will generally progress more quickly than the tuberculous, but can be easily controlled if the right diagnosis is rendered.—E. HARRISON GRIFFIN, *Laryngoscope*, April.

Neuralgia.—

℞ Menthol,
Guaiacol ..... ää ʒ i.
Alcohol, absolute ..... ʒ xviij.
M. S. ʒ i. of this mixture to be rubbed lightly into the affected part two or three times a day.

—SABBATINI.

Uræmic Headache.—

℞ Potass. citrat ..... ʒ ij.
Spts. juniperi ..... ʒ vi.
Æther. nitr. ..... ʒ ij.
Inf. scoparii ..... ʒ vi.
M. S. A wineglassful t.i.d.

—DAY.

Epilepsy.—

℞ Ammon. bromid ..... ʒ vi.
Antipyrin ..... ʒ i.
Liq. potass. arsen ..... ʒ i.
Aq. menth. pip ..... ʒ vi.
M. S. ʒ ss. in water night and morning.

—WOOD.

Hysteria.—

℞ Acid. arsen ..... gr. ss.
Ferri sulph.,
Ext. sumbul ..... ää gr. xx.
Asafetidæ ..... gr. xl.
M. ft. pil. No. xx. S. One t.i.d. p.c.

—GOODELL.

Neuralgia.—

℞ Aconitinæ ..... gr. iv.
Veratrinæ ..... gr. xv.
Glycerini ..... ʒ ij.
Cerati ..... ʒ vi.
M. S. To be rubbed over the painful parts.

Do not apply to any abraded surface.—DA COSTA.

Or:

℞ Quininæ sulph ..... ʒ i.
Morphin. sulph.,
Acid. arsen ..... ää gr. iss.
Ext. aconiti ..... gr. xv.
Strych. sulph ..... gr. i.
M. ft. pil. No. xxx. S. One thrice daily.

—S. D. GROSS.

Diabetes Mellitus.—

℞ Sodii salicylat ..... ʒ iij.
Liq. potass. arsen ..... ʒ i.
Glycerini ..... ℥ i.
Aq. cinnamomi ..... ad ʒ iij.
M. S. ʒ i.–ʒ ss. t.i.d.

—J. C. WILSON.

Diabetes Insipidus.—

℞ Pulv. opii ..... gr. iv.
Acidi gallici ..... ʒ ij.
M. ft. chart. No. xii. S. One, three or four times daily.

—H. C. WOOD.

Tuberculous Meningitis.—

℞ Moschi ..... gr. iij.
Camphoræ ..... gr. xv.
Chloral. hydrat ..... gr. viiss.
Vitelli ovi ..... No. i.
Aq. dest ..... ʒ iv.
M. S. Wash out the rectum with simple enema and inject two ounces.

—SIMON.

Pleuritis.—In the acute stage:

℞ Potass. acetatis ..... gr. xv.
Tr. aconiti rad ..... gtt. ij.
Codeinæ sulph ..... gr. ½.
Spt. Mindereri ..... ʒ ij.
M. S. This mixture to be given every three hours.

When the pleuritis is of the rheumatic type, add ten grains of salicylate of sodium to the mixture given above. To get rid of an effusion of serum, withhold liquids as much as possible and give saline purgatives and diuretics; the blood being thus deprived of its watery elements will frequently take up the effusion from the pleura. If it does not do so, the aspirator should be used and from ten to twelve ounces of liquid withdrawn; the remainder will usually promptly disappear. The character of the fluid in the pleural sac may easily be determined by withdrawing some with a hypodermic syringe. When pus is found neither the aspirator nor the trocar and cannula should be used, but a free incision should be made in the seventh or eighth intercostal space on a line with the posterior axillary fold; the pus and fibrinous clots can thus be thoroughly evacuated, after which a drainage tube guarded with a safety pin should be introduced and a dressing of sterile gauze and cotton applied. The tube may be shortened from time to time, and when the discharge is thin or serous may be withdrawn. The initial operation as well as all subsequent dressings must be done with strict aseptic methods; the danger of acute infection is great. It is necessary to excise a portion of rib when drainage cannot properly be secured by thoracotomy. This allows thorough exploration, pockets of pus can be broken up, drainage will be perfect. Irrigation of the pleural sac I believe is harmful; it irritates and delicate adhesions are broken up.—E. H. JAMES.

Diphtheria.—

℞ Hydrarg. chlor. mit ..... gr. i.
Sodii bicarb ..... gr. xxiv.
Pulv. aromat ..... gr. vi.
M. ft. chart No. xii. S. One powder every two hours.

—STARR.

Or:

℞ Menthol ..... ʒ iiss.
Toluol ..... q.s. ad ʒ x.
Solve et adde:
Alcohol abs ..... ʒ ij.
Liq. ferri chloridi ..... ʒ i.
M. S. Apply with a cotton swab.

—LOEFFLER.

Gout.—

℞ Vini sem. colchici ..... ℥ ss.
Potass. iodidi ..... ʒ ij.
Liq. potass ..... ℥ iss.
Tr. zingiberis ..... ʒ ij.
M. S. ʒ i. twice daily in warm water.

—HODGSON.

Or:

℞ Lithii benzoat ..... ʒ ij.
Aq. cinnamomi ..... ℥ iiss.
M. S. ʒ i. in a wineglass of water every four hours.

—JACCOUD.

Chronic Bronchitis.—

℞ Apomorph. hydrochlor ..... gr. ss.
Syr. pruni virg ..... ℥ ij.
Syr. picis liquidæ ..... ʒ iv.
M. S. Tablespoonful three times a day.

—MURRELL.

Or:

℞ Acid. carbol ..... gr. xxv.
Tr. opii camph ..... ℥ iij.
M. S. A drachm added to one-half pint of hot water in the inhaler; use three times a day.

—N. S. DAVIS.

Typhoid Fever.—The whole question of the treatment of typhoid fever might be summed up as follows: Keep the bowels thoroughly open. Keep the alimentary canal as aseptic as possible. Give good nourishing food—that which the patient will readily assimilate. Give plenty of water by both the mouth and the rectum. Use the best intestinal antiseptic known. Never give opium. Never give phenacetin or acetanilid. Give strychnine as indicated. If this plan is followed you will rarely have a death from typhoid fever.—DR. MCCORMICK, *Journal of the American Medical Association*, July 10th.

Surgical Suggestions.

Sudden Death in the Puerperium.—1. Pulmonary embolism is the cause of death in most of these cases. 2. It is rare, but so shocks a community when it occurs that it is advisable to take every precaution to guard against it. 3. Phlebitis, varicose veins, prolonged labor, hemorrhage, anæmia, sepsis, cancer, syphilis, etc., predispose to its production. 4. In the presence of peripheral thrombosis, etc., absolute rest must be enjoined, especially between the second and third weeks of the puerperium, as this is the disintegrating period of the clots. The danger should also be explicitly pointed out to both patient and attendants, thus insuring to some extent a healthy co-operation. 5. The extreme changes in the blood usually ascribed to pregnancy and the puerperium are erroneous, and not corroborated by modern investigation. 6. Sudden death from air embolism in the puerperium is doubtful from physiological, pathological, and rational standpoints. 7. Shock is both a direct and indirect cause of death in the puerperium, and should be guarded against. 8. Organic heart affections, kidney trouble, etc., are capable of producing death at any time, and should not be overlooked in the puerperium. —Gallman.

Operative Treatment of Cancer of the Rectum.—In a very exhaustive paper on the operative treatment of cancer of the rectum, published in the *Annals of Surgery*, April number, Dr. Edward H. Taylor, of Dublin, summarizes his most important points as follows: 1. Great care should be exercised in the selection of cases for operation. Cancers which have exceeded the limits of the bowel and have acquired adhesions to neighboring parts do better if left alone. 2. The preparatory treatment deserves our utmost attention, having as its object the improvement of the patient's general condition, and as great a degree of intestinal asepsis as it is possible to obtain. 3. Free purgation, intestinal antiseptics, and rectal irrigation cannot have a really useful effect so long as there exists an ulcerating cancerous surface swarming with virulent micro-organisms. The use of the curette whenever possible, followed by irrigation, should accompany the other measures. 4. A preliminary colotomy can scarcely be recommended as a matter of routine. It appears to be chiefly indicated when attempts to empty the intestine and cleanse it have been either impossible or attended with difficulty. 5. We should consider a certain number of types of rectal cancer, both as regards their site and extent, with a view to determine the methods best suited for their removal. 6. Three cardinal rules may be suggested as applicable to all cases: (*a*) Control bleeding as much as possible. (*b*) Let the principles of aseptic surgery be as strictly observed as the field of operation will admit. (*c*) Avoid rough manipulations in the separation of the diseased tissues; let it be effected for the most part by a process of careful dissection. 7. The perineal operation is best employed for ano-rectal cancers; that is, for cancers which involve the sphincteric zone and extend for some distance above it. 8. If possible the rectum should not be split in its removal, nor should the finger be introduced to serve as a guide in its separation. Elastic ligatures should be applied and sterilized gauze placed beneath before it is cut. 9. Cancers situated in the suprasphincteric region are better removed by the sacral method. As contrasted with the perineal, it gives more room, bleeding is more easily controlled, separation of the disease is more readily effected, and it gives the best functional results. 10. Temporary sacral resection should not be entirely disregarded, owing to its manifest advantages over the more extensive mutilation of Kraske and Bardenheuer. 11. If, when the cancer is excised, it is found that the upper healthy segment descends easily, it is worth while making an attempt to suture it to the anal margin, having previously removed the mucous membrane from the lower segment. 12. In cases in which the ends of the bowel have been united after removal of the cancerous segment, it is well not to close the sacral wound completely, for fear of accidents. 13. For cancers situated high up, as well as for those of wide extent in the rectum, the formation of a sacral anus is often the only means at our disposal. 14. In such cases it appears advisable to follow the advice of Gersuny, and give the bowel a twist on its long axis before attaching it to the skin, the object being to establish a modified sphincteric apparatus. 15. The perineo-abdominal and sacro-abdominal operations are grave; they involve serious risks, and can be required only in very exceptional cases. However, we must encourage attempts which help to extend more widely the indications for complete removal of the disease and such as are suitable for those desperate cases in which the palliative treatment afforded by an artificial anus has hitherto been our only resource.

Intestinal Anastomosis.—Dr. T. Myles (*The Medical Press and Circular*, April 7, p. 350) draws attention to a fact that is too often lost sight of. The intestinal canal is a tube of living tissue, not merely a passive channel; its contents are propelled through it by muscular action, and it is not sufficient for us merely to be able to seal up an aperture in its wall. We want much more than this; we want to preserve or retain its normal peristaltic action, and to attain this object should be our ideal. Imagine what happens as the result of almost every method yet devised in an end-to-end anastomosis. The living contractile muscular wall at one spot is replaced by an inert cicatrix, in which the longitudinal muscular fibres end. Such cicatrix may be only a few lines in length or it may be more, but it exists, and exists as an obstruction, the contents of the bowel being forced through it by mechanical pressure from above, not, as it should be, by the contraction of its wall. Moreover, the expansile character of the gut is lost here also, the bowel at the seat of union cannot enlarge like the rest of the gut, and with a sudden constriction of the lumen and an inert area of bowel we have all the requisites for the production of an intussusception. Until we can restore the direct continuity of the muscular fibres (and this seems almost hopeless at present) we have not attained our ideal. Nevertheless, the more nearly we approach this condition—or, in other words, the smaller the cicatrix consistent with safety—the better and safer will be our results. It is for this reason I give my personal adhesion to the simple unaided suture in the great majority of cases. Whenever it is practicable, I believe it will give better results than any other method. But it is not always practicable.

Hypodermic Treatment of Syphilis.—

℞ Hydrarg. bichlorid.,
Ammon. chlorid. ..... āā ℈i.
Sod. chlorid. ..... gr. lxij.
Aquæ dest. ..... gr. xx.

Mix and filter. Add white of one egg dissolved in distilled water, ℥ivss. S. [illegible] superficially.

This is the equivalent of one-sixth grain of bichloride. Objections raised against this method are: Unnecessary pain, subcutaneous infiltration, large indurated and painful swelling, inflammation, abscesses, stomatitis, ptyalism, disturbances of circulation and respiration. The advantages claimed are: 1, Accuracy of dose; 2, exactness in intervals between doses; 3, rapidity of action of medicine; 4, small amount of mer-

cury and the short time needed to effect a cure; 5, the constant, never-ceasing effect of the mercury day and night; 6, the personal supervision of the physician; 7, the certainty of the patient's getting the right medicine, of its being properly administered at regular stated intervals, and of his inability to get your prescription refilled or to give your knowledge to a friend or sell it to some charlatan; 8, profit to the physician and economy to the patient on account of the saving of the drug bill of four years. The doctor with this method is sure of two very important things, his fee and his patient's gratitude for his speedy cure—quick delivery, so to speak; 9, absence of gastro-intestinal disturbances; 10, last, though not least, quick diagnosis in questionable cases.—Dr. Dabney, *New Orleans Medical and Surgical Journal*, April, 1897.

Erysipelas.—

℞ Tannin . . . . . 2 parts.
Camphor 5
Sulphuric ether 15

Paint the erysipelatous area every hour or two, proceeding from the healthy skin toward the centre of the patch. There is some burning at first, due to the evaporation of the ether. In a short time a crust forms, the swelling goes down, and in a few days the cure is complete.—*Gaz. degli Osped.*

When Shall We Use the Forceps?—1. The indication for the use of forceps rarely or never arises during the first stage of labor, before the membranes have been ruptured. 2. It may be necessary to employ the forceps during the first stage, when the waters have escaped on account of the increasing exhaustion of mother or child. 3. It is proper during the first stage of labor to apply the forceps for accidents, whenever they may arise, notably in certain cases of convulsions, placenta prævia, and prolapse of the cord. 4. In the second stage it is proper to apply the forceps one-half hour after the head ceases to advance, when there is no disproportion between the passage and passenger. 5. When, however, there is a tight fit between the child and the birth canal, the use of the forceps may be delayed. This delay should rarely exceed two hours after the head ceases to advance. 6. If the head is engaged, and neither advances with the pain nor recedes after the pain, the forceps should be applied promptly.—Dr. Park, *American Gynecological and Obstetrical Journal*, February, 1897.

Hydatid Cysts.—According to Australian writers, the aspiration of hydatid cysts is directly fatal in at least eighteen per cent. Of the rest, at least fifty per cent. are not cured. Owing to improvements in the methods of operation, the treatment by incision is most successful in all early and uncomplicated cases. Only a small wound is required, through which the parasitic cyst is most easily removed, and the thin-walled adventitous cyst falls together and is united without drainage whenever possible. The longer the hydatid cyst remains, the more adherent becomes the parasitic cyst and the thicker the wall of the adventitious cyst, so that the former is removed with difficulty, the latter does not collapse readily, and hence prolonged drainage is necessary with all its attendant troubles. The suppuration or rupture of the hydatid immediately puts the patient's life in grave danger. —Spencer, *The Hospital*, April 17th, p. 43.

Fatty Embolism.—Dr. Groube (*La Settimana Medica*, No. 22, 1896) concludes: 1. Though rare, cerebral fatty embolism may assume a dangerous grade, and should be considered in grave traumatism of the bones and soft parts. 2. The urine should be examined daily for three weeks for the presence of fat. 3. The quantity found in the urinary secretion will be a relative guide, inversely, as to the quantity circulating in the blood, for probably these two stand in inverse order. A slight quantity in the urine with increase of dyspnœa indicates a retention of fat in the blood and imminent danger. 4. The dyspnœa and lowering of temperature merit special attention. 5. Absolute rest of the injured part is necessary and rational; in complicated fractures change the dressings only when absolutely necessary. Massage is contraindicated. In contusions of the soft parts massage is allowable only later when the blood does not show a tendency to be absorbed. 6. Contusions often give rise to large cavities filled with fluid blood and fat. In these cases opening the cavity hastens healing and is devoid of danger. 7. If amputation be considered, the danger of fatty embolism should be kept in mind. 8. As to treatment, the kidneys and heart should be stimulated; for the latter digitalis being especially useful.

Diseases of the Gall Bladder and Bile Ducts.—Dr. A. W. Mayo Robson (*Medical Press and Circular*, April 7th), speaking on the above subject, said: "The presence of healthy bile in the peritoneum, such as might occur from an injury such as a stab, a bullet wound, or a blow, in a healthy individual may be tolerated for some time without serious damage, as in a case recorded by Thiersch, who successfully removed over forty pints of bile from the abdominal cavity after the gall bladder had been ruptured by a blow. The experiments of Schuppel and Bosbrom apparently prove that the peritoneum can absorb extravasated bile without serious trouble, and there have also been several cases reported in which extravasated bile has been successfully evacuated, either by tapping or by incision and drainage. Such a fortunate result cannot, however, always be looked for, as is shown by the specimens in some of the college and hospital museums. In all the cases in which the history is appended, the fact of the long survival after so serious an accident is at once borne home, and the lesson is manifest that operations would in each case have given good hopes of success. Mr. Lane has also published a case of rupture of the gall bladder in which the patient recovered after having a considerable amount of bile free in the peritoneal cavity for five weeks. This case confirms the views previously held, that when surgeons are dealing with the bile passages the entrance of a little bile into the peritoneum need not cause anxiety if only the bile be healthy."

Mustard as an Antiseptic.—One never goes into a house, or at least a locality, in which mustard cannot easily be procured, and my custom is thoroughly to rub and scrub my hands with a mixture of green or other soap, corn meal, and mustard flour, for about five minutes. After rubbing thoroughly into all the crevices and creases of the hands and nails by aid of a nailbrush, one may be absolutely certain that his hands are sterilized, no matter what he may have been doing previously. I have no hesitation in proceeding from an autopsy to the operating-room, if I may thus protect my hands. Used as indicated, the mustard leaves no unpleasant sensation; and one may feel that by the time it produces unpleasant tingling or rubefaction of the skin its essential oil has done its desired work as an antiseptic. I have discarded all other means of preparing the hands, and in several years' use of mustard in this way have never been disappointed or had the slightest reason to question its effectiveness. I might add also that it is an admirable deodorizing agent, and will take away from the hands all offensive odor of dead or dying tissues and all redolence of iodoform.—Dr. Roswell Park, *Buffalo Medical Journal*.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHERS:

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, November 27, 1897.

PHTHISIS AND RACIAL DETERIORATION.

THE theory of the relationship of phthisis to insanity is no new one, although now that most of the ills to which man is subject are put down to heredity, more notice is taken of the matter than formerly. Clouston observed, as long ago as 1863, the hereditary kinship of insanity and tuberculosis, as did also McKinnon and Van der Kolk. The belief that consumption is a form of neurosis is gaining ground and is held by many of those best able to speak with authority; at all events, it is on all sides conceded that persons of a neurotic tendency are much more liable to become infected with the phthisical taint than those who are in a state of sound bodily health. This question is now being regarded and discussed from every point of view. Mr. Lawrence Irwell, a member of the neo-Darwinian school of biology, has lately published in pamphlet form a paper on "Racial Deterioration and the Relation between Phthisis and Insanity," which he read at the meeting of the American Health Association in 1896. In this paper most of the up-to-date views in connection with consumption are set forth, and many of the most prominent experts on the subject are cited in support of the opinions expressed. The term diathesis is well defined as "an exaggerated temperament, signifying a proclivity toward some particular disorder." The first point touched upon is the risk attending the marriage of persons of phthisical tendencies. That this is a real and growing danger is a fact only too self-evident, and that there is need of much more caution than is at the present time observed in choosing a husband or wife from the physiological standpoint is as equally evident. But the spread of consumption is not the sole danger to be dreaded in such marriages. It has been proved that marriage into a family tainted with tuberculosis is often productive not only of phthisical but also of mentally deficient offspring. The blend of neurotic and tuberculous heredity appears to be specially harmful. Statistics collected in various parts of the world show that a phthisical family history is a preponderating factor in the etiology of idiocy and imbecility (being found in 28.31 per cent. of the cases tabulated by Shuttleworth and Beach). Naturally an increase of suicide moves hand in hand with an increase of insanity. It has been remarked that the farther a race advances in civilization, the more are its members given to self-destruction. In the history of the ancient world the suicidal mania was most rampant when civilization was at its acme. In Rome at one period suicide was almost an epidemic. Nations advance and deteriorate at one and the same time. Among the primitive races suicide is almost unknown. One of the saddest and most impressive signs of the time is the growing prevalence of self-destruction among the young. Child suicide is increasing both in this country and in most of the countries of the old world. Recently the number of youthful suicides in England alone has averaged over ten annually, and in America this average is very considerably higher.

In connection with suicide there are some curious points to be observed. One of these is that everywhere self-destruction is more common with men than with women. This may be explained partly by the fact that up to the present day woman has taken a less harassing share in the fight for existence, partly by the purer life which she usually leads, and partly by her natural repugnance to mutilation of the body. Another somewhat peculiar point is the time of the year in which the tendency to self-destruction is most marked. One would imagine that in the dreary months of winter and early spring, when all the surroundings are of a depressing character, to a person in an overstrung mental condition such a time would appear most fitting for ending life. However, this is not the case, and statistics demonstrate that suicides are most numerous in the months of May and June.

While allowing that heredity plays a very prominent part in disseminating the seeds of tuberculosis and insanity, it should not be forgotten that environment exerts no small degree of influence toward bringing about the same results. Unfavorable environment also tends to originate and call into activity latent forms of neurosis and produces mental as well as physical degeneracy. This truth is exemplified in the case of dwellers in the Alpine valleys, who have deteriorated from a stout and healthy race into cretins, both mentally and physically deficient. Therefore individuals predisposed by inheritance to neurosis should live amid bright and healthy surroundings and in as cheerful a mental atmosphere as possible. By these means the development of the taint may be kept in check. This treatment is, however, after all, but a palliative one, and it is argued that steps should be taken to strike at the root of the evil and endeavor to stamp it out. The only feasible remedy as yet suggested is that the question of marriage should be regarded in a much more serious light, and that parents should consult a physician before allowing their children to wed. Consumption is a matter of more than national—it is of universal import, and if any workable plan can be devised to eradicate its sources or even to lessen its dangers, such a plan should be adopted. Possibly in the course of time it will be found necessary in the interests of the health of the community at large to enforce laws restricting the reproduction of morbid taints. The time is not yet ripe, and until it arrives the only path to pursue is to educate the public in regard to the gravity of the situation.

THE EFFECT OF SMOKING ON THE HEALTH OF THE YOUNG.

In the *Journal of the Russian National Health Society* for September last, Dr. Mendelssohn contributes an account of the results of some observations made by him a few years ago, in regard to the effect of smoking on the health of students. In view of the great interest taken now by medical men in the question, these deductions should prove instructive. In 1890 a circular was sent to every student of the Army Medical Academy in St. Petersburg and in the Technological Institute, containing several questions which the students were asked to answer, and 1,071 replies were received. Among the medical students 54.66 were found to be habitual smokers, and among technological students only 47.18. Judging from these statistics, smoking appears to be very common among the young in Russia. Two began the habit at the extremely tender age of six, 3 at the age of nine, 11 at the age of ten, 5 at the age of eleven, 27 at the age of twelve, and so on, the maximum being reached at the age of seventeen. The average number of cigarettes smoked daily by a medical student was 19.64, and by a technological student 22.88. (The fact should be borne in mind that Russian cigarettes are very small.)

The tabulated figures relating to the effect of smoking on the health are very interesting, and if accurate go further to emphasize the fact that smoking is detrimental to the health of the young. Of the smokers 16.09 per cent. were found to have some affection of the respiratory tract, while only 10.69 of the non-smokers were thus affected. In respect to diseases of the alimentary tract, the figures were respectively 11.88 and 9.92 per cent.; and of both tracts combined, 8.77 and 3.22 per cent. Turning to the effect of the age at which the habit was begun, it was found that those who had acquired the habit before the age of sixteen years gave higher percentages of illness than those who began at or after that age. Another table illustrates the harmfulness of inhaling the smoke.

It has long been agreed that with the young smoking is not conducive to good health. To the ordinary adult it is probable that smoking in moderation is by no means hurtful; in fact, many distinguished medical men have held that to some persons it is even beneficial.

CONSUMPTION IN ITS RELATION TO THE WAGE-EARNING PERIOD OF LIFE.

The prevention of tuberculosis is a question of so surpassing an importance that any information bearing on the subject is always eagerly listened to. According to the vital statistics of the State of Massachusetts, the death rate in regard to the age of the victims to consumption has within recent years completely altered. Up to about fifteen years ago the highest death rate from tuberculosis was found among those between the ages of seventy and eighty. At the present time the highest death rate from consumption at any age is that which prevails at the age period twenty to thirty. The figures for the twenty-five years 1863–87 were: at the age period twenty-five to thirty—49.4 per 10,000 of the living at that age, and 62.1 of the living at the age seventy to eighty. This excess at advanced ages has disappeared in recent years. It would be interesting to learn whether the statistics from the various civilized countries of the world would afford the same results as those of Massachusetts. If so, the situation is indeed a serious one. Some comfort, however, can be extracted from the fact that not only in Massachusetts, but in America generally and in Europe, the death rate from consumption at all ages has decreased and is still decreasing.

THE DISCOVERER OF ANÆSTHESIA.

Once again the question as to who discovered anæsthesia has cropped up. It is not likely now that the disputed point will ever be really decided to the satisfaction of every one, although the mass of evidence would appear to be in favor of Morton's claim. In the last number of *The Johns Hopkins Hospital Bulletin* is published a portion of a paper read by Dr. Hugh Young, in support of the contention that Dr. Crawford Long was the true discoverer. Dr. Young certainly presents a strong case for Dr. Long, and provides some very interesting reading. It is explained that the reason why Dr. Long did not put his claims forward more energetically was on account of his modest and retiring disposition. The irony of fate was never more plainly exemplified than in the lives and deaths of the three claimants to the honor of the discovery which of all others was surely of the greatest benefit to mankind.

CLINICAL STUDY IN MOSCOW.

All the visitors to the International Congress in Moscow appear to have been greatly impressed by the facilities for pursuing clinical observation to be found in that city. The hospital there is said to be the most perfect in the world. It is situated at some distance from the town and consists of a dozen blocks, each one of which is devoted to a special branch of medicine or surgery. The erection of this building was partly due to private munificence. The government and municipality supplemented this gift with a grant.

THE ARTICLES ON HEALTH RESORTS.

The articles on health resorts printed semi-annually in this journal make no pretension to completeness; they are suggestive only, and are intended simply as pointers for physicians who may need hints in this direction for their own use or for the use of their patients. That these articles have been appreciated has been amply demonstrated to us, since they were begun in June, 1896, by the very numerous communications we have received from members of the profession in all parts of the country requesting further information. The transportation department of the

MEDICAL RECORD, inaugurated at the same time, has been the means of aiding hundreds of physicians since that time in carrying out their plans for travel and sojourn. Circulars, booklets, and timetables of all lines and places are on application sent without charge to any subscriber to the MEDICAL RECORD.

News of the Week.

One Way to Prevent the Abuse of Medical Charity.—The New York Cancer Hospital (One Hundred and Sixth Street and Central Park, West) will hereafter send the following notice to the physician of every patient who applies for treatment at that institution:

"NEW YORK CANCER HOSPITAL,
"106th Street and Central Park, West.

".....189

"..... M.D.

"DEAR DOCTOR: M.....
has applied to enter this hospital. We understand that.....has recently been under your care; kindly let us know if you consider.....
a proper case for free medical treatment.

"An answer will oblige,

"Yours very truly,

"_____

"*Superintendent.*"

This is an example worthily set for every other hospital in this or any other city.

Society for Medical Progress.—The following officers were elected for the ensuing year: *President*, Dr. Louis Fischer; *First Vice-President*, Dr. M. T. Sime; *Second Vice-President*, Dr. Thomas Buckley; *Treasurer*, Dr. Harold Lesser; *Secretary*, Dr. F. P. Lowenstein.

Bayonne Hospital, N. J.—Dr. Charles W. Allen has been appointed consulting dermatologist to the above institution.

Dr. Martin Roche, president of the Pennsylvania College of Pharmacy and of the Polytechnic University, died at Philadelphia on November 15th, in consequence of an apoplectic attack, at the age of seventy-one years. He began the study of medicine at the naval hospital in Portsmouth, Va., and was graduated from the medical department of the University of Pennsylvania in 1852.

Northern Medical Association of Philadelphia.—A stated meeting of the Northern Medical Association was held on November 12th. An informal discussion was held on the subject of "The Ethical Standard of Membership in the Northern Medical Association," in the course of which reference was made to the participation by members in benefit and other public associations. Dr. I. P. Stritmatter presented a number of specimens, illustrative of the treatment of endometritis by means of irrigation with solutions of mercuric chloride and the employment of the stem pessary. Dr. Samuel Wolfe read a paper entitled "Physiological and Pathological Observations Connected with Disease and Injury of the Cervical Cord," relating two cases in which death resulted from fracture of cervical vertebræ.

Health Protective Hospital for Contagious Diseases in Philadelphia.—The agitation that has been going on in Philadelphia for the last three years has finally culminated in the purchase of a site for a pay hospital for the treatment of contagious diseases, in contiguity with the Municipal Hospital. A considerable sum of money has already been collected, and a corporation, including representatives of the Women's Health Protective Association and the Philadelphia County Medical Society, formed, which held its first meeting on November 15th. The object of the new institution is to furnish accommodation for those attacked with contagious diseases in boarding-houses, hotels, or apartment houses, or in their own homes, and who will desire some such means of isolation, for which they will be glad to pay.

Dr. C. B. Meding, of this city, has been elected executive surgeon of the Harlem Eye, Ear, and Throat Infirmary, in place of Dr. R. E. Swinburne, deceased.

"The American Practitioner and News," of Louisville, will be changed at the beginning of the year from a biweekly to a semimonthly.

The Spitting-Nuisance in Germany.—The spitting-nuisance, which in Germany is almost as bad as in our own land, has begun to receive attention from medical men. At a recent meeting of the German Public Health Association there was a discussion on the spread of infectious diseases at health resorts and on railways, and it was generally agreed that one of the most effective means of spreading disease was the habit of promiscuous expectoration on the floors of railway carriages and in public streets. Professor Esmarch recommended that the government be requested to forbid the practice.

American Dentists in Italy.—The Italian government has apparently had enough of tourists, for it is doing its best to keep them away by its crusade against non-Italian physicians and dentists. Recently, according to the Rome correspondent of *The Lancet*, a circular has been addressed by the minister of the interior to the prefects throughout the kingdom. It is neither more nor less than a mandate charging these functionaries to invite all non-Italian dentists to furnish proof that in addition to their home qualifications they possess one from a recognized qualifying body in Italy, failing which these gentlemen are to be held as practising illegally, are therefore to be called upon to desist from practice, and in the event of their being contumacious to be denounced to the judiciary authority.

Vaccination against Typhoid Fever.—The experiments recently made at Maidstone in antityphoid inoculation were unsatisfactory, as they were begun at a time when the epidemic was waning. Now Professor Wright, of Netley, proposes, with the permission of the military authorities, to inoculate all the British

troops, especially those sent to India, in order to render them immune to the typhoid fever which always prevails there to such an alarming extent.

The Tri-State Medical Association.—The annual meeting of this society was postponed by reason of the yellow fever, to Wednesday and Thursday, December 15th and 16th. The meeting will be held in Memphis.

Dr. John N. Mackenzie, of Baltimore, has resigned the chair of laryngology in the University of Maryland.

Typewritten Prescriptions.—Mr. Labouchere proposes, in *Truth*, that a law be passed making it obligatory to typewrite all prescriptions, so that they may be filled with safety and accuracy. He says that he is led to make this suggestion by the confession of a druggist, who said that he always did the best he could with an illegible prescription, and when he could not read it at all put up what he thought best.

A Ruling on a Question of Ethics.—At a recent meeting of the Medical Society of Santa Clara County (Cal.) a resolution was adopted to the effect that the code of ethics does not preclude the members of the society "from freely rendering most prompt and efficient assistance to the sick, the injured, or the suffering, and obtaining the history of such cases from all available sources, whether previously attended by homœopathic or eclectic practitioners, or unlicensed fraudulent pretenders—the right to change physicians being unquestionable; or from receiving in emergencies needed assistance and advice from persons, whatever their titles or pretensions; nor do such codes of ethics preclude regular physicians from seeing or visiting the sick or injured while attended by homœopaths or eclectics or unlicensed persons, and freely stating their opinions about diagnosis and treatment, and doing all else required by humanity and friendship; but they do preclude their representing or regarding such visits and attendance as professional consultations or agreements, or personally receiving professional pay therefor, as lowering the character and standing of the medical profession and misleading the sick and their friends and the community."

Dr. Howard A. Kelly.—A reception was tendered to Dr. Howard A. Kelly, of the Johns Hopkins University, Baltimore, by the Medical Club of Philadelphia in the parlors of The Aldine one evening last week.

Insuring Students against Mishap.—An arrangement has been made by the authorities of Heidelberg University with an accident insurance company, whereby a student who may be disabled by an accident in the chemical and physical laboratories receives $500, or a proportionate sum if the accident causes temporary disability only.

A Cystoscopic Controversy. — Drs. Casper and Nitze quarrelled so long and so loud over the question of priority in the invention of a cystoscope, which the former had exhibited as of his own devising, that they finally appealed to the law. Many of the prominent surgeons of Berlin were called as experts, and differed as widely in their sworn testimony as if they were expert witnesses in a murder case. Finally Casper won the suit, and Nitze was adjudged to have no well-founded claim to priority. He not only lost his case, but had to pay a fine for saying what was not.

Dr. Guiteras, who was sent to Texas by the Marine Hospital service to investigate certain cases of supposed yellow fever, has been the object of much intemperate abuse by certain medical men in that State because he diagnosed the cases as yellow fever.

The Temerity of Old Age.—A man aged one hundred years and one month was married in St. Joseph, Mo., on November 18th, to a widow aged seventy-seven years. Both bride and groom are said to have been in excellent health up to that time.

Suicide of a Physician.—A medical practitioner in Birkenhead, England, was recently sentenced in a Liverpool police court to two months' imprisonment for neglecting to comply with a maintenance order obtained by his wife. Before the judge had finished speaking the man swallowed an ounce of hydrocyanic acid with a promptly fatal result.

Football in Georgia.—The Georgia senate passed the anti-football bill on November 18th by a vote of thirty-one to four. The prohibitive bill had already passed the house by a vote of ninety-six to two. It is currently believed that the governor is opposed to the bill, but his veto would be ineffective against such numbers. The bill prohibits the playing of a game of football in any place in the State where admission is charged.

Perils from Electricity.—A man was killed in Philadelphia last week by a shock of electricity while he was looking in a shop window. It was raining and he was holding an umbrella with a steel rod in it over his head. Above him was an electric arc light. The end of the umbrella rod touched the iron frame of the lamp and a current of electricity passed through his body to the iron covering of a coal shaft in the sidewalk, killing him instantly. A man was killed in a similar way on Eighth Avenue in this city about three years ago.

Alleged Spread of Diphtheria by Means of Pencils.—An inquiry has just been concluded in Indianapolis concerning an unusual increase in diphtheria among public-school children since the opening of the fall session. As a result of this inquiry the sanitary authorities have concluded that the disease has spread through the distribution of lead pencils and penholders. Under the system in vogue in the schools each child is required to take its pencil and penholder to the teacher's desk in the afternoon. These are placed in a box, and the next day are redistributed. It is proposed to sterilize the pencils hereafter previous to their distribution each morning.

Repressing Flirtation.—A telegram from Louisville to the daily papers says that it has been found

necessary to place two policemen on guard before the Louisville School of Medicine every day at the time the girls' high school is dismissed, in order to prevent the medical students from flirting with the young women of the high school, which adjoins the medical college. The students deny that they have ever so much as glanced at the high-school girls, and say that the charge was brought merely to induce the city authorities to build a new schoolhouse in another locality.

The Lane Lectures.—The announcement is made that the third course of Lane lectures before the students of Cooper Medical College of San Francisco will be delivered by Dr. T. Clifford Allbutt, of Cambridge, England. The subject of the course will be the diseases of the heart.

Damages for Injuries Resulting in Death.—About two years ago a constitutional amendment was passed in this State, providing that the amount of damages recoverable for injuries (railway or other) resulting in death should not be subject to any statutory limitation. It was formerly limited to $5,000. One of the results of this amendment was seen recently in a verdict of $30,000 damages against the New York, New Haven, and Hartford Railroad Company for injuries which resulted in the death of Dr. Mixsell.

Police Surgeoncies in Brooklyn.—Two hundred and seven medical men, young and old, veterans and recent graduates, came up for examination last week for appointment on the board of police surgeons. The salary of a police surgeon will be $3,000 a year. There will be two hundred and three disappointed ones, as there were but four vacancies to be filled.

Objections to the Providence Hospital.—A resident of Washington has brought suit in the district court for an injunction to restrain Treasurer Roberts from paying any money to the Providence Hospital, upon an agreement between the surgeon-general of the army and the directors of the hospital. This agreement provided for the support and medical treatment of ninety-five medical and surgical patients who are destitute. There is also another agreement between the district commissioners and the directors of the hospital, wherein it is provided that the commissioners "will erect on the grounds of the hospital an isolated building or ward for the treatment of minor contagious diseases." The petitioner alleges that the hospital is a Catholic institution, that the contract referred to is unauthorized by law, and that the appropriation of funds of the United States for the use and support of religious societies is unconstitutional.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending November 20, 1897. November 17th.—Surgeon C. G. Herndon detached from the bureau of medicine and surgery and placed on waiting orders; Assistant Surgeon J. C. Thompson detached from the naval laboratory, Brooklyn, and ordered to the naval hospital, Mare Island, Cal.; Assistant Surgeon W. B. Grove detached from the naval hospital, Mare Island, Cal., on reporting of relief, and ordered to the *Oregon*. November 19th.—Passed Assistant Surgeon T. B. Bailey detached from the *Yorktown* and ordered home with two months' leave.

Work of the Food Inspectors.—During the past summer the food inspectors of the New York board of health seized and destroyed 2,578,448 pounds of fruit, meat, fish, and other food stuffs. Of these there were 1,012,145 pounds of bananas, 39,905 pounds of apples, 2,120 pounds of eggs, 320,105 pounds of watermelons, 50 pounds of onions, 275,285 pounds of fish, 437,850 pounds of meat, 7,730 pounds of cucumbers, and 1,850 pounds of pickles.

No More Forced Charity for Private Institutions.—The board of estimate has been informed by Corporation Counsel Scott that chapter 754 of the laws of 1895 rendered discretionary all mandatory laws, passed prior to that time, compelling the board to insert certain estimates in the annual budget to provide money for private charitable, correctional, and reformatory institutions. Hitherto these institutions have demanded certain sums as a matter of right under the provisions of these laws. The corporation counsel says that the board of estimate may now consider the applications for relief from the institutions on their merits, and appropriate such sums as in its judgment it deems just. Comptroller Fitch was directed to notify the heads of the institutions interested of the opinion of the corporation counsel, and advise them that they must press their claims on their merits upon the consideration of the final estimates. The aggregate amount which the city has been compelled to raise annually by these mandatory laws has been in the neighborhood of $1,000,000. A committee has been appointed from the County Medical Society to look after the matter.

The Health Board and the County Society.—"It may well be asked by what right in law or equity does the health department or its physicians presume to treat disease in public institutions or elsewhere, and in some instances attempt to dictate or to discredit the diagnosis of the condition or the treatment of patients under the care of a licensed practitioner, not only in private life, but in public institutions also. If the afflicted persons are poor and in need of hospital care, they should be treated like other poor patients, by the physicians of the various public institutions under the care of the commissioners of charities. If they are well-to-do, then they should be treated at home by the private practitioner, or in a secluded public or private hospital if need be, and pay for the services rendered."—*Dr. A. M. Jacobus, in Annual Address before the Society.*

Election of Officers of the Woman's Hospital Society.—The following officers have been elected by the Woman's Hospital Society to serve for the ensuing year: *President*, Dr. Paul F. Mundé; *Vice-President*, Dr. Leroy Broun; *Secretary and Treasurer*, Dr. James N. West; *Executive Committee*, Drs. Nathan C. Bozeman, E. L. H. McGinnis, J. Dougal Bissel, and George H. Mallett.

Clinical Department.

SERUM IN TUBERCULOSIS.

By CHARLES C. BROWNING, M.D.,

A BRIEF report of cases treated by me with tubercle antitoxin is submitted. Since May, 1895, I have treated ten patients, with the following results, to wit: two deaths, four recoveries, and four under treatment.

The two who died commenced treatment when the disease was far advanced, but obtained so much relief from the distressing symptoms incident to this stage of the disease that the treatment was continued to the end. When the serum was discontinued for a short time, these symptoms returned, to be relieved when the serum was resumed.

Of the four patients reported cured, all are still under observation. Three are adults, and were suffering from pulmonary tuberculosis in the second stage. There have been no symptoms of the disease for periods varying from eighteen months to two years, the time since treatment was discontinued in the several cases. The fourth case was that of a child, five years of age, who had suffered from Pott's disease of the spine and was suffering at the time of the beginning of treatment with hip-joint disease. The serum was administered for four months, per rectum, with results which were alike surprising and satisfactory. There is no indication of a return, although six months have elapsed.

Of the four patients under treatment, all have improved. Two are far advanced and will probably obtain only temporary relief. The other two are progressing rapidly, with good prospect for final recovery. One of the latter is taking the serum per rectum.

The diagnosis in all these cases was verified by the microscope.

REPORT OF OPERATIONS IN THREE CASES OF UMBILICAL HERNIA IN ELDERLY WOMEN.

BY PATRICK CASSIDY, M.D.,

[illegible] SURGEON [illegible] W. W. [illegible] HOSPITAL, NORWICH, CONN.

IN comparison with the number of operations for inguinal and femoral herniæ, the reported operations upon umbilical herniæ are small in number; in fact, surprisingly small. This rarity of such operations is not in all probability due to the great comparative rarity of umbilical hernia, but to the fact that in a majority of cases trusses and other appliances act very well in keeping back the hernial contents. On this account the individual is not troubled by the hernia; therefore the surgeon is not called upon for interference. To tell the truth, a great many persons having herniæ which give them at times great trouble do not even then consult a surgeon, but prefer to hurry to the instrument maker and have a truss fitted. Of course, in cases of enormous hernia or strangulation, the surgeon is consulted and operation is often advised. The three cases to be reported bear out my statements. In one of these cases the hernia had been of only one year's standing, but in the other two cases several years had elapsed since the beginning of the trouble. These cases also testify as to the rarity of this form of hernia, for they are the only cases of umbilical hernia which have been operated upon in this hospital during its four years of existence.

CASE I.—Mrs. G——, aged sixty-three, is a farmer's wife, living in Ledyard. For twenty years she had an umbilical hernia. During these years she had worn trusses of various forms with poor results. Yet, in spite of the fact of hernia, she had borne eight children. She reported that the hernia had been "strangulated" twice, and for two weeks before coming to the hospital she had suffered almost intolerable pain and much inconvenience otherwise. On account of this great pain she decided to come to the hospital. Upon examination the ring was found to be about one inch in diameter and the abdominal walls were very lax. She was operated upon May 17, 1897. After the sac had been exposed, it was opened and was found to be filled with omentum. This was ligated and cut off. The sac, being adherent everywhere to the ring, was cut off at a short distance, about 0.5 cm., from the ring. The ring was closed by a row of chromicized catgut sutures in such a way as to bring the serous surfaces of the sac together. The bellies of the rectus were dissected for, and after being found were brought together with the fascia in apposition above the ring and stitched with the gut sutures. Next the skin incision was closed with interrupted silk sutures. The patient made an uninterrupted recovery, the wound healing by first intention. She has been, since her discharge, attending to her duties as housewife on a farm.

CASE II.—Mrs. McB——, aged forty-nine, residing in Wauregan, has had several children. During the past five years she has had an umbilical hernia. This had never given her any trouble until May 17, 1897, four days before coming to the hospital. On this day, after a fit of coughing, the tumor became much enlarged and caused pain. There was vomiting but no constipation. She was admitted to the hospital, May 21, 1897. On examination an irreducible hernia was found at the umbilicus. The percussion note was dull over the tumor. It was decided to operate. At operation, after cutting down on the sac, this was found to be adherent to the ring and was cut away at a short distance from the ring. The contents of the sac consisted chiefly of omentum, but there was also included a portion of intestine, making a partial enterocele. A large portion of the omentum was ligated and cut off, and the residue of the hernial contents was returned to the abdomen. The wound was closed in the manner described. A rapid recovery followed, the wound healing by first intention.

CASE III.—Mrs. W——, aged sixty, resides in Norwich. She had been troubled by an umbilical hernia for about a year. Occasionally, she said, it would become "strangulated." On these occasions she got relief by assuming a recumbent position and applying heat to the tumor. It would at times diminish in size, but never disappeared. On the evening of March 23, 1897, she was taken with a severe attack of vomiting, coincident with which the tumor became full, hard, and painful to the touch. Dr. L. S. Paddock was called in. He attempted taxis, but failed to reduce and had her removed to the hospital at once. She arrived there at 4 A.M., and sodium bromide was given and ice applications were tried. She had no pyrexia. At the operation an incision was made in the middle line, over what appeared from percussion to be omentum. The sac, after it was opened, was found to be chiefly filled with omentum, which was adherent to the abdominal walls. After dissecting through this, several knuckles of congested and gangrenous-looking colon were found. The ring, which was tense and constricted, was enlarged by incision. This enlargement was followed by recovery of circulation in the greater part of the intestine and the disappearance of the œdema of the whole mass. The tenseness was also relieved. The incision was now enlarged and the sac opened in all directions. The sac was cut off as in the other two operations. The intestines were washed in saline solution and then returned to the abdominal cavity. The sutures inclosing the incision were made as in the

other operations, but in this case a gauze drain was introduced. The patient rallied nicely from the anæsthetic, but the pulse was very weak. Stimulants were freely administered, but her condition grew gradually worse and she died at 4 A.M. of the morning after. At the necropsy the small intestine was found to be filled with blood from internal oozing. During the last few hours of life several ounces of blood were passed per rectum.

Of course, too short a time has elapsed since operation in Cases I. and II. to give good grounds for claiming a cure, but up to the present the patients have been able to attend to their duties, which are by no means light, without any recurrence and with no discomfort.

ONE-SIDED SPASTIC SPINAL PARALYSIS (PRIMARY LATERAL SCLEROSIS).

By HAROLD N. MOYER, M.D.,

CHICAGO.

It is hardly necessary to discuss the question as to whether there can be a primary lateral sclerosis. Some authors, notably Oppenheim, are of the opinion that it may occur, while Dana discards the term altogether. Our recent acquisitions regarding the neuron have altered our conception of the system diseases of the cord and their relation to the brain. Regarding the nerve cell and fibres as practically the same structure in a pathological sense, there can, I think, be little doubt that motor fibres may degenerate at the beginning in the cortex, or the degeneration may have its beginning at any point along the course of the fibres. Without doubt there are well-marked cases that can be explained by no other hypothesis than that of primary involvement of the crossed pyramidal tracts. Oppenheim and Dana claim that no case of this kind has yet come to autopsy. In view of these uncertainties, I have concluded to retain the older designation of spastic spinal paralysis.

The patient was a male, thirty-eight years of age, a farmer by occupation, and had always resided in the country. The family history was excellent, presenting no cases of nervous trouble or tuberculosis. The patient had always had excellent health, and denied all venereal infection. Four years before coming under observation he had a severe attack of influenza in the early spring months. From this illness he made a slow convalescence, and as the season advanced and the weather became warmer he noticed that the left side of his face did not sweat as did the right side. He is not positive that the dryness of the surface included the entire left half of the body, but does recollect that the left hand was always drier than the right. During the summer this symptom gradually disappeared. As autumn approached he observed an increasing weakness of the left arm and leg. He is not positive, but thinks this loss of strength began first in the arm. With this weakness there was an increasing stiffness of the left leg and arm. The paralysis has gradually increased ever since it began, though the progress of the disorder was more marked during the first two years.

As the patient enters the room his walk is distinctly of a hemiplegic type, and at first glance a diagnosis of cerebral hemorrhage would be made. On interrogating the patient it was learned that the disease came on gradually, that at no time was there "a stroke" or impairment of consciousness. The side of the face is not involved and there is no disturbance of speech, nor are the eyes involved.

The muscular system is well developed and he has every appearance of being in perfect health. He stands with eyes closed and feet close together, without swaying. In neither hand is there inco-ordination. The knee jerk is greatly increased on the left side, as is the elbow jerk. Myotatic irritability is exaggerated. A slight tap on the quadriceps is sufficient to throw the left leg nearly straight. There is no distinct quadriceps clonus. Ankle clonus is marked and will continue for several minutes. On the right side there is an increase in the knee jerk, though no ankle clonus is present. The patient says that in walking the ankle jerk often occurs in the left foot, and it is necessary for him to stop and press the foot firmly to the ground. It is apparent that the right side is involved to a slight extent, but it is not sufficient to attract the attention of the patient. Movements of the right arm and leg are clumsy and difficult of execution. The grasp of the left hand is nearly abolished; that of the right is especially strong and vigorous. The superficial reflexes are not altered.

Electrical reactions are normal on the paralyzed side. As compared with the opposite side, the same amount of current is required. There is no tendency to polar inversion. Sensation is not altered or diminished anywhere, nor are there any trophic disturbances. The muscles are everywhere as full and rounded on the paralyzed as on the healthy side. The pupils and eyegrounds are normal. The visual fields for white and colors are normal in both eyes. All of the cranial nerves are intact and there is no increase in the jaw jerk. Speech is not disturbed. The functions of the bladder and rectum are normal. There is no impairment of the sexual centre.

This is the first case that has come under my personal observation in which primary lateral sclerosis was practically limited to one side. I say practically limited, for it is apparent that there is a very slight involvement of the right side, though it is not sufficient to attract the attention of the patient. I regard this unilateral grouping of the symptoms in this disorder as exceedingly rare, and one to which many late writers do not refer. Bastian ("Paralyses, Cerebral, Bulbar, and Spinal," 1886) states that in rare cases the disease is limited to one side of the body, beginning, for instance, in one leg and then extending to the arm on the same side, so as to present a kind of hemiplegic distribution. In equally rare cases the upper extremities may be affected first, the disease later involving the trunk and legs.

Recently Dr. Charles K. Mills described to me a similar case which had come under his observation but had never been published. In this case the disease was of a distinctly "hemiplegic" type.

A CASE OF COMPLETE SPONTANEOUS VERSION.

By K. N. DALEY, M.D.,

BOSTON, MASS.

On May 27th, I was called to attend Mrs. C——, a secundipara, aged about twenty-eight years. No word having been left at the office as to the nature of the case, it was some few hours after I was summoned that the visit was made. The patient's house was reached at about 2 P.M., and it was learned that she had been in labor since early the previous evening. While cleaning up I had occasion to observe the character and duration of her pains, which at this time were recurring at about five-minute intervals. It seemed to me that she had not reached the second stage, and an examination made shortly after confirmed the inference, the os being of but the size of a five-cent piece; head presenting. The result of examination was made known to the patient, and she was encouraged and instructed how to work with her pains.

Soon the case seemed to progress nicely, the pains increasing in frequency and intensity. After an interval of an hour or more a second examination was made. I was somewhat surprised to find that there was scarcely any perceptible change in the size of the os, which was exceedingly rigid and felt like a tense ring of cartilage. However, the pains being strong, regular, and frequent, she was allowed to continue for another couple of hours, in the hope that with the increasing force and frequency of the contractions dilatation would eventually ensue. At the third examination (made about two hours after the second) the os had increased to about the size of a silver dollar, but still presented the tense, rigid character. Position was made out, it being a normal O.L.A.

Moral suasion was again resorted to, but by this time the patient had begun to tire and grow weak. Vomiting soon supervened and it required constant effort to keep her mind on her work. The pains also now lost their frequency, but seemed to make up for this loss by increased intensity, with, however, but little effect on the size of the os.

Manual dilatation was tried, but owing to the cartilaginous character of the os but little headway was made. There were now signs of complete inertia, and it was decided to etherize, apply forceps after complete dilatation, and then deliver. Mr. C—— was dispatched for ether, the writer meanwhile continuing the dilatation. Just at this time the membranes were accidentally ruptured and quite a rush of waters came down, but version did not occur immediately, for the head could easily be felt with the dilating hand for some few minutes later, when Mr. C—— returned with the ether.

Dilatation was suspended at this point. The head was presenting, position O.L.A., head not engaged. This was the position just previous to etherization, the os just admitting the hand. Ether was given and soon the woman was completely under its effects.

The cone was now intrusted to an attendant, it being my intention to complete the dilatation and deliver as soon as possible. The interval between my last examination and this moment could certainly not have been more than fifteen minutes, yet on introducing the hand to enlarge the os still more I was completely dumfounded to find not the head but the breast. At first I could scarcely believe my own senses, but yet there it was! I had informed the attendants of my intention, and in fact had my forceps by my side in lysol solution, all ready for instant application.

There was now but one thing to do—complete the dilatation, go up for a foot and bring it down, which was soon accomplished, and after some further slight difficulty delivery was happily completed.

Such cases are explained by Lusk thus: The amniotic fluid having escaped, the fœtus is seized by the uterine muscular walls, which now labor under a mechanical disadvantage. The pains force the head into contact with the os internum. There is absence of a distending bag of waters; the contractions at the fundus become more powerful, the os refuses to dilate, the presenting part is displaced laterally, and the part previously occupying the fundus is forced into the pelvis.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

TYPHOID EPIDEMICS—OPHTHALMIA AND SCHOOLS—DR. BARNARDO—DR. SIMS WOODHEAD—CLINICAL SOCIETY—NURSES' DISPUTES—DEATHS OF DR. HAUGHTON, SIR WILLIAM MACKINNON, AND SIR RUTHERFORD ALCOCK.

London, November 5, 1897.

THE typhoid scourge continues. At Maidstone the medical officer of health reported on Wednesday 35 new cases for the week, an average of 5 a day. The next day there were 10, bringing the total up to 1,795. He did not consider any well in Maidstone safe, and the conduit water was in constant danger of pollution. The corporation has spent about £6,000 in temporary hospitals, laundries, nursing, and such like. More than £6,000 has been subscribed to help the sick and the orphans.

At Lynn also the epidemic is unchecked. On Wednesday 17 fresh cases raised the total to 316 with 12 deaths. Yesterday 14 new cases were added. At Clifton the number of cases had risen yesterday to 120, and it was said all had been traced to one milk supply from a distant farm.

Dr. Sydney Stephenson, who, as I informed you, was appointed to examine the school children as to the prevalence of ophthalmia, has completed his report, which is now printed as an appendix to the annual report of the local government board. Among 1,702 children examined, he found 973 cases of chronic trachoma, but acute ophthalmia was rare except among pauper children. Dr. Stephenson says trachoma is certainly more common in poor-law institutions than in outside schools, but the difference is not so great as many supposed. Actual injury to eyes or to sight from trachoma occurred in 439 eyes in 277 children, and this he says is "due to a malady that is preventable and ought to be prevented." During the last twenty years great improvement has been effected in the ophthalmic condition of the children. In 1874 Mr. Nettleship found in 8,798 children trachoma affecting 42 per cent. Now Dr. Stephenson finds the percentage reduced to 4.91. Similar improvement is noted in other respects. Dr. Stephenson traces the primary cause of trachoma in the schools to importation of diseased children, and asserts that aggregation cannot be shown to exert an appreciable effect on its spread. The remedies propounded are structural adaptations and careful administration and supervision, particularly in regard to washing-arrangements and other sources of infection, together with probation of thirty days for new comers and frequent skilled inspection; medical officers to be specially trained to examine and record the condition of the eyes of every new comer, and a central hospital to intercept diseased children and detain them until cured. Seaside sanatoria and other provisions are also recommended.

I am sorry to see that Dr. Barnardo's homes do not come out well as to the prevalence of trachoma. In one of them 5.51 per cent. were affected. Of course the class of cases in these institutions must be taken into consideration as specially difficult to deal with, but I should think that Dr. Barnardo will carefully study this report and direct his best efforts to the matter. Probably most of your readers are acquainted with the great good he has accomplished. Dr. Barnardo was a student of the London Hospital. He gave up the profession for the purpose of rescuing the children who were destitute and outcasts. The work grew rapidly, and has attained such dimensions that he is now able to offer to receive and provide for the one hundred or

more orphans of the Maidstone epidemic. He found himself early in his work rather hampered by not being qualified. He therefore took his diplomas, and he has been fellow of the Edinburgh College of Surgeons since 1879.

When Sir B. W. Richardson died many people wondered whether another medical man could be found to follow up his temperance work. His successor as president of the Medical Temperance Association is Dr. Sims Woodhead, whose scientific reputation you are well acquainted with. Last week a complimentary breakfast was given to Dr. Woodhead in Dublin, by the several Irish societies engaged in temperance work. The College of Surgeons lent its hall for the occasion, and Sir William Thompson presided and said he was very glad to take part in the proceedings, and as president of the college he assured a gratified audience that the council had willingly given what facility it could to honor their distinguished guest.

There was an interesting show at the last meeting of the Clinical Society, and next week there is to be a series of cases of forcible rectification of curvature of the spine, as practised by Dr. Calot. The cases are to be brought forward by Mr. Tubby and Mr. Robert Jones. It is anticipated that M. Calot will be present and defend his method, which will no doubt be critically discussed.

The Royal British Nurses' Association has its troubles, and is hardly a bed of roses for those doctors who have devoted much time and energy to its assistance. Last week there was a meeting of its "members' rights defence committee" at St. Martin's Hall, convened by certain malcontents for the purpose of condemning the management and demanding a public inquiry into the grave charges made against the managers. Mrs. Bedford Fenwick moved a resolution to the effect that, "in view of the great public and professional interests involved, inquiry is imperatively needed," and calling on Parliament to appoint a select committee next session. In support of this she accused five medical men of controlling the association and mismanaging the finances. The meeting was not a large one—perhaps over a hundred persons were present, but they were not all nurses; in fact the uniform was not at all conspicuous. Two of the speakers who followed said they were not nurses or members, but came to support Mrs. Fenwick, in whom a subsequent speaker said she knew many nurses had confidence. A late secretary remarked on the few nurses present, and said Mrs. Bedford Fenwick did not represent either the association or the nurses and had called this meeting only because she had been omitted from the council. Hereupon storms of hisses and applause conspired to interrupt the proceedings, and the resolution was declared to be carried. Sir C. Browne, Dr. Bezley Thorne, and Messrs. Pick, Langton, and Fardon are the gentlemen who are accused of mismanagement by Mrs. Bedford Fenwick and her husband, but what the association would gain by transferring to the latter the confidence felt in the former requires explanation.

The foremost professor of Dublin University, the Rev. Samuel Haughton, M.D., D.D., died on Sunday, and will be missed by an immense number of graduates who can hardly realize Trinity College without Haughton as the most prominent figure. He entered the university in 1839, and crowned his brilliant student career by winning the fellowship the very year he took his B.A. (1844). Ever since he has been closely connected, I may say identified with the university, in which he has held every important office. He took the M.D. in 1862 in order to qualify himself for the registrarship of the School of Physic, and no sooner was he installed than he began a series of reforms which gave new life to the school and in fact set the tone of medical education in Dublin. He was a great mathematician, a naturalist of a high order, and possessed most remarkable mental gifts, so that any subject to which he gave attention was at once mastered by him and not seldom advanced. With all this he was an eloquent exponent of science, a public speaker of such power as always to attract an audience and always please—a born orator in fact, with a full dash of rare Irish humor. For several years he represented his university in the General Medical Council, where his wit and humor enlivened the usual deadly dull proceedings, and where if he met his equals in intellect there were certainly none who excelled him. Honorary degrees of Oxford, Cambridge, Edinburgh, and foreign universities were conferred upon him. Among his works his "Principles of Animal Mechanics," published in 1873, is perhaps best known to the profession.

Sir William Mackinnon, K.C.B., formerly director-general of the army medical department, died on the 28th ult., aged sixty-seven years. He was F.R.C.S. Edin., 1873, licentiate of 1851. The Irish College conferred upon him an honorary fellowship. Sir William Russell in *The Times* says: "He was one of the best and bravest soldiers that ever wore the uniform of the Queen, but it conveyed no idea of the man himself, who was an embodiment of some of the finest traits of the Celtic Highlanders."

Sir Rutherford Alcock, K.C.B., D.C.L., F.R.C.S., died on Wednesday morning, aged eighty-eight years. He had left the profession so long ago and had become so notable in the diplomatic service that many were unaware that he ever belonged to us. He was on the medical staff of the British forces in the peninsula, and received honors and decorations from Spain and Portugal. Afterward he was consul in China, and subsequently plenipotentiary to Japan and our first minister to that country. Still later (1865) he had the same position at Pekin, and six years later retired. He had been president of the Royal Geographical Society. He took an interest in hospital work, in the course of which I came into contact with him. His help was specially valuable and highly appreciated at the Westminster Hospital. He published "Notes on the Medical History of the British Legion in Spain" and other works, among which I may mention those on "Japanese Art and Industries," and a Japanese grammar and dialogues in that language.

OUR BERLIN LETTER.

THE LEPRA CONFERENCE—SOME NEW DATA CONCERNING THE HUMAN PANCREAS—PARASITIC SKIN DISEASES.

THE International Lepra Conference began its sittings on the 11th of October at the imperial health department's building in Berlin. About one hundred and fifty physicians and representatives of almost all cultured nations were present. Virchow was chosen president; and Lassar (Berlin), Hansen (Norway), and Ehlers (Denmark) were named as an advisory committee. The session was addressed by Minister Posadowsky, who said that the government took a deep interest in this much-contended question.

Of the many congresses held this summer in Berlin, the lepra conference awakens perhaps the most interest, because of the practical results for our battle with this horrible scourge which will result from the conference of so many authorities. Hence the deep interest of all governments. We Germans are concerned in preventing that little epidemic which, as

mentioned in a previous letter, exists in the eastern part of Prussia, from spreading over the entire empire. The government has ordered the building of a lepra home, and that all sufferers be brought to this isolation station and there treated in the most humane manner. Without these precautions, Armauer Hansen, the celebrated discoverer of the lepra bacillus, declares nothing can be attained.

Representing France, Besnier (Paris) spoke of the danger of the spread of the pest through the nasal secretion, for multitudes of bacilli are to be found in this secretion, and it is to be easily understood how dangerous an unclean person is for his neighors. In agreement with this fact, we often find the first manifestations of leprosy on the nose, or rather some part of the face.

Armauer Hansen (Norway) pleaded for a humane but strict isolation of the lepers. The majority must not be placed in danger because of the benefit thereby resulting to the minority; and even the greatest pity we may feel toward these unfortunates must not influence us to endanger the welfare of an entire nation. The speaker then showed how the extra expenditures for the care and provision of lepra cases had repaid, for under this system the number of cases diminished year by year.

England's delegate advocated the theory that in the habitual eating of fish was to be found the main factor in the etiology of leprosy; an opinion not shared, however, any longer by other lepra authorities.

A number of other purely scientific questions and problems took up the time of the conferrees. A most friendly spirit prevailed all the time.

The Berlin Dermatological Society held a festive session at the Langenbeck-Haus, in honor of the conference. The hall was prettily decorated, and every seat taken. In the front rows, in addition to the delegates, were among others of prominence the Kultus Minister Bosse, Professors Virchow, Jolly, and v. Bergmann. Professor Lassar opened the session with an address of welcome in the German, French, and English languages, closing with a German cheer for the Emperor. He followed with a paper on "Venereal Diseases and Public Health." This concluded, he ascended the platform and announced that the Dermatological Society had elected Rudolph Virchow an honorary member of that body. Here followed projected pictures on the screen, illustrating many cases of interest of leprosy and lupus. This closed the session, which was followed by a supper.

At the close of the conference the members and delegates were invited to a banquet given by the Kaiser. A special train brought them to Wild Park, where the royal coaches conveyed them to the New Palace. The Kaiser presided at the table. His wife and all the children were present. He conversed frequently, especially with Virchow; likewise the Empress. Minister Bosse and Professor Lassar introduced the gentlemen. The Emperor passed from one foreign delegate to the other, saying a word or two to each one. He assured them that his interest in the question had led him to become well acquainted with it. Meanwhile refreshments were served, and every body felt at ease; time passed quickly, so that the original time set (one hour) was long passed when the imperial couple withdrew. Thus closed the conference.

At the first autumnal session of the Verein für innere Medicin, v. Leyden, addressing the meeting, paid his respects to three great men who had passed away during the vacation. Fresenius, Heidenhain, and Oertel are men whose fame extends farther than do Germany's borders; the entire world recognizes their merit and labors. v. Leyden also spoke of the active interest of Germany in the international congress at Moscow. He believed the German scientists could with complacency regard the laurels they had plucked there.

Stadelman spoke about the lumbar puncture and his experience with one hundred cases. These included meningitis tuberculosa, meningitis purulenta, abscessus cerebri, brain tumors, and cerebral hemorrhages, etc. He summed up as follows: For diagnostic purposes, a positive result only is to be considered; a negative one is of no value. As regards therapy, lumbar puncture is of no benefit; on the contrary, its employment is often contraindicated, especially in cerebral hemorrhage, as it tends to make the condition worse.

At the first meeting of the Berliner medicinische Gesellschaft, Blascko presented a case of leprosy.

An improvement of the Roentgen photography was reported by Levy-Dorn. It consists in the placing of a fluorescing screen made up of a layer of fine granules of tungstate of calcium. By means of this improvement the exposure is diminished and at the same time the pictures are made sharper.

The greatest interest was awakened by the reading of Buschke's article, "Yeast Fungi of the Human Skin and the Disorders Caused by Pathogenic Fungi." Buschke observed a woman with ulcerating tumors of the skin. He discovered, by means of cultures and inoculation, the cause to be a yeast fungus. This is the first case of blastomycosis positively recognized in man. This case led Buschke to further investigation, to ascertain if variola, syphilis, and carcinoma were not caused by fungi. There are yeast plants which grow upon the exterior and penetrate into the tissues and blood. This variety Buschke studied experimentally. A yeast plant obtained from a cervical discharge was cultivated. If from this culture a portion was brought into the conjunctiva of animals, sarcoma-like swellings were produced and then universal blastomycosis. On the other hand, Buschke could not produce any blastomycosis from malignant growths of man. The peculiar round bodies seen and described by some authors in this condition (blastomycosis) are certainly not yeast growths. Buschke's investigations have yielded a negative result as regards the etiology of carcinoma; still they open to our view a new perspective of the pathological new growths.

ONE OF THE CAUSES OF THE ABUSE OF CHARITY AT OUR DISPENSARIES.

For the Medical Record.

SIR: Much as has been said and written on the subject of the abuse of charity at our dispensaries, one very important factor in its causation has been quite overlooked. I refer to the part the family physician has taken in the past, and is still taking, in greatly increasing the number of persons who apply for gratuitous treatment. Most of our dispensaries are devoted to the specialties. The family physician has, for instance, a patient who, he thinks, should be treated by a specialist. The patient, although in moderate circumstances, is able and in many cases perfectly willing to pay for treatment. Instead of being sent by the family physician to the office of a specialist with a note asking consideration for the patient in the matter of fee, he is told to go to a dispensary (the physician generally designating the one on which he confers the privilege) and receive free treatment.

I have been engaged in dispensary practice in New York for twenty-five years, and I do not hesitate to assert that in my opinion the family physician is largely responsible for the abuse which is now acting as a boomerang against himself.

It is not an uncommon occurrence at my clinic to

have well-dressed persons apply for treatment. After ascertaining residence, occupation, etc., I inquire: "Do your circumstances compel you to apply for treatment at this place, which is intended for the poor only?" The answer almost invariably is: "I am able to pay something, but my family physician told me to come here and I would receive free treatment." Sometimes they coolly inform me that they have been sent to the dispensary for opinion only, and that the family physician merely wanted to feel assured that his own diagnosis was correct. It goes without saying that such cases are refused treatment at my clinic. New York has no lack of specialists, many of whom are young men who would gladly, if such cases were referred to them at their offices, give them treatment at prices they could well afford to pay. If this were done, the clinics at many of our dispensaries would soon rapidly decrease in the number of unworthy persons applying for treatment.

CLINTON WAGNER, M.D.

19 EAST THIRTY-EIGHTH STREET.

EPISTAXIS IN TYPHOID FEVER.

To the Editor of the MEDICAL RECORD:

SIR: Some recent remarks in the MEDICAL RECORD upon certain symptoms in typhoid fever lead me to call attention to an important symptom, clinically and practically, to wit, epistaxis.

About ten years ago I observed that in this disease perforation of the nasal septum near its facial border sometimes occurs. This led to the examination of every case of hemorrhage, and uniformly it was discovered to be from the same point, situated about one-quarter or one-third of an inch from the outer margin of the septum on one or both sides. Observance of this fact will give the attendant immediate control of the hemorrhage by placing and holding the finger over the bleeding point. A few moments' pressure over the alæ, continued, will often be sufficient. While I have not verified it, my impression is that hemorrhages occurring in low states of the system are from the same region.

R. W. ERWIN, M.D.

[illegible]

A NEW OPERATION FOR MALIGNANT DISEASE OF THE TESTICLE.

To the Editor of the MEDICAL RECORD:

SIR: In referring to Dr. J. Coplin Stinson's article with the above title in the MEDICAL RECORD of October 30, 1897, I would suggest that many practitioners have seen many cases of large and painless induration of the testicle and scrotum disappear quite readily under the proper administration of the iodides, or iodides and mercury. A painless carcinoma is so rare that it may be said practically not to exist at all.

As Dr. Stinson did not do the entire radical operation suggested, owing to the fact that the inguinal glands had been previously removed, it opens a doubt as to the mortality rate being "about *nil*." It shortened and simplified his one operation to leave out the extensive dissection necessary to remove the inguinal glands. Dr. Stinson's operation is novel, but the principle of removing all possible source of infection when operating for malignant disease in any part of the body accessible to operation is just as old as ever.

Dr. Stinson does not state whether or not a microscopic confirmation of the diagnosis was made by preparing slides from the tissues removed.

E. H. SMITH, M.D.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 20, 1897:

	Cases.	Deaths.
Tuberculosis	240	93
Typhoid fever	21	4
Scarlet fever	153	10
Cerebro-spinal meningitis	6	3
Measles	255	16
Diphtheria	151	10
Laryngeal diphtheria (croup)	1	4
Chicken-pox	17	

Opium Eating among the Kaffirs.—It is reported that opium eating has become a habit with the Kaffirs. The Chinese are said to be the chief purveyors, though the trade is by no means restricted to them.—*Hospital.*

The Alleged Heredity of Consumption.—There is no doctrine more firmly impressed on the mind of the average director of a life insurance company than the hereditary transmission of consumption. Yet, like all cherished beliefs, this doctrine is being attacked on all sides, and if it is to remain as one of the fundamental principles of life insurance, fresh statistics must be collected, so as to confute the statements confidently made by its opponents. There can be little doubt that in many of the so-called cases of transmitted phthisis the patient acquired the disease by contagion, his powers of resistance to the bacillus being enfeebled by the same conditions of environment as led to his father or mother being affected. In order therefore to prove that consumption is inherited, it will be necessary to show that the children of consumptive parents, when removed from the influence of the parental environment, succumb to the disease to a greater extent than do the general population.—*British Medical Journal.*

Self-Sacrifice.—A recent issue of a Western eclectic journal contains a page of editorial notes. The first note is headed "Be Good to Yourself." Further down the page is another, entitled "Consultations." It reads: "Our physicians are isolated, and find it difficult to get aid in consultations and surgical operations; but we are determined to give all the assistance in that direction that is possible. We travel a good deal by rail for consultations, and sometimes remuneration is hardly what we would have made by staying at home; nevertheless we are desirous of giving strength to our cause."

Even in Old Roman Days!—

> Wise Arruns, asked "How long will Caius live?"
> Replied, "Three days the fatal sisters give;"
> And Arruns knew the prophet's art. But lo!
> Stronger than gods above or gods below,
> Euschemon comes; his healing arts he tries,
> And in a single day poor Caius dies.
>
> —*Spectator*, August 28, 1897.

Astigmatism in German Schools.—In the majority of instances of weak-sightedness, as well as in structural disease, and in some instances of accommodation error, the origin has been in astigmatism which has passed unnoticed. In examinations of twelve hundred eyes, over sixty per cent. were found more or less astigmatic, while one hundred and five were myopic and one hundred and eighty-eight hypermetropic. —STEIGER, *Correspondenzblatt für Schweizer Aerzte*, May 15, 1897.

Appendicitis has been simulated and operation performed in a case observed by Picque (*Le Bul. Méd.*), in which a pus collection in the diverticulum of Meckel had been the origin of the symptoms.

Infantile and Hereditary Multiple Sclerosis.—Eichhorst (*Virchow's Archiv*, Bd. 146, Hft. 1–3) claims that previously reported instances of infantile multiple sclerosis will not bear the closest critical scrutiny, and that most of them are to be regarded as diffuse sclerosis of the brain. He relates two instances of multiple sclerosis in mother and son confirmed by autopsy, the son having died at the age of eight years. Anatomical changes were found in both instances only in the spinal cord, although nystagmus, disturbances of speech, and pronounced psychical changes were present. This is, however, not so much to be wondered at, since the typical picture of multiple sclerosis may be present without organic lesion.

Quackery.—To gain some idea of the profits of quackery, consider the fact that in one year, 1890, the manufactories of patent medicines in the United States sold their products for $32,622,123. Now if the retailers doubled the price to consumers, as is more than probable, then the people of this country paid for their patent medicines, which very surely do much more harm than good, money enough to have paid every one of the 104,805 "physicians and surgeons" of the United States an annual income exceeding $600.—Dr. Chaillé, *New Orleans Medical and Surgical Journal*, May, 1897.

To Determine Age of Fœtus in Miscarriages.—Dr. Lambinon gives the following figures, obtained at the Liège Maternity, bearing upon the weight of the placenta in cases of miscarriage. The average weight of the placenta at 6 weeks was 20 gr.; at 90 days, 67 gr.; 120 days, 111 gr.; 165 days, 262 gr.; and at 235 days, 330 gr.

The Prevention of Tuberculosis.—At the Twelfth International Medical Congress, held in Moscow, Dr. V. C. Vaughan concluded a paper with the following propositions: All milkmen should be provided with a license from the municipality; such a license not being granted until the cattle have been inspected by a competent veterinarian, who should apply the tuberculin test in every instance, and any animal found suffering from tuberculosis should be immediately destroyed. Cattle killed for food should also be subject to skilled inspection. The disinfection of sputum from consumptive individuals is absolutely necessary, and such persons should not be allowed to expectorate in the streets or public vehicles. Houses and rooms which have been inhabited by consumptives should be disinfected. The government should construct, equip, and maintain hospitals for paupers suffering from tuberculosis; such hospitals should be divided into two classes—one for incurables and the other for those who may recover. Tuberculosis in its early stage is a comparatively curable disease; therefore persons yet in this stage should be examined once or twice a year by a physician, and the government should furnish physicians to make such examinations for the poor.

Anti-Football. — The most weighty deliverance that this fall's discussion of football has called forth is the article from the Medical Record, which we reprint in "The Revolt against Football" column. The Medical Record is a conservative medical journal of the highest standing, which speaks with authority on the subject of physical training, and its words must have great influence with people who keep their heads steady in the whirl of excitement that comes with the ending of the season. The Medical Record holds that the game as now played ought not to be allowed, on the ground that it can no longer be viewed in the light of innocent recreative amusement, with harmless and healthful athletics as its object; but that, even with "slugging" ruled out, it is "productive of the greatest variety of surgical injuries to every part of the body," and that the effect of such injuries is lifelong in a large proportion of cases. This is a phase of the subject which is seldom regarded, except by the medical profession. Unless a player is so badly hurt that he cannot enter the field again during the season, the injury is generally dismissed by both the young man himself and the public as a mere trifle, while really he may suffer the effects always, and more severely as he passes on from middle life into old age. —*New York Evening Post.*

Health Reports.—The following statistics concerning yellow fever and small-pox have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended November 20, 1897:

		Cases.	Deaths.
Yellow Fever—United States.			
Alabama, Flomaton	November 17th	1	
Mobile	November 13th to 19th	13	1
Louisiana, New Orleans	November 14th to 19th	49	12
Mississippi, Biloxi	November 14th to 19th	6	1
Clinton	November 13th to 19th	3	
Edwards	November 13th to 19th	5	1
Scranton	November 13th to 19th	11	1
Yellow Fever—Foreign.			
Cuba, Manzanillo	October 17th to 31st		5
Matanzas	November 3d to 10th		2
Jamaica, Port au Prince	November 10th		1
Small-Pox—United States.			
Georgia, Atlanta	November 14th to 17th		1

Books Received.

While the Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

ACUTE SEROUS MENINGITIS (ALCOHOLIC MENINGITIS, WET-BRAIN).[1]

BY CHARLES L. DANA, M.D.,

NEW YORK,

PROFESSOR OF NERVOUS DISEASES, BELLEVUE HOSPITAL MEDICAL COLLEGE; VISITING PHYSICIAN TO BELLEVUE HOSPITAL

THE description I am about to give of so-called alcoholic meningitis is based upon twenty cases observed during life and examined after death macroscopically and in most cases microscopically. The observations were controlled by clinical and autopsical studies of a case each of pernicious anæmia, suicide, purulent meningitis, cerebral tumor, uræmia, cancer of the pylorus, and morphine poisoning. Most of these patients died in terminal conditions suggestive of the last days of alcoholics. I have also had careful notes taken by Dr. A. J. Brown, Dr. Gardner, and Dr. Daley, of cases of "alcoholic meningitis" which ended in recovery. Out of this material I have constructed a picture of what is known in the hospitals as "wet-brain," or "alcoholic meningitis," and what I have termed serous meningitis. This term is not strictly correct, as I shall show; for the process is not so much an inflammation as it is a toxæmia leading to congestion, then to an œdema both of the brain and its membranes, with a moderate serous effusion into the ventricles and decided disorganization of the brain elements. But the clinical picture is strikingly like that of true meningitis.

Etiology.—The disease occurs oftenest in men simply because of the more frequent indulgence of the male sex in alcohol. It rarely develops until a person has been drinking eight or ten years, and consequently affects people oftenest between the ages of thirty and forty. The exciting cause is commonly alcohol, and in this country whiskey or what are known as "hard drinks," but beer and ale will accomplish the same result. I have rarely seen the disease in wine drinkers. The persistent use of morphine, cocaine, and chloral may lead to much the same condition. The patients often have some tuberculosis, or sclerotic changes in the arteries, and perhaps cirrhotic liver and kidneys. The exciting cause is usually a continuous drinking-bout of two or three weeks, ending in delirium tremens. The delirium tremens, however, is not by any means always present. The patient may pass directly from a condition of prolonged intoxication into the condition of alcoholic meningitis or "wet-brain."

Symptoms.—In case delirium tremens has occurred, the patient after two or three days of prolonged delirious excitement gradually sinks into a semicoma. This is accompanied by a muttering delirium. The patient is sufficiently conscious to have flitting delusions and hallucinations of sight and hearing. At this time he is able to drink and take food; the pulse is rather rapid, the temperature is usually normal or may be raised one-half or one degree. The skin is hyperæsthetic, and pressure upon the muscles of the arms or legs or abdomen causes pain. The patient rarely complains of headache, as in acute meningitis, and he has no explosive vomiting. The pupils are usually rather small. Often at this time conjunctivitis and keratitis appear.

After a few days the patient's stupor becomes deeper and he can be aroused only with difficulty. The arms and legs are now somewhat stiff, the reflexes are exaggerated, the neck is stiff and slightly retracted, and attempts to move the head bring out expressions of pain. Indeed, the stiffness is in a measure voluntary, the patient resisting directly attempts to move and bend the limbs. There are no jerking, jumping, or convulsive movements. The abdomen is retracted and the skin and muscles are still very hyperæsthetic. The lids are nearly closed; the pupils are small and do not react well to light. The tongue is coated and usually dry, and urine and fæces may be passed involuntarily. The patient may linger this way for several days more. The pulse becomes rapid and feeble, the extremities are stiff and cold. The skin is dry and loses its elasticity, so that when pulled up between the fingers it stays in folds. "Putty skin" is a good name for this. The coma deepens, the temperature may rise to 103° or 104° F., and symptoms of pneumonia may appear as the scene closes, the duration of the attack being about ten days. On the other hand, in some cases the patient does not pass into the worst stage, the mind becomes clearer, the hyperæsthesia lessens, food is taken better, and the bowels are moved voluntarily. Improvement continues, and in three or four weeks the convalescence begins.

Some special clinical observations were made for me by Dr. A. J. Brown. In ten cases the blood was examined. He found in all a diminution of red blood cells, the average being about four million per cubic millimetre. The hæmoglobin was also diminished, the average being seventy per cent. Evidence of degeneration of the red blood cells and of poikilocytosis and leucocytosis was often noted.

The urine noted in two cases showed excess of urea and earthy phosphates. Albumin was found once, and this was due to an old nephritis.

Electrical tests of the muscles showed uniformly a lessened irritability to the faradic current. The deep and superficial reflexes were usually exaggerated until the latest stage, when they were diminished.

Careful examination of the eyes was made in a number of cases by Dr. A. E. Davis, who reported his results in *The Post-Graduate*. He never found optic neuritis; in the early stages there was congestion of the fundus.

Pathological Anatomy.—Besides autopsies made under my own direction, I have a number of careful reports from Dr. H. Brooks, of the Carnegie Laboratory.

In cases of short duration in which the delirium has hardly abated or in which a pneumonic fever has complicated the course, the meninges are congested; but in the typical prolonged cases this congestion is only moderate. The dura is often thickened; rarely it is

[1] Read at the meeting of the Practitioners' Society, October 15, 1897.

adherent in places to the pia. The pia is thickened and opaque just about in proportion to the age of the patient and duration of the alcoholic habits. It sometimes shows hemorrhagic patches. There is considerable serous fluid in the subdural sac and in the subarachnoid spaces. The ventricles are usually found dilated and contain an excess of fluid, but are not often extremely distended. The brain when cut into is rather pale, soft, and shows punctate hemorrhages, especially in the deeper parts and in the pons. Occasionally one finds points of hemorrhagic softening, similar to those described as hemorrhagic encephalitis.

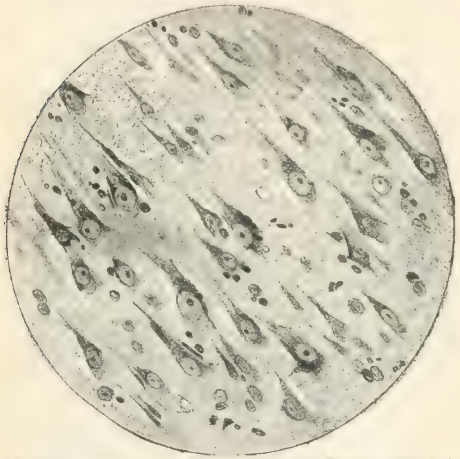

Fig. 1.—Male, Thirty-four. Alcoholic "meningitis," seven days, mid-central convolution. × 1/2 in. Pericellular dilatation and infiltration.

Microscopic examination shows in the uncomplicated cases that there is no true inflammatory process. There is often congestion, but not always; the commoner condition is an œdema of the brain tissue, the perivascular and pericellular spaces being dilated. The nerve cells show conditions of degeneration such as one might expect if they were attacked by an irritative and destructive agent, which agent had not markedly affected the vascular conditions of the part. The cortex may even be somewhat pale, and often shows the evidence of œdema in the dilated perivascular and pericellular spaces. The cell bodies themselves show, in very acute and febrile cases, a great degree of pigmentation, and in some cases the masses of pigment occupy more than half of the body of the cell. In the pyramids these deposits are usually at the base, in the region of the axis-cylinder process; in some of the spindle-shaped cells of the deeper layers the pigment is seen deposited between the nucleus and the apex of the cell. But in the ordinary types of wet-brain I found but little abnormal pigmentation. The cytoplasm shows a loss of the distinct chromophilic markings, and looks as though these bodies had been broken up into granular masses. The body of the cell sometimes looks as though it were made up of minute fatty granules. Sometimes the granular masses have dropped out of the cell into the perivascular space. The pigmentary changes are always most striking in the large cells. The changes are by no means uniform, but appear to affect certain areas, and are much oftener seen in a typical fashion in the cortex of the central convolutions than in the occipital or frontal lobes. The cell processes are still fairly perfect, at least many of them, and at times the chromophilic granules can be well seen at the roots of the cell processes, especially the axis-cylinder and the apical process, though the cell body may be in a very damaged condition. Nothing is so striking throughout the whole of the brain cortex as the preservation and great integrity of the nuclei and nucleoli. In the smaller pyramids, in which the body subtance is relatively less in amount, these nuclei are often stripped almost entirely of the surrounding cytoplasm; but the nucleus itself usually remains unchanged in form and size. The chromatic network is not easily made out, however. The nucleolus loses its sharp outline, and shows ragged edges, becoming star shaped, and sometimes being thinned out into a line. As the cell body degenerates and is dropped off, the nucleus becomes more and more nearly free, and the nucleolus can be seen approaching the line near the periphery of the nucleus. A vacuole is sometimes seen in the nucleolus, but never in the cell body in good specimens. It is a pretty well-established fact that in the nucleus, with its nuclein or nucleic-acid compounds, takes place the constructive metabolism of the cell. When this part is destroyed, the cell may live for some time, but it cannot regenerate or longer perform its functions. On the other hand, if the nucleus still remains intact, the capacity of the cell to throw out a new body and reconstruct itself is still present.

In the brains of alcoholics which I have examined, there is throughout the transverse section a striking integrity of the nucleus, and I attribute to this the fact that, despite the most severe intoxication with alcohol poisons, the individual may still recover perfectly his former mental powers.

The smaller blood-vessels sometimes show thickened walls and the evidence of a general arterial sclerosis.

Pathology.—Persons suffering from acute alcoholism, and who have afterward died in that condition, have come to the hospital with this history: First, that they have been hard drinkers for a good many years, or else moderate drinkers with periodical sprees; next, that they have been drinking very hard for two or three weeks previous to admission; third, that they have practically eaten nothing for a number of days, having sustained life by copious libations of beer and whiskey, intermixed with gin, a little beef tea, milk, and vichy, and occasionally some soft food. Finally, these patients, for some days before death, are lying in a condition of coma, with a little fever, or else are in active delirium, with a considerable degree of fever.

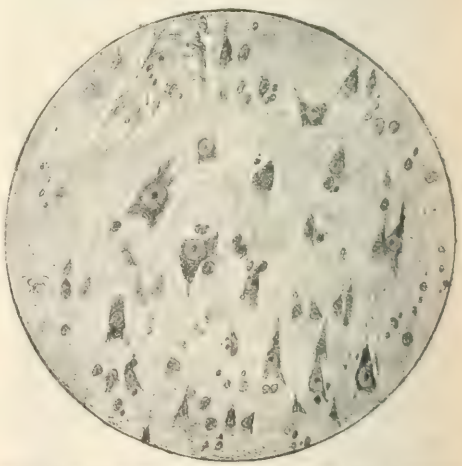

Fig. 2.—Male, Thirty-six. Alcoholic "meningitis," ten days, mid-central convolution. × 1/2 in. Pericellular dilatation and infiltration, cytoplasmic degeneration.

The conclusion that I draw from these conditions is that death in such cases is not caused in any large degree by direct poison from alcohol, but is due much

more to exhaustion and starvation, which probably lead to the development of leucomains or toxic products of some sort, the result of the disturbed metabolism. The pictures, therefore, of cell degeneration in persons who die of acute alcoholism do not represent the same things that one would get in producing acute and excessive alcoholic poisoning in animals by the injection of massive doses of the drug.

It is probable that the injured cells, losing their vitality, throw off products of acute degeneration. These morbid chemical products lead to a vascular relaxation or other morbid state of vessel walls; serum is poured out for the purpose of dissolving and carrying away the products of cell degeneration. This process is a serous exudation, which, being a reaction to an irritant, is protective to the organism, and may therefore be classed as inflammatory, using that word in its broadest sense. If this serous exudate could be rapidly withdrawn, so much poison would be taken from the system, and the parts would heal just as when the pleural effusion is removed. This furnishes a certain rational basis for the treatment to be referred to later.

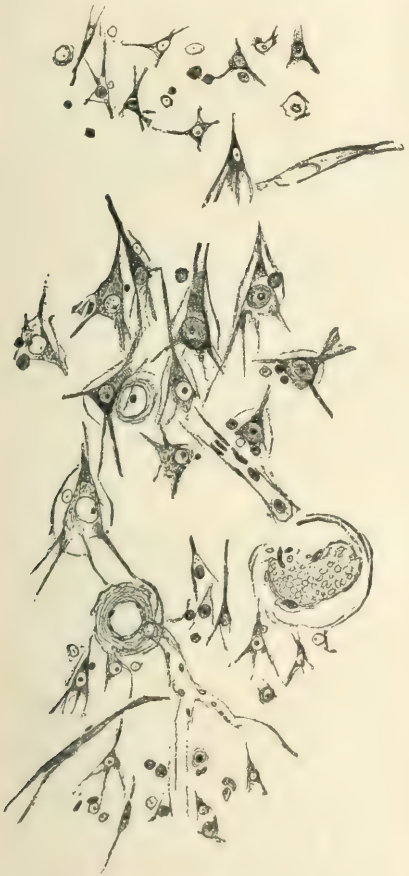

FIG. 3.—Male, Forty. Delirium tremens, followed by "meningitis," four days. Cells of three layers of mid-central convolutions. × 1/10. Granular degeneration of cell bodies, pericellular infiltration, arteriosclerosis.

Diagnosis.—The diagnosis of the disease is to be made from ordinary suppurative meningitis, from acute serous meningitis due to infection, and from acute encephalitis. In most cases the history of the patient is quite sufficient to establish the diagnosis. The symptoms of themselves are almost identical with those of ordinary acute suppurative meningitis. The only distinctions which I have been able to observe are that in suppurative meningitis there is more fever, there is less of the low delirium, hallucinations are rare, and there is an earlier and more profound coma. In other words, it is an acuter and more severe malady than alcoholic meningitis. The absence of convulsions and paralysis and the presence of hyperæsthesia, rigidity, and contracted pupils, as well as the absence of pyrexia, are usually sufficient to distinguish the disorder from encephalitis or encephalitis complicated by alcoholic meningitis.

Prognosis.—The prognosis is bad when the disease has become well developed with fever and when decided coma and rigidity have set in. Most cases not seriously complicated with other diseases get well. A prognostic criterium which I have long used and which is fairly accurate is this: if the patient has not a stiff neck he will get well, but when stiff neck comes on the patient dies in the majority of cases.

Treatment.—The treatment of the disorder should be instituted at the very beginning. If there are still any relics of the debauch, as shown in the condition of the stomach or intestinal tract, the stomach should be washed out, and at all events a thorough purge should be given. The patient should then be fed most liberally with hot milk given every two hours; beef tea and an egg beaten up in milk may also be given, and the condition of practical starvation should always be borne in mind. Stimulants in the shape of whiskey should not be administered if it is possible to avoid them, but strychnine in doses of one-sixtieth of a grain every two hours is often useful. An ice cap should be applied to the head, and at times leeches or large blisters seem to be useful applied to the back of the neck. The patient, however, should not be much depleted. When he becomes comatose it means that the ventricles and arachnoid cavities are becoming filled with water. At this time tapping the spinal cord may be tried. I have done this in about fifteen cases, and have at times removed two or three ounces of fluid with some amelioration of the symptoms and never any bad results. In one case the patient improved at once, and finally recovered. In the others improvement was only temporary.

REPORT OF THE PROGRESS MADE IN THE TREATMENT OF LARYNGEAL TUBERCULOSIS SINCE THE LAST INTERNATIONAL CONGRESS.*

BY J. W. GLEITSMANN, M.D.,

NEW YORK CITY,

VICE-PRESIDENT OF THE LARYNGOLOGICAL SECTION OF THE INTERNATIONAL MEDICAL CONGRESS; PROFESSOR OF LARYNGOLOGY AND RHINOLOGY, NEW YORK POLYCLINIC; CHAIRMAN OF THE SECTION OF LARYNGOLOGY OF THE NEW YORK ACADEMY OF MEDICINE; LARYNGOLOGIST TO THE GERMAN HOSPITAL AND DISPENSARY, ETC.

WHEN I was honored by the committee of our section with the request to open jointly with Dr. Ruault the discussion on the progress in the treatment of laryngeal tuberculosis, I was of the opinion that it would facilitate our work and enhance the value of our contribution, if, with the magnitude of the subject before us, a division of the different topics could be arranged, as in this case each of us could devote himself entirely to the task assumed, and unavoidable repetitions would be obviated. As Dr. Ruault has expressed the desire to treat the subject in its entirety, I apologize

* Paper read by invitation to open the stated discussion on laryngeal tuberculosis in the section on laryngology and rhinology of the Twelfth International Medical Congress, Moscow, August 20, 1897.

beforehand if I should tread upon ground already covered in his discourse.

It is my intention to give in this report a critical review of the development of the treatment of laryngeal tuberculosis, to mention in this connection the remedial agents introduced since the last international congress, and to conclude with remarks on the surgical treatment, to which I have paid attention for several years. In this manner I hope to keep my paper within reasonable limits, to avoid repeating what has already been said, and to be able to present one or two new contributions to the treatment, which I shall submit to your consideration and criticism.

The time is certainly within the memory of several of us when laryngeal tuberculosis was considered a *noli me tangere*, and was best left alone. Fortunately this period has passed by, never to return, although the results obtained and our power to effect a cure are still more limited than the exertion and the devotion of many of our best men to this special subject would merit. But if our earnest efforts fail sometimes, we must not forget, as Semon[1] very appropriately says, when speaking of the prognosis of laryngeal tuberculosis, that it is merely a local manifestation of a general infectious process, and that we cannot promise to cure the latter, even when successful in arresting for a time the laryngeal complication. On the other hand, we have learned; and we feel justified to subject to treatment, and if necessary to use energetic means, patients in whom we know beforehand that a cure is impossible, but whose sufferings we feel called upon to relieve. The fact that we are now able to give relief, even when we cannot cure, is certainly in a great measure due to our modern methods of treating laryngeal tuberculosis. When I make this statement I do not mean to underrate in the least the brilliant results, obtained by many of us, which terminated in a permanent cure of the larynx in a number of cases by employment of different means. But the proportion of cases cured to the vast number of sufferers is very small, and many whose larynges ultimately healed succumbed to the concomitant pulmonary disease. Let us hope that the efforts made now in all parts of the globe to master the latter may before long be crowned with success, when we can expect that the number of hopeless laryngeal cases will decrease and our work be less subjected to criticism than it is at the present time.

The treatment of laryngeal tuberculosis can in my opinion be very properly divided into three chapters: the medicinal, the local, and the surgical, although a combination of two or of all three methods is often advisable and necessary.

As to the employment of medicinal agents. I always endeavored to improve the general and the pulmonary conditions, thereby influencing favorably the laryngeal lesion. I cannot share the absolute negation of the utility of the creosote preparations, as stated by Stoerk,[2] but prefer to give the carbonate combinations. I have seen improvement follow after the use of carbonate of guaiacol and, still more, benzozol, especially at the beginning of the disease. Leaving the other well-known drugs out of consideration, I have also tried to treat a number of my patients with injections of tuberculin and its products, and with serum. The tuberculin injections made years ago did not satisfy me, although I am not prepared to deny their value in pulmonary affections if properly used. I have no experience with Maragliano's serum, and the new tuberculin of Koch is of too recent a date to allow of any report on its definite value.

Under local or topical treatment I understand atomization, inhalation, insufflation, injections, and pigments. The three agents named first will always retain their place in the therapeutics of laryngeal tuberculosis; and inhalations and insufflations have been for some time and are even now employed as curative agents, although Hajeck[3] says that he has never seen an ulcer of undoubted tuberculous nature heal from the application of antiseptics alone. You will spare me their enumeration, the more so because I have no new drug to add to the list. Rosenberg's injections of menthol in olive oil are known to all of us. Recently Botey,[4] who began experimenting as early as 1890, claims to have seen improvement from tracheal injections of creosote and guaiacol in laryngeal and pulmonary tuberculosis. He injects a one to two per cent. solution in olive oil, with a suitable syringe, in doses gradually increasing from three to twenty grams. His statement of the results obtained is as follows, viz.: That in more than half the number of patients the pulmonary symptoms had remained stationary, the expectoration and the cough had lessened, and the general nutrition had improved. About half the number of patients he claims to have cured by two months' treatment. Similar data are given by Barton,[5] who gave intratracheal injections of benzoinol, europhen, and menthol to ten patients, three of whom had pulmonary phthisis, with considerable improvement. I have also used these injections, with agreeable results, in chronic bronchitis and tracheitis, but confined myself to atomization of these compounds in laryngeal tuberculosis, considering these remedies less effective for a cure than for an amelioration of distressing symptoms, which purpose they fulfilled.

Of all the remedies applied locally in the larynx, and we might almost say of all the means employed in the treatment of laryngeal tuberculosis, none enjoys such universal consensus of opinions as to its efficacy as the application of lactic acid, introduced by Krause in 1885; and it is gratifying to note that there is an equal harmony in regard to the manner of its application, as well as to the indications for it. Scepticism is for once subdued, and as much as one may feel disappointed in the value of a remedy, and criticise its indications, which has proved useful in another's hand, Krause's discovery has, to my knowledge, no opponents at present.

Similar results have been observed from the use of sulphoricinate of phenol, which has found an ardent advocate in my honorable confrère, Dr. Ruault,[6] whose report, based on extensive and painstaking studies, is before you. I have nothing to add to his remark, except that his statements are supported by others, among them Heryng,[7] who also found that it promotes not only healing of tuberculous ulcerations, but also absorption of infiltrations.

Another remedy, which has been tested by a number of colleagues, has been recommended by Simanowsky[8] and Spengler,[9] of St. Petersburg, viz., parachlorphenol. The former says that superficial nodules and ulcerations disappear quickly after a few applications, and that deeper ulcers and large infiltrations require treatment of several months. The solutions he employs are from five to twenty per cent. parachlorphenol in glycerin, and he claims that they exert their beneficial influence by penetrating into the depth of the tissues themselves. His views are corroborated by Spengler, Zinn,[10] Hedderich,[11] and others. Zinn praises the remedy very highly and considers it an important addition to our therapeutic means. It has also a long-lasting anæsthetic effect after the first pain from the application has subsided. In the discussion following Hedderich's paper, divergent views were brought forward by Lublinski and Seifert, who found the remedy too painful and of no better effect than creosote or chloride of zinc. From a limited experience I can testify to the efficiency of parachlorphenol, but in a few cases the infiltrations would not yield and I had to have recurrence to curettage.

In a paper read before the American Laryngologi-

cal Association at Washington, last May, Dr. Murray spoke of a new preparation, called enzymol, as a most valuable auxiliary to the curette and lactic acid. In his remarks he said that it was non-irritating, and possessed in a high degree the quality of digesting necrosed tissue. He applied it to a large ulcer upon the ventricular band, and in twenty-four hours the detritus with which the ulceration was covered had entirely disappeared, leaving a perfectly clean surface, upon the face of which were two nodular projections, apparently tuberculous deposits which had not yet undergone the process of ulceration.

The last part of our subject, the surgical treatment, is the most modern and radical measure, and consequently more a subject for criticism than are the previous ones. It comprises different procedures, viz.: 1, Incision; 2, curettage; 3, submucous injections; 4, electrolysis; 5, galvano-cautery; 6, laryngotomy; 7, laryngectomy; 8, tracheotomy; and 9, intubation. The endolaryngeal measures, and of these the curettage, are naturally of the greatest interest to us, and although with one exception—which will be stated later on—no important new discoveries have been reported, as far as my knowledge goes the number of opponents has lessened, the indications are more clearly defined, and a better judgment as to the results obtainable prevails.

Curettage, which was favorably spoken of by fifteen members of the laryngological section of the International Congress at Rome, has since made many converts, and it is a source of great pleasure for me to be able to say that it has also been more frequently employed in the United States within the last few years. Two years ago a general discussion on laryngeal tuberculosis took place at the meeting of the American Laryngological Association in May,[12] when the reader was assigned to speak about the surgical treatment; and later, in July, he was allowed to contribute his mite on the same subject before the British Laryngological Association,[13] after listening to the excellent essays of Krause and Heryng. From this time dates the greater familiarity of the American profession with surgical treatment, and although its adoption is but slowly progressing, I know, from personal and other communications with medical men and instrument makers who supply the instruments in increasing numbers, that curettage has taken a firm foothold also in the Western hemisphere.

The reasons why curettage is slow to find general recognition in suitable cases are in my opinion twofold: 1st, we are only too often confronted with the impossibility of eliminating the almost always concomitant pulmonary disease to which ultimately the majority of sufferers succumb; 2d, the difficulty of removing all the tissue which is diseased and of preventing relapses.

As to the first objection, the laryngologist is in the same position as the surgeon in similar cases. The latter does not hesitate now to excise a tuberculous articulation without hoping to cure thereby the tuberculous diathesis, but he removes by his operation a constantly threatening focus of infection. He makes gastrotomy in cancer of the pylorus without expecting to influence the malignant growth, but with the assurance that by the introduction of nourishment the tortures of starvation will be avoided and the patient's life prolonged. Operations with such an object in view are not only justifiable, but also imperative for the surgeon as well as for the laryngologist.

The second objection, as to the difficulty of removing all the diseased tissue, cannot be sustained if the cases are properly selected. It is true that we often labor under the disadvantage of not being able to excise the tuberculous infiltrations until we reach healthy tissue. But I believe that Pieniazek,[14] in his excellent monograph on laryngotomy, goes too far when he limits curettage, 1st, to cases in which there are no or only small infiltrations of the lungs; 2d, to those in which the laryngeal lesions are so circumscript that they can be easily and thoroughly removed, at the same time a part of the neighboring healthy tissue being taken away. We know that one curettage is seldom sufficient in a given case, and we should feel encouraged by the successful efforts of Hajeck,[15] who ultimately cured the larynx of a patient after having operated endolaryngeally twelve times before the granulations of the vocal cords and intra-arytenoid region were completely removed. In his paper he also emphasizes a point to which I attribute great importance, viz., to individualize and to discriminate in each particular case before curettage is decided upon. Some patients, he says, bear cocaine badly, lose their appetite; with others it is followed by fever and general depression. Rethi[16] is of the same opinion; he writes about a patient with a moderate infiltration of the intra-arytenoid fold and right vocal band, who became aphonic two days after curettage; severe dysphagia set in, the wound did not heal, and perichondritis developed with subsequent exitus. I had a similar case this spring, in which I considered curettage eminently in place, and in which it was also indicated on account of dysphagia. The excision of the intra-arytenoid region was easily accomplished, but the wound covered itself with a tenacious grayish deposit, which would not yield to local applications; the sufferings of the patient were increased rather than lessened, and his death was possibly accelerated by the well-meant operative interference. It is extremely doubtful if we shall ever be able to foretell in each individual case the accidents that may befall a patient whom we conscientiously believed a fit subject for curettage; but by following the indications to be stated we shall be guarded in the majority of cases against mishaps which may otherwise occur.

As to relapses, we shall not be able to forestall them by curettage, but, if it is rightly adopted and properly executed, they will not be more but rather less frequent than with other methods of treatment. We have at present no remedy which is an absolute safeguard against relapses in so treacherous and misleading a disease; but we are entitled to hope that the remedies which have promoted absorption of tuberculous infiltration so successfully without operative interference will also materially assist in the elimination of diseased tissue unavoidably left after curettage, as well as prevent too frequent relapses.

I crave your indulgence for the lengthy remarks just made, which contain nothing new to a body of men such as I have the honor to address. But curettage has more adversaries at large than we may perhaps believe, and I thought it only right that a positive declaration of its propriety and utility should be made on this occasion, which, with the discussion following, will have more weight and find more recognition than when made in a smaller circle.

Through the efforts of many of our best men, whose number is too large to permit naming them, the indications for curettage are now more clearly defined than they used to be. Theodor Heryng, your countryman, whom we can well call the father of surgical treatment, and who by his numerous publications and indefatigable efforts has probably contributed more than any of us to destroy the fallacy of the incurability of laryngeal tuberculosis, has in two recent publications[17] written fully about the indications and contraindications for curettage, the precaution we have to use in its execution, and the results we are entitled to expect. His views are the same as I expressed in my paper heretofore mentioned, with the only exception that I do approve of curettage as a measure for

relief in advanced phthisis, when the dysphagia is so severe as to prevent the patient from taking nourishment—a view which also Krause corroborated in his remark before the British Laryngological Association, 1895, giving at the same time a very good illustration of its benefit in a case of this nature. I therefore consider curettage indicated:

1. In cases of primary tuberculous affections without pulmonary complications, in one of which at least I prevented the infection from extending to the lower air passages and restored the patient to health after a severe and prolonged struggle, over eight years ago.[18]

2. In cases with circumscribed ulcerations and infiltrations of the larynx.

3. In cases with dense hard infiltrations of the arytenoid region of the posterior wall, also of the ventricular bands, tuberculous tumors of the epiglottis.

4. In the incipient stage of pulmonary disease with but little fever and no hectic symptoms.

5. In advanced pulmonary disease with distressing dysphagia resulting from infiltration of the arytenoids, as the quickest means of giving relief.

As the last indication noted may possibly incur more opposition than the others, I feel constrained to state that it was always a great source of satisfaction to me when I was able to relieve a sufferer, though I knew his days were numbered, from the tortures he had to endure. In such cases I know of no procedure which acts so rapidly and so effectually as curettage, and it is surprising how well such patients bear the operation and how quickly the wound heals, even in an advanced stage of the disease.

The contraindications for curettage are:

1. Advanced pulmonary disease and hectic.

2. Disseminated tuberculosis of the larynx.

3. Extensive infiltrations producing severe stenosis, when tracheotomy is indicated, or laryngotomy can be taken into consideration.

I fully agree with Heryng not to advise the operation in timid, distrustful patients lacking the necessary nerve power, and, like him, prefer to operate on the patient in a hospital, where he is under absolute control and the after-treatment can be carried out more satisfactorily.

The technique of the operation has been greatly facilitated by Heryng's rotary double curette, which, although published before the last international congress,[19] ought not to be left unmentioned in a treatise on this subject. Dr. Gougenheim constructed an instrument which he called "*emporte pièce*," which, being larger than Krause's curettes, enables him to remove a greater amount of tissue. The instrument is mentioned in his report at the last congress.

Two years ago, at London, Heryng spoke at length about the details of the technique of curettage, and showed elaborate drawings, which by his permission I present to the section. They are so well executed and so plain in their conception that I deem further remarks unnecessary.

Of the other surgical measures there are only a few about which I shall make some comment. Submucous injections of lactic acid gave me satisfactory results in a number of cases in which curettage was either objected to or considered inappropriate. Only two months ago I was spared, in all probability, a disagreeable experience by a submucous injection while preparing a patient for curettage. I intended to use the double curette and to excise both arytenoid regions, of which the right one was slightly ulcerated and felt softer to the touch of the cotton carrier when applying cocaine than the left one. As a number of applications did not produce the desired local anæsthesia, I injected cocaine with a laryngeal syringe into the right arytenoid swelling, when a continuous and prolonged hemorrhage followed. I naturally desisted from curettage, and injected in both sides a fifty-per-cent. solution of lactic acid. The result was that the hard dense left portion sloughed away almost completely after a week, leaving a healthy surface, and the right arytenoid meanwhile became smaller and firmer and allowed curettage without any untoward accident, greatly to the relief of the patient, who had not swallowed solid food for several weeks previously.

Dr. Chappell, of New York, has used the creosote treatment in his clinic during the last two years in the form of sprays, pigments, and submucous injections. For the latter he uses wintergreen and castor oil as a vehicle, in the proportion of one drachm of creosote to the ounce, which he injects with an automatic syringe devised by himself, and which I present for your inspection. His results are embodied in two reports,[20] which he supplemented by a verbal communication as follows: Of the first series of seven patients, four are alive; of the second series of thirty-two patients, eight are alive; including the four of the first series, ten had relapses, five died, and nine were lost sight of. Of twelve patients seen after publication of his reports, one had a considerable ulceration of the larynx which healed entirely, five showed marked improvement, of two he has no further information, and five lost the improvement previously gained. As I have not practised the local creosote treatment, I have no personal experience and must confine myself to reporting what has been communicated to me.

To the subject of electrolysis belongs cataphoresis, which I have to offer as a new contribution to the treatment of laryngeal tuberculosis, by Dr. Scheppegrell,[21] of New Orleans. Last May, after having tried several substances, he finally decided to use electrodes made of chemically pure copper, finding that the oxychloride of copper is a salt possessing marked germicidal properties, while exerting at the same time a stimulating effect on the pathological tissues. A five-per-cent. spray of cocaine is sufficient for local anæsthesia, the current must be weak (rarely over five milliamperes), and the copper electrode is to be connected with the positive pole, the negative pole with a large dispersing electrode to the neck. The applications are made, as a rule, every second day. To obviate laceration of the tissues during movements of the larynx and to prevent infections by punctures made by needles, he constructed spherical electrodes, which he found efficient for cataphoresis, and when properly applied to occasion no pain, irritation, or reaction. I brought the instruments with me, and offer them to you for inspection. Scheppegrell found autoscopy a valuable help when applying cataphoresis, and claims for the latter:

1. That there is no real destruction of the tissues or lacerations of the surfaces.

2. That there is absolutely no reaction, no hemorrhage.

3. That this method does not demand the high degree of skill required for curettage, and is especially simple when used with the autoscope.

4. That it is applicable in all cases of laryngeal tuberculosis.

Scheppegrell gave in his paper the history of three patients treated with cupric cataphoresis, to which he added four more cases in a letter to the writer, dated June 1st. All his patients had pulmonary complication. In three cases the treatment had to be discontinued on account of the advanced stage and weakness of the patient. In two recent cases the ulceration and infiltration of the arytenoid region subsided and the dysphagia was relieved. The first patient he treated was similarly affected, but after seven applications he was so much improved that he went into the country, from which he returned after six weeks with his pulmonary trouble aggravated, but with

no recurrence of laryngeal ulceration. His third patient suffered for seven months from tuberculous laryngitis, and had, in addition to ulceration and infiltration of the arytenoid region, also tumefaction of the epiglottis. After eleven applications the ulcerations had entirely healed, enabling the patient to take solid food without pain, and eight weeks later, with biweekly applications, the infiltrations also had disappeared. The improvement was lasting, and was verified six months later, when the larynx showed no return of the previous disease.

The number of cases is too limited and the time of observation too short to allow a definite opinion of the value of this method. But its application is simple and the results are sufficiently encouraging to merit further investigation and trial.

Larygotomy and tracheotomy in laryngeal tuberculosis have been the subject of two essays which deserve a passing notice. Crepon[22] has collected seventeen cases of laryngotomy from the literature, to which two have to be added, published by Lohoff,[23] and two performed by Pieniazek.[24] Four of Crepon's patients became worse after the operation; four were temporarily relieved from their sufferings but ultimately died from the pulmonary disease; seven experienced remarkable improvement of their ailment and also of their general condition; one patient, operated upon by Hopmann, was still able, after eleven years, to preach in a loud although somewhat hoarse voice. In one of the two cases reported by Lohoff the patient died immediately after the operation; the other, with infiltration of both lungs, was in fair health three years after the operation. Of Pieniazek's patients one died five days after, the other eighteen months after the operation. The latter considers laryngotomy indicated when the lesions are localized in the region of the glottis, therefore in affections of the vocal cords, of the arytenoid regions, and especially of the subglottic space. As he says that laryngotomy ought to be made only in a relatively good condition of the lungs, the number of suitable cases will naturally remain small, as we see unfortunately a well-developed pulmonary disease in the majority of our patients.

In his treatise on tracheotomy Lohoff does not consider it a curative measure, nor does he approve of it being made only as a last resource. He coincides with the generally accepted view that it is indicated in stenosis and dyspnœa, but in such cases without reference to the pulmonary condition.

If, in conclusion, we allow all that has been said to pass in review before our mind, we are compelled to acknowledge that during the last few years not only satisfactory progress in the treatment of laryngeal tuberculosis has been made, but also that in many directions diligent efforts are being made to overcome our deficiencies and to improve our methods. But let us at the same time keep in mind the well-meant words of Kuttner, viz., that by laryngotomy we can very well recognize laryngeal tuberculosis in its initial stage, but that we seldom see a patient at the commencement of the disease. When the necessity of an early interference shall be more fully accepted, when the better results obtained at this stage shall be more generally recognized, then also the laryngologist will find his task easier, and earn with greater satisfaction to himself the well-deserved rewards for his labors.

ON THE MICROSCOPICAL EXAMINATION OF BACTERIA, ETC.

By HENRY G. PIFFARD, M.D.,

PROFESSOR OF DERMATOLOGY, NEW YORK UNIVERSITY.

DURING a conversation recently held with one of our most eminent bacteriologists he expressed himself substantially as follows: "Bacterial investigation has about reached its limit. We may discover more species and doubtless will, but I do not see how we are to find out anything more about those known at present, unless some one will discover or invent new or improved methods of investigation."

In the systematic examination of bacteria as usually conducted at the present day, it must be admitted that the culture tube and the plate take precedence over the microscope. Prepare a slide in the ordinary way and submit it to a professed bacteriologist, and he will tell you at a glance through the microscope whether it is a coccus, a bacillus, a merista, a sarcina, or a —thrix. He will also tell if it is a streptococcus, or a staphylococcus, or a diplococcus, but beyond that he will hardly venture, except in the case of a limited number of micro-organisms with specially characteristic morphological peculiarities. If you press him for a diagnosis he will say: "Give me some of the fresh material and let me make plates and tubes, and I can

then tell you what it is;" and his diagnosis will be based more on the macroscopical appearance of the cultures than on the microscopical appearance of the organism. Occasionally differential staining and decolorizing methods will assist the observer in arriving at a decision as to the particular species under examination.

While the bacteriologists have exhibited the most persevering efforts in perfecting some of the details of their art, and great ingenuity in devising apparatus and other aids in their work, they appear in the main to have neglected one important side of the question —namely, the optical one.

The usual routine as practised in college and other public laboratories is to make the smear on the cover glass (sometimes wrongly on the slide), fix and stain it, and then examine the mount in water, cedar-oil, or balsam, using for the purpose a $\frac{1}{12}''$ homogeneous immersion objective and an Abbé condenser, with daylight illumination. If asked why they do not adopt better methods, some will reply that they did not know there was any better way. "This is the way the books tell you, and this is the way they do it in Germany." Others will say: "Oh, life's too short; haven't time to learn better methods, even if there are any. All I care about is to be able to tell a tubercle or some other bacillus when I see it, and I can do that now." Exceptionally there are men who would do better if they knew how, but whose lack of familiarity with the elementary principles underlying the microscopic art stands in their way.

To-day there are twenty-five men using the microscope where there was one twenty-five years ago, yet the average skill in microscopy possessed by the present-day workers is decidedly below that of their predecessors. That is to say, in former times there was a much larger proportion of workers who thoroughly understood the capacity and possibilities of the instrument than we find to-day. The mere fact that a man works six or eight hours daily with the microscope does not necessarily imply that he is a skilful microscopist, and when the work is of routine character and of limited scope it tends to retard rather than to advance the acquirement of special skill in the use of the instrument. A man may drive a garbage cart for ten years, going daily over the same route, but though he may be able to guide his horse through the street without collision or other accident there is little in his occupation that tends to make him a skilful horseman, in the proper acceptation of this term.

Before the invention of the homogeneous immersion lens, the value of wide angle and high aperture was fully appreciated by intelligent and observant workers, although the exact relationship of aperture to performance was not properly understood until made clear through the labors and researches of Abbé.

In the construction of dry lenses of wide angle, America twenty-five years ago stood in the van, with Charles A. Spencer as its leading exponent. On nearly a par with him were Robert Tolles and William Wales. In water-immersion lenses, England, represented by the firm of Powell & Lealand, was in the lead. The American makers were close seconds, and Hartnack in Paris stood next. The German objectives were but little esteemed, and at even the present day, so far as dry lenses are concerned, they do not compare favorably with the best American and English work.

Before the invention of the homogeneous immersion lens, workers with wide-angle dry and water-immersion objectives found it necessary to possess and employ a certain degree of skill in the management of their tools, and microscopy was truly an art requiring the exercise of the intellectual faculties as well as mere manual manipulation. The invention of the homogeneous or oil-immersion objective and the Abbé condenser have changed all this, and microscopy as generally practised at the present day is little more than a purely mechanical operation; and we need not therefore be surprised that there are large numbers of men using the instrument daily who have not the remotest conception of the true capacities of the instrument or of the proper means of developing them to the utmost. Place a high-grade dry lens (say, one of 4 or 3 mm. equivalent focus, and a numerical aperture above 0.90) in the hands of one of these men and he is absolutely helpless. He may by the veriest chance obtain a correct image of the object under examinations, but the probabilities of his doing so are very slight indeed.

Three or four years ago a gentleman who was an instructor in pathological histology in one of the laboratories of this city brought me a photomicrograph, saying that it did not suit him, but he did not know what the matter was. A glance at the picture revealed an intensely undercorrected image, and I told my friend that he had been using a very poor lens. "Why," said he, "that cannot be. I used a Zeiss 4 mm. apochromatic, and the object was carefully mounted with a very thin cover." I then asked: "What was the position of the screw collar?" He did not quite understand my question, but after some explanation admitted that he did not know what the adjustable collar was for, or how to use it, but that he always screwed it up tight and used it that way. In his ordinary work he always used the shortest possible tube length, as it didn't make him stretch his neck up so far to look into it, "except when I want to magnify a little more, and then I pull it out farther." There are just three ways in which one may obtain an undercorrected and untruthful image with a well-made high-grade dry lens. These are using too short a tube length, using too thin a cover glass, and bringing the middle and posterior systems of the objective into too close approximation.

Now in the particular instance here stated, the operator had succeeded in producing undercorrection in all three ways, and in fact had almost exhausted the possibilities in this direction in the falsification of the image.[1]

How many microscopical workers are there at the present day who take the pains to use cover glasses corresponding in thickness to the corrections of the objectives? How many adjust the tube length properly; and how many, if they happen to possess an adjustable objective, know how to use it?

Reverting to our first paragraph in reference to new and improved methods of investigation, we may well ask when will such methods be discovered? Possibly to-morrow—perhaps not for years. In the mean time would it not be well to utilize all means now known to science, whereby better images may be obtained than those now commonly displayed?

If we desire to accomplish this we must consider: (1) the illumination; (2) the condenser; (3) the objective; (4) the slide and cover; (5) the mounting medium; (6) the method of mounting and staining; (7) the immersion medium. To obtain the very best results the microscopical worker must avail himself of each and every aid that will contribute its factor toward the perfection of the image and consequent accuracy of delineation.

Illumination.—Before the invention of the Abbé condenser and at a time when achromatic condensers were few and far between, the concave mirror was the only available means of condensing the light on the object under examination. The curvature of the mirror was usually such that parallel light was focussed

[1] For further information concerning undercorrection, see MEDICAL RECORD, October 17, 1896, p. 545.

on the object, the mirror being permitted to move up and down on the bar, to allow for variations in the thickness of the slide on which an object was mounted. If daylight was used, the light reflected from a white cloud gave much finer results than light coming from a pure blue unclouded sky. The difference is so noticeable that some microscopists sought to imitate the cloud lighting by having mirrors made from plaster of Paris or porcelain, to be used with a blue sky. If artificial light is used, it is necessary to have either a mirror of shorter focus or to use a bull's eye between the lamp and the mirror; otherwise the light will be focussed considerably above the object and false diffraction lines may be more or less evident.

The Abbé condenser now in almost universal use is certainly an immense improvement over the simple mirror, and this with ordinary daylight constitutes the customary laboratory illumination. Good daylight, especially the white-cloud sort, leaves little to be desired for low and medium powers, but the variability of daylight on different days and at different hours of the day is a serious objection to its use with high powers, if we seek to obtain the best optical results. For the finest work one should discard daylight and the "Abbé," and use artificial light with an achromatic condenser. For ordinary work I know of nothing better or more convenient than an incandescent electric lamp with frosted bulb, giving a pure white yet soft light agreeable to the eye, and strongly imitating in its effects good white-cloud illumination. Gas and oil lamps of the Argand type of construction are extremely undesirable, as they give a large amount of diffuse light, accompanied at the same time by an uncomfortable degree of heat. The Welsbach and similar mantle lamps are still more objectionable. With lamps of this character it is not possible to obtain the finest resolutions of delicate structures, and all of them should be discarded as sources of illumination for the microscope. If kerosene oil is employed, the best lamp, especially for high-power work, is one with half-inch wick mounted in the focus of a bull's-eye lens, and with the narrow edge of the flame presented to the microscope. The lamp should be mounted so that it may be raised or lowered and tilted when necessary. Still better is the electric lamp with short straight filament, described by me some years ago.[1] With such lamps results can be obtained greatly superior to any possible with daylight. Acetylene gas, however, gives promise of proving an almost ideal source of illumination, and will doubtless come into extensive use as soon as a lamp is made with good mechanical features, and we can be reasonably sure that the lamp will not explode at some inopportune moment.

The character of the substage condenser is of the utmost importance. The chromatic or "Abbé" condenser is a cheap makeshift. It is certainly better than no condenser at all, and with daylight answers reasonably well. These condensers are made by every optician, and as they consist of either two or three simple crown-glass lenses there should be little difference in the products of the different factories. There is, however, a good deal of difference. The N. A. 1.20 and N. A. 1.40 of Zeiss are the best I have ever used. The N. A. 1.20 of Leitz is good, but I cannot say as much of the N. A. 1.40 of the same make.

A well-corrected achromatic condenser, however, is to be greatly preferred to an "Abbé." At least two of these should be at the command of the microscopist —that is, one of N. A. 1 for low and medium power work, and one of N. A. 1.30 or 1.40 for use with immersion lenses. The N. A. 1 achromatic will give a larger aplanatic cone of light than the N. A. 1.20 "Abbé," and is for this and other reasons to be preferred. The N. A. 1.30 or 1.40 achromatic will fill the most exacting demands of the best modern objectives. It should be understood, of course, that the apertures referred to exist only when the condenser is in oil-immersion contact with the lower surface on the slide. If used dry, the aperture is very much less and the results are not so good.

In bacteriological work the oil-immersion lens is almost universally employed, and one with a numerical aperture of 1.30 is perhaps the favorite. For purely clinical and diagnostic work an immersion lens is in most instances unnecessary, as the characteristic features of even the tubercle bacillus can be readily made out with a high-grade dry lens of one-eighth or one-tenth inch equivalent focus. No lens of the focus referred to with an N. A. lens less than .90 should be ranked as high grade, and should always be furnished in an adjustable mount. The greater the numerical aperture, the more sensitive is the lens to cover-glass thickness. Lenses of this description are not in very common use, and for two reasons. In the first place they are expensive, and secondly the great majority of microscopical workers do not know how to correct a lens for cover-glass thickness and will not take the trouble to learn. If they happen to possess an adjustable lens they use it with covers of varying thickness, at perhaps either the open or closed point; are dissatisfied with the result, and continue their work with the cheap but inferior German lenses.

Bausch & Lomb make an excellent dry $\frac{1}{6}''$ adjustable objective with an aperture of .92. The price seems very high in comparison with a Leitz of the same focus with an aperture of .85. Those who count the cost will buy the latter, while those who desire a distinctly superior performance and possess the skill to manipulate the lens, will doubtless prefer the former. With such a lens nine-tenths of routine bacteriological work can be done in a very satisfactory manner. It should be remembered, however, that with the high aperture of this lens the working-distance is necessarily small. Bacteriological mounts may be made on covers not exceeding .17 mm., but for histological sections thinner covers should be used. The objective referred to is corrected for a tube length of 216 mm., which is a desirable mean between the inconveniently long English (250 mm.) and the unnecessarily short German (Leitz, 170 mm.; Zeiss, 160 mm.) tubes.

For research work immersion lenses of the highest possible aperture should be employed. Zeiss, and Powell & Lealand offer objectives of N. A. 1.40, but in both of these instances the front lens is not very securely fastened in the mount. Bausch & Lomb and Spencer quote lenses with N. A. 1.42, and repeated measurements have shown me that the claimed aperture is fully realized, and I have never known of the displacement of the front lens in either of these makes. Powell & Lealand also construct an oil-immersion objective with an aperture of 1.50, and Zeiss a monobromide immersion with an aperture of 1.63, but this latter requires special flint-glass slides and cover glasses, which are expensive, costing two marks apiece for the slides and one mark for the covers. Some adjustable oil immersions will also work with monobromide, giving thereby increased aperture and improved performance.

Slides and covers to be used in connection with bacteriological technique should be the same that I have elsewhere[1] recommended for use in the examination of blood.

The medium usually employed for permanent mounts is Canada balsam, while for mere temporary examinations water and cedar (immersion) oil are frequently made use of.

[1] New York Medical Journal, July 16, 1892; Medical Record, May 4, 1895.

[1] Medical Record, October 17, 1896.

When deeply stained, bacteria may be regarded as opaque bodies and consequently without refractive index, and their form becomes manifest through contrast with the refractive medium that surrounds them, be the same air, water, oil, or what not. Now in a general way the greater this contrast the more distinctly the morphology of the micro-organism is displayed. Water has an index of 1.33, while cedar oil and the xylol and benzol solutions of balsam have an index of about 1.52. Consequently the visibility of bacteria in either of these latter is greater than in water. The oil of cinnamon (cassia), however, has an index of 1.59 and is consequently better than either of the media mentioned. "Naphthalin-ambar"[1] with an index of 1.625 gives us ten points' gain over balsam and is well suited for permanent mounts, while the pure monobromide of naphthalin (index 1.65) displays them still more finely. Mounts may also be made with a medium of still higher refractive index, namely, the iodide of methyl (n=1.72). There are two inconveniences connected with the use of this substance. In the first place it is extremely volatile and the cover must be instantly sealed to the slide, best done with Bell's cement; and, secondly, it rapidly extracts some of the basic stains from the bacteria and diffuses them through the medium.

It must not be supposed, however, that the media of high index are alone useful in the examination of bacteria, as many peculiarities and points of structure are more readily seen in media of comparatively low index, like water (n=1.33). For instance, take a living and sporulating culture of anthrax and prepare a cover film in the usual way, fix by heat, stain if you please with fuchsin, and mount in balsam or some similar medium; then make another mount in water or serum without fixation or stain, and compare the two. In the latter case we are enabled to see the bacteria in nearly or quite the condition that they exist in nature, but in the fixed and stained preparation we look only on thin shrivelled corpses. We think the microscopist would hardly seek to solve problems in human biology by the study of the tissues of an Egyptian mummy, and yet this is practically what they are doing when they confine these studies to the dried and stained bacterial filaments. My own studies in the realm of bacteriology have been too limited to permit me to dogmatize on this subject, but researches in a closely allied field among the moulds and other fungi, and the lower chlorophyllous algæ, desmids, and living diatoms have demonstrated the advantages to be derived from the study of these organisms under conditions of least possible morphological distortion. For instance, make a cover-glass preparation of the common Oidium lactis, dry, fix by heat, stain, and mount in a balsamic medium. Prepare another cover glass, and without drying, fixing, or staining mount immediately in glycerin jelly, or a ten-per-cent. solution of lysol. Examine both mounts with a good objective and note the remarkable difference in the appearance. The spores of lycopodium mounted in one medium show the surface reticulations distinctly, while the interior is translucent and apparently structureless. In another medium the reticulations may be invisible, while the interior contents (oil globules, etc.) constitute the prominent features of the picture. Take a little starch of almost any sort and mount in balsam, and compare it with some mounted in glycerin jelly or lysol solution. Do the same with the spores of some of the hymenomycetes. In the balsam mounts one will find very little clew to the intimate structure of these several bodies, while the other mounts will exhibit details invisible in the former. Why, then, should not these various methods find a wider application in bacteriology than now appears to be the case?

If then bacteriology, as suggested, has nearly reached the end of its tether with its customary methods, would it not be well for the students of this branch to avail themselves of methods found useful in other departments of natural science, and especially develop their microscopical technique to the utmost?

256 West Fifty-Seventh Street.

[1] The preparation of this was described by me in this Journal, May 4, 1895. It may be obtained ready for use from Eimer & Amend, of this city, or the purified gum may be had from Paul Rousseau & Cie, 17 Rue Soufflot, Paris. The gum thus obtained should be mixed with the requisite amount of monobromide of naphthalin, so that the resulting solution shall have the required index.

"IN THOSE DAYS THERE WERE DEVILS."[1]

By James Weir, Jr., M.D.,
owensboro, ky.

There are many a romance and thrilling tale hidden amid the dusty tomes of mediæval medicine. Especially is this true of those old works which treat of demoniacal possession and obsession, of trance, ecstasy, and the thousand and one manifestations of hysteria then characterized as visible presentments of the devil himself *in propria persona*. In the tale of Urban Grandier, in "Crimes Célèbres," Alexander Dumas has simply related an historical episode, confining himself closely to absolute fact. Laigue-Gentil gives the medical points of this strange story, and from these two authors the following paraphrase is derived.

Even in early youth Urban Grandier was distinguished by a mental acuteness and activity that far transcended the mediocre and groping psychical efforts of his companions. The boy's high intellectuality soon attracted the notice of his uncle, Claude Grandier, a scientist of considerable note in his day, who undertook his early education. After several years' study with his uncle, Urban was enrolled at the age of twelve in the Jesuits' College at Bordeaux. His teachers soon discovered marked oratorical talent in the youthful student, whereupon he was made to preach and declaim, his style being carefully watched, criticised, and corrected. As soon as he arrived at a suitable age the college authorities made him curate of St. Peter's Church in the town of Loudun; soon after this he was given the stipend of a prebendary in the college of Sainte-Croix. Contemporaneous writers describe him as being about thirty years old (1631), "tall and well proportioned, his air noble, and his countenance very handsome, although its expression was a little haughty." He was by far the most learned man in that section of the country, a finished orator, a courtly, refined, and agreeable gentleman. He was free from all the vices of that age, and the only fault that could be found in him by his enemies (and he soon made a host of very formidable and powerful ones) was an inordinate fondness for the society of women.

By his wit, his learning, his oratory, and his pleasing personality, he soon filled his church to overflowing with zealous and admiring communicants. But, just in proportion as St. Peter's became crowded, the congregations of the other churches and the perquisites of the priests in charge of them dwindled away. This, of course, aroused jealousy, and jealousy soon turned into downright, deadly hatred.

Urban was gentle, affable, agreeable, and affectionate when among his friends, but when among his enemies, especially when he had right on his side, he was

[1] The notes for this paraphrase of Dumas' story were made and the MS. was partly written in the winter of 1889; it was not completed, however, until the summer of 1896. Recently a translation of "Crimes Célèbres" has appeared, in which the story is told in full. This paper was sent to the Medical Record during the summer of 1896.

stern, haughty, and absolutely inflexible. Soon after he was given the prebend in the college of Sainte-Croix, he sued that chapter for the possession of a house and won his suit. He immediately pressed the judgment given him in this suit to a fulfilment, thereby incurring the bitter enmity of Mignon, a canon of Sainte Croix and director of the Ursuline convent. This priest was an arrant hypocrite, a detestable liar and falsifier, and was, as we shall soon see, the head and centre of the miserable band of plotting priests, nuns, officials, and riffraff that brought the brave and honorable Grandier to a horrible torture and to a still more horrible and painful death.

About the time of Urban's victory over the chapter of Sainte-Croix, Julia Trinquant, the beautiful daughter of the *procureur du roi*, fell sick with some lingering disease, and Martha Pelletier, one of her girl friends, left her own home and went to that of Julia in order to nurse her sick friend. During the course of Mlle. Trinquant's illness, a child was born to Mlle. Pelletier, but the people of the town, influenced by the atrocious calumniator, Mignon, ascribed maternity not to Martha, the real mother of the child, but to Julia, the fair and innocent daughter of the *procureur du roi*. The father of the child was declared to be Urban Grandier. Trinquant, by virtue of his office, had Martha arrested; she was brought before him and questioned, but she swore over and over again that the child was her own. She also declared that Urban Grandier was not the father of her child. The public was not convinced, however, but still believed that Mlle. Pelletier had assumed the guilt of Mlle. Trinquant for a monetary consideration, and that Urban was the father of the child.

M. Barot, a rich and influential citizen of Loudun, and Mignon's uncle, had had a furious quarrel with Grandier, in which he came out badly worsted. This made him an implacable foe, and one, too, on account of his wealth and position, to be feared. This man invited Trinquant, Mignon, and a priest named Meunier (from whom Urban had won a lawsuit) to meet him and to join him in a cabal against their mutual enemy; M. Menuau, *avocat du roi*, who was jealous of Grandier, also came to this meeting. Having failed to incriminate Urban and Julia Trinquant through Martha Pelletier, they set themselves to evolve another plot. But Father Grandier lived so honestly and uprightly that they could find no fault on which to base an accusation.

I have stated above that he was exceedingly fond of female society, though, as we have now every reason for believing, this penchant was entirely innocent. His enemies, however, started the report that he was conducting a *liaison* with a young lady of Loudun, and that in order to overcome her scruples he had married her, having performed the double office of priest and husband. Such was the silly tale inaugurated by this unscrupulous cabal, and which, as they thought, would bring their haughty enemy to terms. But Grandier, secure in his innocence, treated their accusations with contemptuous indifference. Upon a certain occasion, however, his anger got the better of his pride, and he bitterly reproached one Duthibaut, who had persistently circulated the story of his marriage with the young lady. This man, stung by and writhing beneath the smart of Urban's matchless invective, raised his cane and struck him. This scene occurred in the Church of Sainte-Croix while the priest was still dressed in the holy robes of his office, constituting, necessarily, a sacrilege of the gravest moment. Urban proceeded against Duthibaut, who, by the way, was rich and influential, with his usual promptness. He complained to the king, Louis XIII., who at once brought the matter before parliament.

While Urban was in Paris prosecuting Duthibaut for sacrilege, the cabal in Loudun was busily preparing a bomb in the shape of an accusation that was to be placed in the hands of his superior, the bishop of Poitiers. Two men were found who, for money, swore that he had debauched women and girls, and that he had converted St. Peter's Church into a *maison de joie*, and that he never read his breviary. The bishop, who was Grandier's enemy also (the latter having granted a dispensation of marriage, which was a prerogative of the former, hence his enmity), issued a writ of arrest and summons for Urban to appear before him. The summons, with a copy of the accusation was given to Duthibaut, who hurried to Paris and placed them before parliament. This body then decided that the priest must stand his trial before his religious superior before they could proceed further with the case against Duthibaut. Grandier's high courage did not desert him; he travelled back to Loudun with all speed. As soon, however, as he arrived there and before he could make any efforts toward preparing his defence, he was seized and thrown into one of the noisome dungeons of the bishop's prison. Here he remained closely confined for two months. He was then brought out for trial, and, notwithstanding the fact that the charges were mere assertions as in the case of the young lady to whom he was reported to be already married, no names were given to the women and girls whom he was accused of debauching), he was found guilty and sentenced to live on bread and water for three months, and debarred the practice of his priestly functions in the diocese of Poitiers for five years, and in Loudun forever. Grandier appealed from this sentence to the archbishop of Bordeaux; his accusers, thinking completely to annihilate him, then also appealed, carrying their appeal to parliament. It was decided, however, that, owing to the great expense incident to the transportation and maintenance of so many witnesses, the case should be tried by the civil court of Poitiers. In this just and impartial court the false witnesses were soon entrapped into making contradictory statements, whereupon they lost courage and confessed that their evidence against Urban was false. He was consequently, on May 25, 1631, declared not guilty by the court. He had yet to stand his trial before the archbishop of Bordeaux, who was then at Saint-Jouin-de-Marmes. He hurried thither and asked for an immediate trial, which was granted, and, in a few days he returned to Loudun in triumph—he had been acquitted on every count of the indictment.

We may take it for granted that a man of Grandier's temperament did not let matters rest here—nor did he. He at once entered proceedings against Mignon, Trinquant, Barot, Meunier, and Menuau for conspiracy. Meanwhile he had vigorously conducted the prosecution of Duthibaut (the man who had struck him with a cane in the Church of Sainte-Croix), and had gotten a judgment against him. Duthibaut was fined, reprimanded, and forced to pay a sum of money to the priest whom he had insulted. The cabal found themselves in hard case—from accusers they had become the accused, from prosecutors they had become the prosecuted. It behooved them to bestir themselves and crush their enemy, otherwise they were lost. They met again, Duthibaut having been added to their number, this time at a house belonging to Trinquant in the village of Pindardine; there they formed a new plot which, for utter wickedness, is without parallel in the history of mankind.

Some time before the events just related had transpired, the mother superior of the Ursuline convent had asked Grandier to become the spiritual director of her household. He, owing to his multitudinous engagements, had refused, thereby incurring the enmity of the nuns, who considered themselves scorned and despised. Better had it been for him had he

thrust his right hand into fire and burned it to a cinder than to have used it in penning a refusal to these women! For, by these weak women and girls was he to be dragged down and utterly destroyed.

Several days after the meeting of the conspirators at the house of Trinquant in the village of Pindardine, it was whispered in Loudun that two nuns in the Ursuline convent had been possessed by devils, and that these devils had been enabled to penetrate into the bodies of these holy women solely through the magic of Urban Grandier, a priest of Holy Mother Church. "Horrible! a priest and trafficking with devils. Send for the executioner! Send for the stake! Burn him! burn him!" Thus the superstitious and the ignorant. Fortunately for Urban, as well as for us, even in those days there were some people who did not believe in diabolical possession, and the seneschal of the town of Loudun was one of those people. Mignon, who had been appointed spiritual director of the convent after Grandier's refusal, sent for the curate of Saint-Jacques of Chinon, Father Barré, whom he desired to assist him in exorcising the devils. The seneschal of the district, Guillaume Cerisay de la Gueriniere, and the civil lieutenant, Louis Chauvat, requested that they might be present at the exorcism. When the two officers of the law arrived at the convent they were met by Mignon, who told them a wonderful tale of spectres, goblins, and devils. He informed them that the two possessed nuns were asleep, but that if they would come back at some future time they could see these wonderful performances and judge for themselves. Here I will quote from Dumas' "Celebrated Crimes" the following passage: "The two magistrates were taking their leave, when a nun hastily announced to them that the two possessed sisters were again tormented by their persecutors; they went up with Mignon and the curate of Venier into a room at the top of the house, furnished with seven small beds, only two of which were occupied, the one by the abbess and the other by the lay sister. . . . The two magistrates had no sooner entered the room than the abbess was seized with violent convulsions, making the strangest contortions, and uttering cries in exact imitation of those of a sucking pig." . . . Mignon told the seneschal and the civil lieutenant that the abbess herself did not understand Latin, but that the devil inhabiting was a good classical scholar and spoke good Latin; he would, therefore, interrogate her in that language. After exorcising her he began the interrogation.

Q. "*Propter quam causam ingressus es in corpus hujus virginis?*" (Why have you entered the body of this young maiden?)

A. "*Causa animositatis.*" (On account of enmity.)

Q. "*Per quod pactum?*" (By what compact?)

A. "*Per flores.*" (Flowers.)

Q. "*Quales?*" (What flowers?)

A. "*Rosas.*" (Roses.)

Q. "*Quis misit?*" (Who sent you?)

At this question the two magistrates observed the movement of hesitation in the abbess; twice she opened her mouth to answer, without uttering a sound; the third time she replied in a faint voice:

A. "*Urbanus.*" (Urban.)

Q. "*Dic cognomen?*" (What is his surname?)

Here, again, the possessed woman appeared in a state of hesitation, but, as if compelled by the power of the exorcist, she answered:

A. "*Grandier.*" (Grandier.)

Q. "*Dic qualitatem?*" (What is his profession?)

A. "*Sacerdos.*" (A priest.)

Q. "*Cujus ecclesiæ?*" (Of what church?)

A. "*Sancti Petri.*" (Of Saint Peter.)

Q. "*Quæ persona attulit flores?*" (What person has brought the flowers?)

A. "*Diabolica.*" (A person sent by the devil.)

In this interrogation the devil used correct Latin, for he had been well drilled; we will see, however, that in another interrogation he used Latin bad enough to have shamed a ten years' old seminarian. These exorcisms and interrogatories continued at intervals for several weeks, when it was announced by Barré, and confirmed by the abbess, that instead of one devil there were no less than seven in her body. These devils were named Asmodeus, Béhérit, Cerberus, Earas, Elimi, etc.

It is not to be supposed that Grandier was in ignorance of these performances; he was fully aware of his danger, and felt alarmed for the first time in all his life. He remembered Ganfredi, who had been executed only a few years before for dealing in sorcery and witchcraft. The seneschal was an upright, honorable man, and felt convinced all along that there was a conspiracy between nuns and priests for the overthrow of Urban. To him, then, this unfortunate man appealed; he demanded that the two nuns be separated, and that other exorcists and physicians be appointed. This the seneschal endeavored to do, but, much to his surprise, was even himself refused admittance to the convent. Grandier appealed to the archbishop of Bordeaux, who at once appointed a commission, composed of Sieur Barré, Father l'Escaye, and Father Gau, men in whom he had the utmost confidence. As soon as this commission took charge of the possessed women, the devils left them and did not return while they remained at the convent. The archbishop had previously sent his own physician to examine the nuns; the devils had remained quiet during his visit, and so he had nothing to report. But fate, in the shape of Cardinal Richelieu, far away in Paris, was reaching out eager hands toward the unfortunate Grandier. M. Laubordement was sent by Richelieu to Loudun with orders to demolish its castle. This man was introduced to Mignon, Trinquant, Barré, and others of the cabal, who became quite intimate with him. The commission of the archbishop of Bordeaux having been withdrawn about this time, the devils returned in full force. M. Laubordement was present at the exorcisms (for as soon as one devil was compelled to take his departure another devil took his place) and was apparently fully convinced of the genuine character of the manifestations. But this man had joined the conspirators, for he was a relative of the abbess and was deeply incensed at the archbishop's action in appointing a commission to judge as to the genuineness of the diabolical phenomena.

He returned to Paris and sought the all-powerful duke. No sooner had Richelieu heard the name of Urban Grandier and the charges against him, than he smiled in grim satisfaction. When the cardinal was prior of Coussay he had had a quarrel with Urban and had been badly worsted; here, then, was his enemy betrayed into his hands. A writ for Grandier's arrest was at once made out and signed by the king; this was given to Laubordement, who returned at once to Loudun, where his unfortunate victim was arrested and thrown into prison. The exorcisms and interrogations and diabolical manifestations continued; a host of devils descended one night, and the next morning eleven more young girls, inmates of the convent, were howling and whooping like demons. Asmodeus and Cerberus and Béhérit and Earas and the remainder of the seven devils, however, still continued faithful to their first love, the abbess, Jeanne de Belfield. Their Latin became incorrect, however, just as soon as the interrogations became frequent and lengthy. One more quotation to prove this:

"Mass being concluded, Barré approached her to offer her the communion and to exorcise her; and,

holding the holy sacrament in his hand, he said to her:

"'*Adora Deum tuum, creatorem tuum.*' (Adore your God, your Creator.)

The abbess remained silent for a brief space, as if she found much difficulty in expressing this declaration of love: at last she said:

"'*Adoro te.*' (I adore thee.)

"'*Quam adoras?*' (Whom do you adore?)

"'*Jesus Christus*' (Jesus Christ), replied the nun, who was not aware that the verb *adoro* governs the accusative case. . . . Daniel Douin, the assessor of the provostship, could not refrain from saying aloud: 'Here have we a devil who is not strong in the verbs active.'"

This miserable chicanery was kept up for months, the unfortunate Grandier fighting against it as well as he could from the depths of his dungeon. The seneschal, and his brother magistrates also, did what they could. Time and again did they expose the shallow artifices and subterfuges of Mignon and Father Lactance (another priest who had joined the conspirators) but all in vain—the case had been prejudged, the sentence had already been formulated. Even when Sister Claire, weeping in bitter sorrow at the part she had played in bringing a good man to his death, confessed to Father Lactance before a crowded church that she had given false evidence and that she had feigned diabolical possession, the priest only laughed in her face, and cried out that it was the devil speaking and not the good sister. She was hurried back to the convent, never again to emerge therefrom. "A still stranger scene took place upon the day after. While M. Laubordement was questioning a nun, the superior came down into the court with naked feet, and a rope round her neck, in the midst of a frightful storm," and stood waiting for him. When he appeared, "Sister Jeanne des Anges (Jeanne de Belfield, the abbess), kneeling down before him, declared that she had not power to play the horrible part which had been taught her any longer, and before God and man she declared Urban Grandier innocent." M. Laubordement, like Father Lactance, only laughed, and said that it was the devil speaking with her tongue. Sisters Jeanne and Claire were the nuns first corrupted by Mignon and his ally, who, together with the other conspirators, were the only visible and real devils in this infamous drama of crime. After a farcical trial, Grandier was condemned to the torture of the boot, and finally to be burned alive in the "public place of Sainte-Croix." On the 18th of August, 1634, he was taken to the torture chamber by Laubordement and Father Lactance. The executioner was dismissed, and then these two gentle followers of the merciful Christ proceeded with their own hands to apply the boot to their victim's legs and to crush them into a bloody, formless mass of bone, flesh, nerve, and ligament. After some further torture, during which they continually commanded Urban to confess (he replying that he was innocent and could not imperil the safety of his soul by the utterance of a lie in order to save his body from torture), they placed him on a cart and hauled him to the public place of Sainte-Croix. He, being unable to stand on account of his crushed limbs, was then fastened to the stake with a chain, which was passed around his middle. The fagots were fired, and, after calling aloud the name of Jesus three times, amid flame and smoke the spirit of this good priest left its earthly tenement and ascended to its Maker. Thus died Urban Grandier, the victim of one of the foulest plots that ever disgraced humanity. That it was a plot, the testimony of the abbess and Sister Claire most positively declares and affirms. Verily, there *were* devils in those days.

"WAVELAND."

THE HAND AS A PROPAGATOR OF MICROBIC DISEASE — A MEDICO-SOCIAL QUESTION.

BY NATHAN BREITER, M.D.,

NEW YORK,

VISITING PHYSICIAN TO THE HEBREW CHARITABLE DISPENSARY.

A FEW weeks ago I happened to meet a chance acquaintance, and, of course, the usual mode of greeting manifested by the shake of the hand was resorted to. I at once perceived something rough and oily about his hand, but, not wishing to discuss the matter, I said nothing relative thereto, and the circumstance very soon faded from my mind. A few days subsequent to that time the same person presented himself as a patient at my office, and, forgetting my former impression, he shook hands again, whereupon I noticed the same condition as before. An examination revealed the fact that he had had a hard chancre about six months prior to his call, and that at the time of his call he was suffering from an extensive syphilide which partly involved the hands. On the discovery of this fact it at once occurred to me that I had not washed my hands until several hours had elapsed after our former friendly greeting. I felt like shaking my hand off or shaking the custom out of existence. An effort in the latter direction seemed more feasible. I studied the question—the medico-social question—its cause, effects, and treatment.

Cause.—In view of the fact that most of the customs have had a somewhat similar origin, some more, others less rational, most began in the impulsiveness occasioned by circumstances, varying as to time and place, and founded in extensiveness on mimicry, a consideration of the one seemingly most grave at the present time will also reflect upon and give credence to others still extant.

In Leopold Wagner's "Manners, Customs, and Observances," we find the following: "The custom of shaking hands originated in the ancient and universal practice of grasping the weapon hand during a truce as a precaution against treachery. But it will be asked, how came it that the chance meeting of friends was signalized by a shaking of hands? To this it may be answered that, just as the warrior clutches the weapon hand to prevent mischief, so he freely extends his own weapon hand to a friend as a sign that he has no thought of standing on the defensive." He also states that the exertion caused by this very vigorous grasp caused the hand to shake. Now, here we certainly have a rational condition of things born of necessity and practised intelligibly. As time rolled on, necessity became a negative factor; the spirit which actuated the original grasp gone, the vigorous symbolification became less marked, and soon the natural shake which was consequent upon enervation was substituted by the artificial one consequent upon device. But still the practice continued, modified here and there by the whims of successive generations, mostly performed with indifference, occasionally with some degree of pleasure, in no case with any apparent detriment. And so, by continuous application a feeling was engendered, cultivated, and propagated to posterity, becoming a habit akin to a natural law. So we see that from a comparatively dark and illiterate period a custom having a rational origin, which *rationale* dwindled into nothingness during its spread and migration through successive centuries, was ushered into our glorious civilization, unnecessary in it essence, devoid of all intelligence, and positively injurious to public health. Unconsciousness is blameless in inactivity. The microscope and bacteriology have opened our eyes. Now torpidity where danger lurks becomes a crime.

Effects.—I have in a very limited way resorted to a

series of experiments relative to the bacteriological condition of the skin of the hand, but as my results are but shadows of already established facts, and as the purpose of this paper is only to expound the disastrous relationship between known contagious and infectious diseases and a social custom, I shall at once proceed with my delineation of effects.

Prof. W. H. Welch, in his article on "General Bacteriology of Surgical Infections," in Dennis' "System of Surgery," says: "As the skin is exposed to contamination from the air and all sorts of sources, it is evident that there is scarcely any limit to the number of species of bacteria which may possibly be found on the skin." Also "the kind and the number of bacteria found upon exposed parts of the skin vary considerably according to the habits and the occupation of the individual." That the surface of the human body is a very hotbed for the propagation of a great variety of micro-organisms, Fürbinger, Mittman, Bizzozero, Maggiora, Welch, and many others have elucidated most conclusively. It is certainly beyond the shadow of a doubt that in the presence of a predisposing factor, and sometimes even without, the microbic diseases are ushered into existence by their individual prototypes, this being essentially brought about by contact in some way of the two contingent forces. Modern surgery is founded on this principle. The carefulness with which we prepare our hands and surgical instruments before and after a surgical operation well exemplifies the importance of a familiarity with its dangers in every sense. We recognize the fact that many of our microbic diseases, especially those of the exanthematic type, eliminate their toxic element very largely through the medium of the skin, which undergoes extensive exfoliation disseminating the poison far and wide. These conditions are recognized. Isolation is resorted to and enforced most rigorously, thereby checking the spread of the disease, and then disinfectants, lavishly applied, cause the destruction of the offending armies. In the era of scientific prophylaxis consequent upon the introduction of the microscope, bacteriology, and antiseptics, we find a steady decline of epidemics either developing in the outer world or in our hospital wards. The aphorism, "An ounce of prevention is better than a pound of cure," is well exemplified in every department of medicine. Yet, accidental inoculations of tuberculosis, syphilis, small-pox or vaccinia, and the like, still exist, and are but demonstrations of either an unavoidable cause—which, by the way, divests it of its purely accidental origin—or a faulty observance of established data. Medical literature is by no means devoid of classical descriptions of microbic disease consequent upon ritual observances. However, as far as such customs (and they are in a sense customs) are concerned, aside from using the modern methods of surgical cleanliness, little if anything can be done. They are deep rooted. Martyrs to religion have come and gone. Martyrs still exist, and martyrs are still to come. Many changes as to wearing-apparel, so far as they affect our physical well being, have been brought about by medical agitation. It may be difficult in the beginning for the general public to conceive the cause, but it does gradually fall in line, whether through actual conception or mimicry makes no difference; it follows, and because it follows it should be properly led.

The corset, with it barbaric origin of metal breastplate, has gone through its evolutionary stages, doing its systematic harm and furnishing material for the contention of the gynæcologist; and because of this contention, in lieu of its eradication, it has met with improvements so as best to conform with woman's physical well-being. I say "woman's" because society is so constituted as to make woman's appearance a factor—and that largely—in her entire makeup. One more instance: During the early part of the tenth century the barbaric custom of wearing earrings was discarded, to be brought to light again in the time of Queen Elizabeth. Prince Henry III., of France, being of effeminate nature and anxious to ape the opposite sex, adorned his already girlish person with precious ornaments dangling from his ears. His courtiers and chevaliers followed; the public followed. It became a general custom almost throughout the civilized world. Our immortal Shakespeare was not insensible to the remnant (ear strings) of this new device. But, fortunately, perhaps through man's superior strength, this superstructure, founded upon imbecility, met with a speedy dissolution. It remains for the weaker sex to follow. Instances of infectious skin diseases or infectious constitutional diseases of the most grave nature are not unheard of consequences of this absurd custom. They may not be proportionally large in number, but they are real, and such reality, however small, with an avoidable cause, must, of necessity, be a reproach to our boasted civilization.

Now what can we say of the hand—the subject proper of this paper? The hand, in order to serve the manifold purposes of its existence, is forced to contend with circumstances which, by no means, add either to its cleanliness or to its freedom from courting disease. The importance of this essentially mournful condition has manifested itself in many instances in a very palpable and painful way. Diseases most dreadful in their nature and origin have forced themselves upon us, giving us the stigma of malefaction and our progeny the heritage of shame. The introspective and practical mind will readily conceive the revulsiveness of feeling engendered in our friends and acquaintances when deteriorating conditions, avoidable or unavoidable, associate themselves with our well being. Society attempts to shut the gates upon us, physicians clamor for social ostracism, and both with justice. Should any stone be left unturned in our endeavor to give ourselves and posterity the best possible phase of a future existence?

In my limited series of experiments I have found—as more accurate observers have before me—among patients with gonorrhœal urethritis that the filth collected from the surface of the hand showed the presence of the gonococcus of Neisser; among tuberculous cases the presence of tubercle bacilli; among diphtheria cases suspicious Klebs-Loeffler bacilli; and, doubtless, every disease of a microbic nature has an infinite number of its treacherous and devouring prototypes in this cordial member of greeting, ready to attack the new and unsuspecting. The presence of most of the known types of bacteria have been found upon the normal hand as well, and it requires no great stretch of the imagination reasonably to conclude that these micro-organisms can be present. The clinical demonstration supporting these conditions is as old as the knowledge of the causative relation between microbe and disease. Instances of auto-infection, both of the original and reinfection kind, are within the experience of every physician. The large number of cases of infectious and gonorrhœal conjunctivitis with or without gonorrhœal urethritis, tuberculosis—local or general—infectious skin diseases, primary syphilis, erysipelas, sepses of any kind, or any of the transmissible diseases includes with its causative relations, as a factor, the hand. Medical literature is not lacking in evidence of this fact. Frequent ablutions may moderate the extent of but do not eradicate the evil. In this connection I may here state that an incident which occurred to me a few weeks ago struck the mark most forcibly. Two male friends consulted me about their respective troubles. One had a typical gonorrhœal urethritis, the other a typical gonorrhœal conjunctivitis without apparent cause. The gonococcus

of Neisser was found in both cases. No interchange of towels had taken place. The only contact between them was the customary handshake on meeting and parting. In the absence of a more probable cause for the conjunctivitis the hand is certainly a plausible one. I recall another instance which occurred with me about six years ago, while practising medicine in the city of Chicago. A friend of mine, with whom I had been in the habit of shaking hands, consulted me about a "pimple," as he called it, on his right index finger. I suspected nothing out of the ordinary and paid little attention to it. The pimple persisted in its sluggish existence and soon assumed a suspicious aspect. I then questioned him closely, and found that he had been indulging in digital exploration of a female's genital organs. Secondary symptoms later on confirmed the suspicion; yet this man certainly exercised no compunction in extending in friendly greeting his filthy member. Many victims of scarlet fever, both in the early and desquamative stages, especially the latter, are walking the streets of every large city ready to engraft upon the moist hand of any chance acquaintance the prolific virus of the disease. The same may be said of persons with pulmonary tuberculosis, whose hands and handkerchiefs, through incessant wiping of the mouth, are foul and saturated with the bacteria-laden expectoration of the disease. A skin specialist of large experience tells me that he has seen among laymen many cases of primary syphilis of the hand, without any recognized source of infection. Also that he has had cases coming to him with the secondary roseola eruption which he traced to an untreated small and sluggish ulcer on the hand, these patients having been unaware of the nature of their disease. Tuberculosis of the hand, the lesion small or large in area, often painless, and unrecognized as such for a long while, and perhaps untreated, is by no means an infrequent occurrence. Scabies, as we know, has a marked predilection for the hand. The germs of favus and ringworm find their nidus there. Need I mention others? Now, whether these conditions are the result of hand-to-hand contact or not does not matter. The conditions themselves are dangerous elements, and it is the consideration of such factors in the causation of disease that we are studying.

Most of us are familiar, either through reading or experience, with the classical finger chancre of midwives, dentists, physicians, surgeons, and nurses. We recognize that contact, and more likely in the presence of an abrasion, with the contaminated source has caused it there; we also recognize that laymen, in consequence of digital fondling of the female genital organs, are not exempt. Now as syphilis is most infectious during its primary and secondary stages, and as in the latter stage its diffusion may extend over the entire surface of the body—(and even in the former, though the lesion is hidden, the hand may still have its share of the virus through repeated fondling of the affected part)—are we not forced to recognize that surface contact, hand to hand, as well as by any other parts, is dangerous? Of course the mucous membrane serves as a better pabulum for the invasion and development of micro-organisms, but the skin is not absolutely negative in that respect, and, if it were, it would make little difference, as the two, skin and mucous membrane, are very often in close apposition with each other. We know that the hand has carried bacteria to the mouth, disseminating contagion in that way. Typhoid fever, Asiatic cholera, diphtheria, and other diseases are known to have been produced that way. Why search through medical libraries for similar and perhaps more conclusive evidence? The subject has passed the stage of novelty. So while we professional people are, by reason of our profession, forced to invite and then to battle (for we have antiseptics) with these enemies, there is no reason why we should unnecessarily and under the cloak of custom invite them and then leave them to do their harm. No antiseptics are ever thought of after the latter procedure, and it is this latter procedure which is practised by everybody throughout the civilized world.

Cleanliness is godliness. Filth is Satan's armor of defence. Medical cogitation and agitation have caused rapid strides in the advancement of the science of sanitation. We grope no more in the dark. The ideal, illuminated with the light of this century's inventions and discoveries, stands unveiled. Should we hesitate because there may be some obstacle in our path, or because the subject smacks more of the social than of the medical aspect, or should we systematically go to work and cause its extermination?

Treatment.—How shall we go about it and with what prospect of success? Customs and ceremonies of all denominations are prevalent among all nations both in civilized and savage life. The atrociousness of their character in the latter sphere passes the bound of human imagination in the former. Murder and rapine in its widest and most brutal sense have for their cloak and protection established customs; and an omission of such, where it is expected, is a sacrilege to established law and order. In their savage ignorance they are unconscious of the enormity of their crimes. But we of the civilized world, and with a nineteenth-century enlightenment, can understand and look upon them with horror. We have by far surpassed their developmental stage and look forward to a grander one than our own, where harmful relics, now extant, will be entirely relegated to the past. Now can we help the natural evolution of this phase of sociology along? History repeats itself. Let us look to history for information.

In the reign of Alexander the Great, when his Majesty was afflicted with wryneck, all his courtiers and generals considered it the correct thing to carry their heads on one side. Soon the public followed. This, of course, spread like wildfire. However, the king recovered from his malady; his courtiers and generals recovered; the public recovered. The people at that time wanted a guide whom they could ape or follow. Not more than twenty years ago the Princess of Wales sustained an injury to her knee which caused her to limp. "My ladies" at court limped; the public limped—all England limped. In the course of time the princess recovered. "My ladies" at court recovered; all England recovered. So we see that the people now also want a guide, some one to ape or to follow. The imitative faculty which is part of our mental makeup existed during the time of Alexander the Great; it exists to-day. Many customs and costumes are repeatedly introduced and as many repeatedly forgotten; none in itself essential to our well-being, or not to be replaced. Those of medical consequence were discussed by physicians, and the mere discussion of them by physicians either gave them the stamp of approval or modified them so as to minimize their danger, or caused their total abandonment. New customs, social or otherwise, are, as a rule, in conformity with the advancement of the age which gives them birth, and either meet with corresponding changes as time goes on, or, in the event of their quiescence and relative regression, assume anomalous or destructive phases which justify an interference. The first step in the progress of interference, when a medico-social question is at issue, is its discussion by physicians, and this unconfined to Æsculapian walls. The next step is its discussion by the public. Our object is to start the wheel a-turning—reason and mimicry will do the rest. A simplification of matters in a delicate and unalarming way before the public eye, through the medium of the daily newspapers, would be a de-

sideratum here. The intelligence of the present age would at once grasp at the judiciousness of the project, and if it did not the intellect of social leaders would—the public later; and very soon the custom would become extinct, and so much would have been done toward disarming society of a universal custom which to-day has no rational significance, and which can and necessarily must perpetuate among us and among future generations irremediable disease.

Some may look upon this subject with derision; nevertheless the truth is this—no matter how small the percentage of evil consequencees accruing from this universal hand-shaking, the total number, in view of its extensiveness, must necessarily be great. The subject is deserving of serious consideration. Conscientious physicians and surgeons will accord it.

172 East Seventy-Second Street.

Progress of Medical Science.

A Method of Producing Immunity to Infection with Tuberculosis.—Paterson (*Lancet*, October 30, 1897, p. 1,106) found that while rabbits and guinea-pigs inoculated with the bacillus of mammalian tuberculosis by way of the peritoneal cavity, the anterior chamber of the eye, the veins, and the subcutaneous tissues, died from tuberculosis after the lapse of varying periods, invariably negative results were obtained from injections of the same organism into birds. On the other hand, birds treated with virulent avian tubercle bacilli showed after the lapse of a given time numerous tubercles in the viscera. Although it would thus appear that birds are not susceptible to infection with the bacilli of mammalian tuberculosis, human beings have proved susceptible to infection with the bacilli of the tuberculosis of fowl, and individuals so infected are in turn capable of transmitting the infection to birds. It was further found that pus from an abscess in a man proved capable of inducing tubercles in rabbits. While tubercle bacilli could not be detected in the pus, cultures from the tubercles showed the characteristic appearances of avian tubercle bacilli. Rabbits first inoculated with sterilized watery suspensions of avian tubercle bacilli and subsequently treated with suspensions of virulent mammalian tubercle bacilli, remained well, only local lesions developing. Fowl treated with increasing doses of sterilized watery suspensions of avian tubercle bacilli withstood the larger doses without apparent detriment to health. The blood serum of such animals displayed a bactericidal effect on mammalian tubercle bacilli, but not upon avian tubercle bacilli. Injection of the serum into rabbits and guinea-pigs was followed by the development of local swelling and loss of weight. Rabbits inoculated with mammalian tubercle bacilli and treated with the serum displayed a marked local reaction and only local lesions. In animals first treated with the serum and afterward inoculated with virulent mammalian tubercle bacilli, only local lesions developed. Injection of the serum into a man gave rise to marked local and constitutional reaction. The opinion is expressed that if such susceptible animals as guinea-pigs can be rendered immune, as much may be expected of man also. It is uncertain how long the immunity thus conferred lasts, but under the least favorable conditions it can be renewed from time to time.

The Employment of Saccharomyces in the Treatment of Tuberculosis and Carcinoma.—Manders (*British Medical Journal*, No. 1,917, p. 802) details the method devised by Backer in the treatment of tuberculosis and carcinoma. It had been observed that the saccharomyces possess under certain conditions phagocytic powers similar to those of leucocytes. A pure culture of saccharomyces cerevisiæ was injected with aseptic precautions into a healthy guinea-pig, and produced little or no effect. Next, a healthy animal was injected with the pure culture mixed with a proportion of fermentable matter previously sterilized, and it was found that the yeast cells underwent multiplication and carried out the function of fermentation within the system of the animal. Then a guinea-pig was inoculated in the ear with diphtheria, and an injection of the mixture of pure culture with sterilized fermentable matter was administered subsequently, with recovery of the animal. Similar experiments were made with guinea-pigs rendered artificially tuberculous, and the results were so encouraging that observations upon human beings were next resorted to. It having been shown that the injections were not attended by harmful results, a number of cases of tuberculosis were subjected to the treatment, with most satisfactory results. Similarly good results are stated to have occurred in cases of carcinoma.

The Treatment of Diphtheria with Antitoxic Serum.—Clubbe (*British Medical Journal*, October 23, 1897, p. 1,177) has reported two parallel series of cases of diphtheria, each to the number of 300, one of which was treated with and the other without antitoxic serum, at the diphtheria branch of the Sydney Children's Hospital. In all the diagnosis was confirmed by the presence of Klebs-Loeffler bacilli. The report is especially interesting because the cases were all treated in the same hospital and by the same physician, and because the general management was in all essentially the same. Of the 300 cases treated without serum, 169 were in females and 131 in males. Of this number 142 recovered and 158 died—a mortality of 52.7 per cent.; 101 were cases of simple diphtheria, with recovery in 78 and death in 23—a mortality of 22.7 per cent.; 199 required tracheotomy, with recovery in 64 and death in 135—a mortality of 67.8 per cent. Of the cases treated with serum, 158 were in females and 142 in males. Of this number recovery ensued in 240 and death in 60—a mortality of 20 per cent.; 171 were cases of simple diphtheria, with recovery in 160 and death in 11—a mortality of 6.4 per cent. Tracheotomy was required in 129 cases, with recovery in 80 and death in 49—a mortality of 37.9 per cent. After the preceding report had been made, an additional 100 cases were treated with serum, with recovery in 81 and death in 19.

Pulmonary Tuberculosis and Childbearing.—In a paper read before the Obstetrical Society of Boston, Townsend (*Boston Medical and Surgical Journal*, October 14, 1897, p. 391) reaches the following conclusions: 1. Conception may take place even in advanced pulmonary tuberculosis. 2. The disease is generally held in abeyance during pregnancy, although it may advance or even originate at this time. 3. Labor is short and easy in proportion to the severity of the disease. 4. During the puerperium a rapid advance, leading in some cases to speedy death, occurs; or the disease may originate at this time. In either case the temperature chart suggests puerperal sepsis. 5. Premature labor is more common the more advanced the disease, although pregnancy often goes on to full term even in advanced cases. 6. The average weight of full-term children, as well as their general condition at birth, is not markedly below that of children of healthy mothers, except in the rare instances of congenital tuberculosis.

Hemorrhoids.—Tincture of horse chestnut in doses of from twenty to thirty drops, twice daily.—Artault.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, December 4, 1897.

THE PHYSICAL DEGENERACY OF THE NEGRO.

THE race problem in the South seems destined to be settled according to natural laws unless something is done, and done soon, to save the negro from the results of his own vices and neglect of elementary hygienic laws. The testimony of those who have studied this subject is all but unanimous, and it has received additional confirmation through the investigations of Dr. R. H. Johnson, of Brunswick, Ga., himself a colored physician. The figures which he has gathered from a study of the vital statistics of nearly three hundred towns in the Southern States show that the death rate of negroes is double that of whites in the same communities, and not only this, but the birth rate is also smaller among the colored than among the white population. Furthermore, the day of the stalwart negro is passing, if not already gone, and the members of the younger generation of the race make a poor showing, as regards their size and physical constitution, when compared with their grandfathers and grandmothers.

Dr. Johnson attributes this degeneracy of his race —rightly, we believe—to the carelessness, want of forethought, and dissipation so unfortunately characteristic of a large portion of the colored population in the South since the civil war. "In antebellum days," says Dr. Johnson, "the negro seemed to be an immune to consumption, and many great medical writers and teachers boast of never having seen such among the negroes. Enforced temperate living and sanitary precautions made the black man a physical giant, but the giants are disappearing, and in their places is coming on a race of smaller stature and decreased vitality."

In the days of slavery the colored man was property and was looked after with all the care which men are accustomed to give to the safe-keeping of their possessions. Their health was carefully attended to by the plantation physician, they were decently housed, well fed, forced to live temperately, and to go to bed in proper season. But the fortunes of war, while giving them liberty, gave them also license to indulge in all the enervating and physically degrading vices of the higher race at a time when they had not learned the necessity of self-restraint and of regard for the laws of health.

That this is the true reason of the colored man's physical deterioration is further shown by what Surgeon-General Sternberg has to say, in his recently issued annual report concerning the health of the colored soldiers. "Great improvement," he says, "has taken place in the past few years in the sanitary condition of the colored troops. The white troops have participated in the improvement, although their rates have not fallen so rapidly as those of the colored men. During the past year the total hospital admission rate for all causes among the colored troops was 868.88 per 1,000 of strength, as compared with 1,132.49 among the whites, and as compared with 915.88 among themselves in the previous year, and with 1,368.64, their own annual average for the previous decade, the annual average of the white troops having been 1,284.95. The non-efficiency from all causes among the colored troops during the year was 25.75 per 1,000 of strength, as compared with 34.72 among the white troops. The colored soldier lost 9.42 days from disability during the year; the white soldier, 12.71; and the average time of treatment of each case was, among the colored troops, 10.84 days; among the white, 11.22 days. The causes of disability from which the colored men suffered less than the white troops were malarial fevers, venereal diseases, alcoholism, diarrhœa, and injuries; those from which they suffered more were neuralgia, rheumatism and myalgia, tonsillitis, colic and constipation, conjunctivitis, and pneumonia."

These figures contain much to encourage those who have the future of our colored brothers at heart and who have looked with sorrow upon their downward progress since the day of their emancipation. The figures show, indeed, that the race is capable of regeneration, since even now its members living under the sanitary and moral restraint of army discipline are found to be superior to their white comrades living under the same conditions. The proof exists that the colored race may yet be brought back to its former high sanitary condition, but the problem remains how to lift it up from the abyss of misery and how to avert its threatened extinction. Here is a task for the colored members of our profession, which they can accomplish far better than their white confrères and which calls for their best thought and self-sacrificing devotion.

MALE NURSING IN ENGLAND.

THE Hamilton Association for providing trained male nurses was started twelve years ago, as some of our readers may recollect (see MEDICAL RECORD, June 6, 1885), and the twelfth annual report is now before us. From this we learn that even after so long a trial the association is not yet self-supporting, although many hundreds of pounds were given by the benevolent foundress—the late Miss Jane Hamilton, who at her decease left a further sum of money to continue the work. From the first the association secured the support of the leaders of the English profession, some of whom have served on the committee of management. Nevertheless, the large general hospitals of London have hitherto given only a very one-sided support to

the movement, although the association supplied them for years with men nurses for emergencies, and that at a rate which entailed a loss to the funds in every case. Miss Hamilton was desirous of establishing a training-school at one of these hospitals and would have endowed it, but none of them seems to have been willing to give up a men's ward to nursing by men. This seems a very strange circumstance to us in this city, where the training-schools for male nurses have from their inception been located in the large general hospitals, and we can only suggest as an explanation that the nursing of the English hospitals is in the hands of some narrow-minded women, who oppose any encroachment on what they consider their natural domain. If so, it seems a pity that some hospital committee has not the courage to override the foolish jealousy of its matron or nursing superintendent.

That there is a need for male nursing in London, and that some women recognize the need, were well shown early in the year by an article in the *Nineteenth Century*, from the pen of Lady Priestley, who emphasized the widespread feeling that women are not suitable for nursing all cases, and urged the more general employment of male nurses. Lady Priestley seems, however, to have been strangely oblivious to the fact that the Hamilton Association, established and endowed for this end by one of her own sex, had for years been carrying out her ideas at her very door. Perhaps her position as the wife of a distinguished obstetrician may be the reason why her attention had not been drawn to the existence of the Hamilton Association, which is, we believe, the pioneer of male-nursing associations.

TREATMENT OF OZÆNA.

In a paper lately read at the Congress of the French Society of Otology, Laryngology, and Rhinology, by Dr. E. I. Moure, of Bordeaux, the treatment of ozæna was very fully discussed and some new lights are thrown upon a subject concerning which there is much yet to be learned. The bacteriological aspect of the disease is touched upon, and the various forms of treatment in vogue are cited. The author strongly deprecates operation as a remedy, and after briefly referring to treatment of ozæna by the introduction of bougies, snuffing, inhaling hot vapor, the use of ointment, massage, cauterization, he dwells at some length on interstitial electrolysis. Monopolar electricity was introduced as a remedy by Dr. Garrigon-Desarenès in 1884, who used it superficially. In 1895 Dr. Cheval, of Brussels, tried bipolar interstitial electrolysis, and claims great success from this mode of treatment. Dr. Bayer, of Brussels, and M. Rethi, of Vienna, agree with these conclusions.

Dr. Moure, however, dissents from these views. He gave interstitial electrolysis a fair trial, and while allowing that the immediate effects appeared very satisfactory, he found that this amelioration was but temporary. The treatment recommended by Dr. Moure is as follows: He first inquires of the patient whether he wishes to undergo a partial or regular course of treatment. If partial, the nasal cavities are first cleared by means of cotton wool soaked in carbolic glycerin; after this the nasal and post-nasal cavities are irrigated with some antiseptic wash. If, on the contrary, the patient wishes to undergo a regular course of treatment, in the first instance the nasal cavities are douched with a solution of boric acid; when this has been continued for a few weeks, the nasal mucous membrane is massaged with antiseptic cotton wool; nitrate of silver is then made use of; and, finally, an alkaline injection clears away any excess of nitrate of silver that may be contained in the interior of the nose. By these means it is contended that a definite cure may be obtained.

There are, however, many medical men who will prefer to try a more heroic form of treatment for the cure of ozæna than the foregoing. Dr. Mackenzie, of Edinburgh, says that ozæna is a disease of the mucous membrane, and that the atrophy or shrinkage which is a characteristic of it is due to pressure of the hardened pus (crusts) upon that membrane—a condition which is somewhat analogous to that met with in the skin in certain forms of eczema. He has endeavored by curetting to supplant the diseased membrane by new tissue, and claims to have met with great success from this treatment. After curetting, he uses oily applications, such as a mixture of ichthyol and olive oil, which he finds soothing and beneficial.

THE SLAUGHTER HOUSE IN RELATION TO DISEASE.

The growing danger of slaughter houses as a factor in spreading disease is at last being appreciated in its true bearings, and steps are being everywhere taken thoroughly to investigate the matter and to correct as far as possible the evils of the present system. There is much to be done, but as soon as the general public understands the nature of the perils to which it is subjected, owing to the unsanitary conditions under which slaughter houses are generally maintained, just so soon will they insist that remedial measures be taken. The most effective way to impress people with a sense of their danger is by pointing out to them that these unsanitary conditions are one of its sources, and to prove to them that unless radical remedies be put into force infectious diseases may increase to an almost unlimited extent.

Ch. Wardell Stiles, Ph.D., in a paper published in 1896, presents in a clear manner the subject of country slaughter houses as a factor in spreading disease. In the course of his remarks he says: "The first matter to notice in connection with this subject is that every slaughter house is, from the very nature of things, a centre of disease, and naturally the poorer the condition of the premises the more dangerous they are. These facts will appear clear if one considers what takes place at one of these houses. Even if only a few animals are slaughtered each week, the total number may amount to several hundreds during the year. Some of the animals are surely diseased. At least one of the hogs has trichinosis, and when the

offal of this trichinous hog is fed to hogs which are raised upon the grounds the latter cannot escape infection with trichinæ. But that is not all. The slaughter houses are often overrun with rats; the rats feed on the offal, and when feeding on the offal of a trichinous hog they likewise cannot escape infection with trichinæ. Rats act as direct transmitters of trichinosis to hogs." Dr. Stiles gives many more instructive details, but which we have not the space to quote. He summarizes thus: "Every slaughter-house is a centre of disease for the surrounding country, spreading trichinosis, echinococcus disease, gid, wireworm, and other troubles caused by animal parasites, and tuberculosis, hog cholera, swine plague, and other bacterial diseases. The important factors concerned in spreading these diseases are offal feeding, drainage, rats, and dogs." Two of the remedies suggested are as follows: "First, by a reduction in the number of premises on which slaughtering is allowed, on which account it is urged as all-important that there be a segregation of the slaughter houses, so that all the butchers of any given town will be compelled to do all their killing in a common, inclosed, and restricted area. In abandoning slaughter houses care should be taken to destroy the rats, in order to prevent the spread of infection. Second, by regulating the factors concerned in spreading the diseases: (*a*) offal feeding should be abolished; (*b*) drainage should be improved; (*c*) rats should be destroyed; and (*a*) dogs should be excluded from the slaughter houses."

This question of slaughter houses is attracting much attention in Europe, though chiefly in connection with tuberculosis, and some of the countries there have adopted stringent regulations controlling their management. The system in vogue in Denmark is said to be the most perfect. In Copenhagen every animal is after slaughter branded upon various parts of the carcass, and the brand is exposed in the butchers' shops to the public, which in consequence recognizes that the meat has been passed by the official inspectors as fit for human food. In England the question has only lately been seriously taken up. A royal commission has been appointed, members of which are at the present time visiting some of the principal towns in the kingdom for the purpose of collecting evidence. In France carcasses are seized when there are any visible signs of tuberculosis.

From abattoir statistics it is shown that in Berlin 12 per cent. of the cattle slaughtered are tuberculous; in Dresden, 14.4 per cent.; in Upper Silesia, 9.5 per cent.; in Durham, 18.7 per cent.; and in Mid-Lothian (a district in Scotland in which Edinburgh is located), 20 per cent. Of those slaughtered in London, 25 per cent. are diseased; and in New York, about 20 per cent. There can be no room for doubt that the sooner the task of putting all slaughter houses into a proper sanitary state is effectively carried out, the better will it be for the public health.

The New Hospital for Scarlet Fever and Diphtheria is to be opened for patients toward the end of the month of December.

THE ACADEMY OF MEDICINE AND THE NEWSPAPERS.

THE time to arrest an evil is at its inception, and for that reason we take occasion just now to utter a word of reproof to the officers of the New York Academy of Medicine. Through the negligence or the connivance of certain persons connected with this society, reports of the meetings of the general body and of individual sections have appeared in the daily papers with startling frequency and regularity this autumn. Reporters are not detailed to report medical meetings unless word is sent to the editors that the proceedings are to be of interest to the general public. The report of the annual meeting of the academy, with a full abstract of the anniversary address, is proper enough, for the occasion is intentionally made one of interest to the laity; but for reports of section meetings there can be no excuse whatever, except that of a desire to advertise boldly and baldly. The latest offence has been committed by the section on neurology and psychiatry.

News of the Week.

Care of Consumptives by the Board of Health.—The board of estimate and apportionment of New York has been asked by the health board to appropriate $60,000 for the care of tuberculous patients in Seton Hospital at Kingsbridge. It is said that the board can make arrangements with the authorities of this hospital for the care of consumptives at a *per-capita* rate of $1 a day. The argument is made that most of the hospitals are forced by want of room to refuse many applicants suffering from tuberculosis, and those that do accept patients of this class discharge them as soon as they are sufficiently improved to be able to get about, in order to make room for more desperate cases. For this reason, it is alleged, few hospital patients are ever cured, as they might be if cared for a sufficiently long period. But why should the health board take this matter in hand? It was not created to treat disease, but to prevent it. Why not leave the management of such hospitals to the Department of Charities, where it rightly belongs?

Typhoid in Paterson.—Typhoid fever has again broken out in Paterson, N. J., twenty-seven cases having recently been reported to the board of health, and fears are entertained that there may be an epidemic. Eleven of the cases are among the inmates of the Paterson Orphan Asylum.

An Impetuous Student.—A student from New York in a Chicago medical college was recently arrested for resorting to western methods to enforce his ideas of the proper treatment of a young woman by a fellow-student. He was walking with the lady when he met one of his classmates who had spoken of her without proper respect, and whipping out a revolver made the offender drop in his tracks in the mud of Chicago and apologize then and there.

New York Skin and Cancer Hospital.—Dr. Paul F. Mundé has been elected consulting gynæcologist to the New York Skin and Cancer Hospital, to succeed the late Dr. William T. Lusk.

Police Surgeon Examination.—At the recent examination for the position of police surgeon somewhat over eighty applicants presented themselves. Only four succeeded in reaching a percentage of 70 or over on the answers to the questions in medicine, surgery, physiology, and materia medica. The first man on the eligible list reached 94 per cent.; the second, 90 per cent.; the third, 80 per cent.; and the fourth, 77.6 per cent. The examination for merit also included an exercise in spelling and one in letter writing. The award for fitness, which counts 50 per cent. of the grand total, is based upon the general experience and standing of the candidates. The medical questions were fair ones, and the whole examination was conducted in a thoroughly business-like and straightforward manner.

Reception to a Physician.—A reception and banquet were tendered on November 24th to Dr. A. H. Halberstadt, of Pottsville, Pa., the oldest practising physician of Schuylkill County, by some fifty of his professional friends from all parts of the surrounding country. On behalf of his friends, Dr. W. H. Robinson, of Pottsville, presented a gold-headed ebony cane. Dr. R. S. Christman, of Pottsville, delivered a welcoming address. Dr. F. W. Boyer, of Pottsville, spoke upon "The Social Side of the Doctor's Life." The additional toasts were: Dr. David Taggert, of Frackville, "The Ladies;" Dr. J. E. Merkle, of Hecksherville, "The Doctor in Politics;" Dr. C. B. Miller, of Pottsville, "Medical Treatment;" Dr. G. H. Halberstadt, "Surgery."

Philadelphia County Medical Society.—A stated meeting of the Philadelphia County Medical Society was held on November 24th, the president, Dr. James Tyson, in the chair. Dr. T. B. Schneideman reported a case of sympathetic ophthalmia following traumatism, in which recovery followed enucleation of the exciting eye. Dr. Orville Horwitz read a paper in which he pointed out that the administration of methylene blue might serve a useful diagnostic purpose in distinguishing between fistulæ as connected with the genito-urinary tract and especially with the kidney or with other viscera. He reported a case in which the dressings covering a fistulous opening were stained blue following the administration of methylene blue, and he exhibited the deeply stained urine. He suggested further the possibility of facilitating skiagraphy of the kidney by the use of the drug. Dr. Judson Daland presented a communication detailing observations tending to show the inutility of tincture of digitalis administered in the form of tablets.

The Pittsburg Academy of Medicine.—The tenth annual meeting of this society was held on Thursday evening, December 2d, at the Hotel Henry. The annual address was delivered by Dr. George M. Sternberg, Surgeon-General, U. S. A., the subject being "The Relations of Man and Microbe."

Philadelphia Neurological Society.—A stated meeting of the Philadelphia Neurological Society was held on November 22d, the president, Dr. C. W. Burr, in the chair. Dr. W. G. Spiller reported two cases of posterior spinal sclerosis, in which the other symptoms remained in abeyance on the development of blindness and atrophy of the optic nerve, and he exhibited one of the patients. Neither of the cases presented noteworthy derangement of motility or co-ordination, and for this reason Dr. Spiller objected to the use of the term locomotor ataxia. Dr. Spiller also exhibited a microscopic section showing a neuromuscular bundle containing nerve fibres from a case of muscular dystrophy; and one of the optic nerve showing hemiatrophy from a case of acromegaly. Dr. F. A. Packard exhibited two brothers presenting progressive muscular dystrophy, with mental deficiency and possible enlargement of the thyroid gland. Dr. William Osler read a paper on paralysis of the hypoglossal nerve, reporting a case presenting hemiatrophy of the tongue, with paralysis of one side of the larynx and pharynx in conjunction with a tumor in the parotid region of the same side. Dr. C. W. Burr exhibited a brain presenting a large excavation in the motor area of either hemisphere near the longitudinal fissure, from a case in which during life there had been profound mental impairment and frequent epileptic seizures. Dr. G. M. Purves exhibited, for Dr. C. K. Mills, brains from two cases of intraventricular hemorrhage, and Dr. Mills made some remarks on the methods of dividing the brain at post-mortem examinations. Dr. J. P. Arnold reported a case of brain tumor situated on the median aspect of the left hemisphere, presenting during life right hemiplegia of progressive type, with optic atrophy, but without convulsions.

The Late Dr. Charles A. Avery.—At a stated meeting of the Medical Society of the County of New York, held at the New York Academy of Medicine, 17 West Forty-third Street, on Monday, November 22, 1897, the following resolutions were adopted:

"*Whereas*, Dr. Charles H. Avery, our esteemed and honored secretary, has been removed by death, which occurred November 2, 1897;

"*Resolved*, That we hereby express our deep sense of the loss which our society has sustained in his decease;

"*Resolved*, That we desire to bear testimony to the sterling integrity of his character, to his genial social qualities, and to his devotion to the interests of this society which he has so long faithfully and efficiently served in the capacity of secretary;

"*Resolved*, That a copy of these resolutions be transmitted to the medical journals of this city, and that an engrossed copy be sent to the family of our deceased associate.

"JOHN S. WARREN, M.D.,
"WILLIAM E. BULLARD, M.D.,
"*Committee.*"

Obituary Notes.—DR. GEORGE H. HORN, for many years secretary of the American Philosophical Society, died on November 25th, at the age of fifty-eight years. He was one of the leading entomologists of the United

States and an active member of the Academy of Natural Sciences. He was graduated from the Central High School of Philadelphia and from the medical department of the University of Pennsylvania.—Dr. J. E. Whiteside, of Philadelphia, died at Atlantic City on November 25th, at the age of seventy-four years. He was graduated from the Pennsylvania College at Gettysburg in 1844, and was engaged in the practice of medicine for fifty-three years.

Western Surgical and Gynæcological Association.—The seventh annual convention of this association will be held at Denver, Col., December 28 and 29, 1897.

American Association for the Study and Cure of Inebriety.—The twenty-seventh annual meeting of this association will be held December 8, 1897, in the hall of the Washingtonian Home, 41 Waltham Street, Boston, Mass. Several interesting papers are announced. The annual address will be delivered by Dr. Ira Van Gieson, of New York, "On Some Recent Researches on the Action of Alcohol on Brain Cells." Dr. Mason is president of the association, and Dr. T. D. Crothers, of Hartford, secretary.

The New Jersey Sanitary Association.—The twenty-third annual meeting of this association will be held at Lakewood, N. J., on Friday and Saturday, December 10 and 11, 1897. The sanitary association is composed of professors and teachers in New Jersey colleges and schools, municipal officers, health officers, lawyers, physicians, clergymen, civil engineers, sanitary engineers, architects, plumbers, and other citizens of the State, interested in sanitation as related to homes, schools, and municipalities. The objects of the annual meeting are the presentation of facts, the comparison of views, and the discussion of the methods relating to the prevention of sickness and of untimely deaths.

Rounding up Connecticut Doctors.—The police court in New Britain, Conn., presented a brilliant appearance a week before Thanksgiving, the usual motley group of drunk and disorderlies being replaced by a batch of nine physicians, all charged with neglect in making proper returns of certificates of birth. The Hartford County health officer was the prosecutor, and he had resorted to this means of reminding the delinquents of their duty after his letters of remonstrance had failed to have the desired effect. Each of the accused acknowledged his fault and was promptly fined $10 and costs, the latter bringing the total up to $19.07.

Kipling's Compliments to the Doctors.—Rudyard Kipling was a guest at the annual dinner of the Harveian Society of London, at the Café Monico, on November 25th, and replied to the toast of "The Visitors." He said he had come so near being a doctor in his youth as to be allowed to play in the neighborhood of St. Mary's Hospital. But later he had been thrown much in the company of medical men in all parts of the world, and he admired them. He had seen them going to certain death with no hope of reward, because it was "business." He had also seen them handling cholera and small-pox, and when dying therefrom wiring for a substitute. He had seen them in Vermont manage a practice twenty miles in each direction, driving horses through eight feet of snow to attend an operation ten miles away, and digging their horses out of the snow and proceeding. It was one of the proudest things of his life, he said, to have been associated with "real fighting men of this class."

Dr. Alfredo A. Kathnack, recently lecturer on pathology at St. Bartholomew's Hospital, has been elected to the professorship in that subject at Cambridge University, in succession to the late Dr. C. S. Roy.

Intemperate Antiprohibitionists.—Dr. August Forel, professor of psychiatry in the University of Zurich and director of the State Asylum for the Insane, has resigned on account of the attacks made upon him by the press by reason of his strong opposition to the use of alcohol. The prohibitionists have for so long enjoyed almost a monopoly in illiberality that it must come somewhat as a shock to find such fanaticism exhibited on the other side.

A Difference of Opinion.—At an inquest held a short time ago in England on the body of a lad, sixteen years old, the jury found that the boy died from syncope, due to nicotine poisoning, caused by the excessive smoking of cigarettes. The coroner said there seemed to be quite an epidemic of such cases, and it was time the attention of parents was called to the danger of their children smoking at so early an age. In commenting upon this verdict, *The Lancet* agrees with the coroner and suggests an analysis of the tobacco which caused the boy's death. On the other hand, the editor of the *British Medical Journal*, while disclaiming any approval of indulgence in the cigarette habit by children, questions the accuracy of the verdict, and says that the coroner overstated the case when he asserted that there had been many deaths recently from this cause.

English-Speaking Practitioners in Italy.—At the last general medical congress held here it was unanimously voted that foreign medical practitioners professionally engaged in Italy should undergo a state examination or qualify at one or other of the Italian schools in order to legalize their practice. In consequence of this step a deputation of the English-speaking practitioners has just waited on Signor Serena, under secretary of state for the home department, to protest against such action. His excellency announced in reply that arrangements in the direction proposed by the Italian Medical Congress had not yet been taken, but that in any case the government before giving legal effect to the innovation contemplated by the congress would put itself in diplomatic communication with the governments of the other powers, with a view to obtaining for Italian practitioners in those countries the same privileges enjoyed in Italy by foreigners. The matter will probably rest there.—*The Lancet.*

Reviews and Notices.

CHIRURGIE DES VOIES URINAIRES: ÉTUDES CLINIQUES. Par le DR. E. LOUMEAU, Professeur Libre de Clinique des Maladies des Voies Urinaires. 2me Volume. Avec Planches hors Texte. Bordeaux: Feret et Fils, Libraires-Editeurs. 1897.

THIS is the second volume based upon the author's personal observation of cases, to which he has added such commentaries as have seemed necessary. Much of the matter has already been published in periodical literature or as communications to societies. A similar volume with the same title was published by the author some three years ago.

DIE HEFEN ALS KRANKHEITSERREGER. Von DR. OTTO BUSSE, Privatdocent für Pathologie und pathologische Anatomie in Greifswald. Berlin: August Hirschwald. 1897.

THIS short brochure, containing two colored plates and a number of other illustrations, represents the results of a careful experimental study of the yeast family of plants (blastomycetes, etc.) in the production of disease processes.

CYSTITIS UND URININFEKTION. Klinische, experimentelle und bakteriologische Studien, von DR. MED. MAX MELCHIOR, Privatdocent an der Universität in Kopenhagen, Fr. Chef des Laboratoriums und Secundarchirurg am Königlichen Friedrichs-Hospital. Berlin: Verlag von S. Karger. 1897.

THIS unbound volume of two hundred and thirty-eight pages without illustrations is a praiseworthy *résumé* of present knowledge concerning urinary infections and the results of bacteriological experimentation in cystitis, urethral fever, etc.

TECHNIK UND PRAKTISCHE BEDEUTUNG DER ASEPSIS BEI DER BEHANDLUNG DER HARNLEIDEN. Von DR. ROBERT KUTNER, Berlin. Berlin: August Hirschwald. 1897.

THE author has included in forty-two pamphlet pages many useful hints on the aseptic treatment of urinary derangements. There are eight illustrations.

FESTSCHRIFT EDUARD HAGENBACH-BURCKHARDT, Professor der Kinderheilkunde und Director des Kinderspitals in Basel, zu seinem 25jährigen Professoren-Jubiläum. Gewidmet von seinen Schülern. Basel und Leipzig: Carl Sallmann. 1897.

THIS jubilee production by the author's pupils contains a number of well-written and interesting theses; one on congenital malformations is well illustrated by two plates containing many interesting specimens.

SPECIELLE DIÄTETIK UND HYGIENE DES LUNGEN- UND KEHLKOPF-SCHWINDSÜCHTIGEN. Von DR. FELIX BLUMENFELD, Wiesbaden. Berlin: Verlag von August Hirschwald. 1897.

MANY useful hints in the management of consumptive patients will be found to repay the reader. There are about one hundred pages of text.

A PICTORIAL ATLAS OF SKIN DISEASES AND SYPHILITIC AFFECTIONS. In Photo-Lithochromes from Models in the Museum of the St. Louis Hospital, Paris. With Explanatory Woodcuts and Texts by ERNEST BESNIER, A. FOURNIER, TENNESON, HALLOPEAU, DU CASTEL, HENRI FEULARD, L. JACQUET. Part XI. Edited and annotated by J. J. PRINGLE, M.B., F.R.C.P. London: The Rebman Publishing Company, Ltd. Philadelphia: W. B. Saunders. 1897.

THE first plate presents the interesting conditions of hydroic erythema of the hands and lips, for which the text has been written by Du Castel. The next plate, representing the pigmented syphilide, has nothing special to commend it, and one is at a loss (unless thoroughly familiar with the subject) to guess from what portion of the anatomy the picture is taken. Whenever a question of anatomical location could arise it would be much better if the region from which the model was made were indicated on the plate. The other, representing molluscum contagiosum, the text of which is written by Baudouin, is of special value in differentiation of these lesions from a syphilide. Plate 44, showing nævi of the leg, described by Gaucher, is of interest more as a curiosity than because of its great practical importance. The pigmentation from pediculosis is strikingly portrayed in a typical picture of the back.

RHEUMATISM AND ITS TREATMENT BY THE USE OF THE PERCUSSO PUNCTATOR. By J. BRINDLEY JAMES, M.R.C.S. Eng., Licentiate of the Royal College of Physicians of Ireland; Associate of King's College, London; Author of "Replies to Questions in Therapeutics." Second edition. The Rebman Publishing Company, Ltd. London. 1897.

THIS is a second edition of a very brief account of the author's invention for making acupuncture over the seat of painful affections. The first appeared some ten years ago. He also employs injections of sulphuric ether, dry cupping, and internal medication.

INTERNATIONAL CLINICS: A Quarterly of Clinical Lectures on Medicine, Neurology, Surgery, Gynæcology, Obstetrics, Ophthalmology, Laryngology, Pharyngology, Rhinology, Otology, and Dermatology, and Specially Prepared Articles on Treatment. By Professors and Lecturers in the Leading Medical Colleges of the United States, Germany, Austria, France, Great Britain, and Canada. Edited by JUDSON DALAND, M.D. (University of Pennsylvania), Philadelphia, Instructor in Clinical Medicine, and Lecturer on Physical Diagnosis in the University of Pennsylvania, Assistant Physician to the Hospital of the University of Pennsylvania; J. MITCHELL BRUCE, M.D., F.R.C.P., London, England, Physician to and Lecturer on the Principles and Practice of Medicine in the Charing Cross Hospital; DAVID W. FINLAY, M.D., F.R.C.P., Aberdeen, Scotland, Professor of Practice of Medicine in the University of Aberdeen; Physician to and Lecturer on Clinical Medicine in the Aberdeen Royal Infirmary. Volume XI., Seventh Series. Philadelphia: J. B. Lippincott Company. 1897.

THE volume at hand is quite up to the average of this well-edited series of monographs and lectures.

The contributors are as usual chosen with deliberate care. The lectures are conveniently classified under therapeutics, medicine, neurology, surgery, etc. The first, by Edward Jackson, is a very short chapter on the treatment of presbyopia. Indeed most of the chapters are short and correspondingly attractive. This also makes it possible to include in the volume the writings of many more authors than is possible when long-drawn-out discourses are accepted. Not only is the quality of the writings being maintained, but the general make-up of the book is very satisfactory.

The illustrations are not so numerous nor are they so good as in many former volumes of the series.

JOURNAL OF THE MILITARY SERVICE INSTITUTIONS OF THE UNITED STATES. Vol. XX., No. LXXXVI. March, 1897.

THIS is a bimonthly publication edited by James C. Bush. The present number contains interesting articles on proper military institutions, by Wagner, Foote, and Steele. It offers besides much that is of interest to military men.

THE ORIGIN OF DISEASE, ESPECIALLY OF DISEASE RESULTING FROM INTRINSIC AS OPPOSED TO EXTRINSIC CAUSES. By ARTHUR V. MEIGS, M.D., Physician to the Pennsylvania Hospital. 8vo, pp. 229. Philadelphia: J. B. Lippincott Company. 1897.

THIS well-written and logically suggestive work is upon a topic of wide interest to every thoughtful reader, and gives much food for the earnest study and careful differentiation of long-accepted facts. The courage evinced by the author in combating many of the time-worn theories regarding the intrinsic and extrinsic origins of disease will be duly appreciated by all who may be interested in a very broad subject treated in a philosophical manner from a conscientiously comprehensive point of view. The writer follows a very consistent line of argument, which tends to prove that in all human beings there is a latent tendency to disease that resembles in a striking way the ordinary physical changes of progressive decay. The latter is made manifest more par-

ticularly in the study of the varied conditions associated with fibrosis in the different tissues of the vital organs. The facts bearing on this view are adduced from the study of a large number of microscopical lesions of the vessels and parenchymata of the organs in question. It is the careful consideration of these data that leads to the almost inevitable conclusion that no one organ is a leading factor, but rather that each is a part of a whole, in a general degenerative process. The views on the duality of phthisis, and the differences between inflammatory and strictly tuberculous degenerations, are particularly interesting in view of the generally accepted beliefs to the contrary. The same may be said from the standpoint of novelty regarding the multiple character of Bright's disease, and the ingenious disproof of the tenability of compensatory cardiac hypertrophy in valvular affections. Altogether the volume deals very exhaustively with the subject in hand, and is an efficient aid to every one who may wish to reconcile the facts of clinical experience with the actual demonstration of associated pathological lesions.

THE SURGICAL PECULIARITIES OF THE AMERICAN NEGRO. A Statistical Inquiry Based upon the Records of the Charity Hospital of New Orleans, La., Decennium 1884–94. By RUDOLPH MATAS, M.D., Professor of Surgery, Medical Department, Tulane University of Louisiana; Visiting Surgeon to the Charity Hospital of New Orleans.

THIS brochure of one hundred and thirty pages, reprinted from the transactions of the American Surgical Association for 1896, deals with a great variety of interesting conditions, which the author has carefully worked up from several different standpoints. The diseases of the skin have been made the subject of a special study by Dr. Dyer, also of New Orleans Charity Hospital, which is added as an appendix. Data from various sources have been incorporated, and quite a lengthy bibliography closes the volume.

REPORT OF THE PASSAIC VALLEY SEWERAGE COMMISSION UPON THE GENERAL SYSTEM OF SEWAGE DISPOSAL FOR THE VALLEY OF THE PASSAIC RIVER, AND PREVENTION OF THE POLLUTION THEREOF. Newark, N. J., February, 1897.

THIS report contains valuable data and a large map of the district in question. In a brochure of one hundred and thirty pages, the author has collected much interesting data bearing upon the question in hand.

PRACTICAL NOTES ON URINARY ANALYSIS. By WILLIAM B. CANFIELD, A.M., M.D., Lecturer on Clinical Medicine, University of Maryland; Visiting Physician to the Union Protestant Infirmary, Bay View Hospital. Second Revised Edition. Detroit: George S. Davis.

THE present edition of Dr. Canfield's hundred-page brochure has been revised so as to cover the ground and include the more recent methods of urinary analysis.

LECTURES ON APPENDICITIS AND NOTES ON OTHER SUBJECTS. By ROBERT T. MORRIS, A.M., M.D., Fellow of the New York Academy of Medicine; American Association of Obstetricans and Gynæcologists; American Medical Association. Second Edition, Revised and Enlarged. With Illustrations by HENRY MACDONALD, M.D. New York and London: G. P. Putnam's Sons.

THE present volume has been somewhat increased in size and modified in text. The work is practically a collection of lectures embracing the author's views upon the very important and interesting subject.

There are added (under the heading of "Notes") a series of short articles upon important surgical topics, which equal in space covered, illustrations, and general interest the lectures proper.

HAND-BOOK FOR HOSPITALS. By ABBY HOWLAND WOOLSEY, Member of Committee on Hospitals of the State Charities Aid Association. Third Edition. New York and London: G. P. Putnam's Sons.

THIS is No. 32 of the New York State Charities Aid Association Series. A special committee on revision of this handbook, consisting of Drs. Hitchcock, Wheelock, and Gill Wylie, has collected a mass of special information here embodied, which will be found of great use to charity commissioners, superintendents of poor, and those engaged in the management of hospitals, asylums, and institutions in general. It embraces information on water supply, drainage, housekeeping, nursing-services, disinfection, etc.

ADDRESS ON IMMUNITY TO DISEASE. By W. B. RANSOM, M.D., M.A., M.R.C.P., Physician to the General Hospital, Nottingham. London: John Bale & Sons.

THIS is the presidential address delivered before the Nottingham Medico-Chirurgical Society. It deals in an exceptional manner with a very interesting question.

A CLINICAL, PATHOLOGICAL, AND EXPERIMENTAL STUDY OF FRACTURE OF THE LOWER END OF THE RADIUS, WITH DISPLACEMENT OF THE CARPAL FRAGMENT TOWARD THE FLEXOR OR ANTERIOR SURFACE OF THE WRIST. By JOHN B. ROBERTS, A.M., M.D., Professor of Anatomy and Surgery in Philadelphia Polyclinic; Professor of Surgery in the Woman's Medical College of Pennsylvania. With 33 illustrations. Philadelphia: P. Blakiston, Son & Co. 1897.

THIS little work of seventy-six pages deals with specimen cases, experimental observations, causes and mechanism, symptoms, diagnosis, and treatment of the injury described.

PROCEEDINGS OF THE NEBRASKA STATE MEDICAL SOCIETY. Twenty-ninth Annual Session, 1897. Published by the Society.

THREE hundred and seventy three pages of well-prepared, well-printed, and well-bound papers, with frontispiece picture of President Haldeman.

ANNUAL REPORT OF THE STATE BOARD OF CHARITIES FOR THE YEAR 1896. Transmitted to the Legislature February 25, 1897. Albany and New York: Wynkoop-Hallenbeck-Crawford Company. 1896.

THIS is the usual senate report, and it contains much of statistical interest.

THE AMERICAN ACADEMY OF RAILROAD SURGEONS. Report of the Third Annual Meeting held at Chicago, Ill., September 23, 24, and 25, 1896. Edited by R. HARVEY REED, M.D., Columbus, Ohio. Chicago: American Medical Association Press. 1897.

BESIDES the usual number of surgical papers, this volume contains good pictures of Dr. J. E. Owens, of Chicago, as a frontispiece, and of Drs. Harnden, of Waverly; Dooley, of Buffalo; and Peck, of Utica, New York, which make the volume the more worth keeping.

A MANUAL OF LEGAL MEDICINE FOR THE USE OF PRACTITIONERS AND STUDENTS OF MEDICINE AND LAW. By JUSTIN HEROLD, A.M., M.D., formerly coroner's physician of New York City and County, etc. 8vo, pp. 678. Philadelphia: J. B. Lippincott Company. 1898.

THE wide and varied practical experience of the author as coroner has well qualified him for the task of presenting, in a condensed form, the fundamental principles of medical jurisprudence, and an abundant evidence of the fact is the general character of the work itself. No attempt has been made to write an exhaustive treatise, but the skill shown in the selection of essential salient points of the varied topics considered amply compensates for that illustrative detail expected in more elaborate works. The general field is well covered and the arrangement is consistently systematic. The work is divided in two parts, the first treating of toxicology, and the second of forensic medicine proper. The classification of drug poisons is complete enough for practical purposes and the chemical tests for their detection are clearly presented. The toxic phenomena are well described and the points of diagnosis are well considered. In part second, the more important portion of the volume for practitioners, there is a full exposition of the facts connected with wounds as various causes of death in murder and suicide cases, and of the legal relations of supposed accidents with suspected murder. In this connection the pathological conditions of drowning are very lucidly described, and the differences between antemortem and post-mortem immersion are properly explained.

Due attention is also given to malpractice cases, to matters of contributory negligence connected therewith, and to the relations of death in criminal cases with negligence or want of skill in the practitioner. Deaths by electricity also form a very interesting portion of the book. The appendix contains a medico-legal description of several recent leading criminal cases, notably those of Carlisle Harris, Meyer, Holmes, and Robert W. Buchanan.

Appendicitis and its Surgical Treatment, with a Report of Seventy-Five Operated Cases. By Herman Mynter, M.D., Professor of Operative and Clinical Surgery in Niagara University, Buffalo, N. Y. 8vo, pp. 302. Philadelphia: J. B. Lippincott Company. 1897.

This volume on the absorbing topic of appendicitis is a very careful and quite exhaustive study of the subject, ostensibly from the surgeon's point of view. One of the chief characteristics of the volume is its carefully prepared bibliography, showing painstaking accuracy in the numerous quotations from authorities. The author accepts the view of the bacterial origin of the disease and the marked predisposing influences of malpositions as the direct results of initiatory inflammatory attacks. The medical treatment is viewed quite impartially and gives greater strength to the arguments in favor of radical surgical measures. The well-written reports of seventy-five operative cases fully attest the soundness of the author's views as to early interference.

A System of Practical Medicine by American Authors. Edited by Alfred Lee Loomis, M.D., LL.D., Late Professor of Medicine in the New York University, and William Gilman Thompson, M.D., Professor of Materia Medica, Therapeutics, and Clinical Medicine in the New York University, Physician to the Presbyterian and Bellevue Hospitals, New York. Volume II. Diseases of the Respiratory System and the Mediastinum, Diseases of the Blood, Diseases of the Kidneys, Diseases of the Bladder and Prostate Gland. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1897.

The contributors to this second volume include besides the late Dr. Alfred Loomis and Dr. Henry P. Loomis, such names as Solly, Tyson, Whittaker, Fitz, Coleman, Mason, and a number of others. The general scope and make-up of the work quite come up to the standard promised in Volume I. The pulmonary diseases have come in for a large share of careful consideration, and are treated of, in part at least, in a masterly way. The contribution from Loomis himself upon endocarditis, though not especially long, elucidates the subject in a very complete and satisfactory manner. Next to the diseases of the lungs come those of the kidneys, so far as space occupied and careful preparation are concerned. The blood, in its various pathological changes, has received a large amount of attention at the hands of Shattuck and Cabot, making a very interesting and instructive chapter illustrated with no less than three colored plates besides the woodcuts. The illustrations throughout the work are numerous and excellent. No chapters can be picked out as presenting evidences of greater care and preparation than others; still upon a cursory review those upon the physical signs of pulmonary diseases, hay fever, asthma, heart disease, endocarditis, and the non-tuberculous diseases of the pleura appear to have been prepared for the reader with conscientious consideration.

A System of Practical Therapeutics. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, Physician to the Jefferson Medical College Hospital. Volume IV. With Illustrations. Philadelphia and New York: Lea Brothers & Co. 1897.

This fourth volume covers the field of hydrotherapy, climate, infections, diseases of the respiratory, digestive, genito-urinary, cutaneous, and nervous systems, and diseases of the eye and ear.

We believe that the editor of this system has been governed by wisdom in urging his authors to include in their special departments illustrative prescriptions with dosage and directions for the requirements of given conditions. He very justly says: "The practising physician wishes to know how the author himself would use the remedies he commends, if he were at the bedside." In spite of this policy the prescriptions are not profuse, even in the editor's own chapters, one of which, dealing with scarlet fever and measles, is strikingly brief. Diseases of the blood are more briefly considered than is customary to-day in the larger works on medicine.

We must not forget, however, that we have before us a system of therapeutics, and not a treatise upon general medicine. Taken altogether, this volume is of equal excellence with those already published, and, although the illustrations are few, the text is for the most part presented in a very readable manner. The list of contributors contains many of the best-known American names.

Anomalies and Curiosities of Medicine. An Encyclopædic Collection of Rare and Extraordinary Cases, and of the Most Striking Instances of Abnormality in All Branches of Medicine and Surgery, Derived from an Exhaustive Research of Medical Literature from its Origin to the Present Day, Abstracted, Classified, Annotated, and Indexed. By George M. Gould, A.M., M.D., and Walter L. Pyle, A.M., M.D. Philadelphia: W. B. Saunders. 1897.

It is with somewhat of a "dime-museum" feeling that one opens this volume of human freaks, and one is likely to ask himself at the threshold whether or not he is "glad he came." A fascination, however, leads him from one anomaly to another, until he finds himself studying monstrosities, deformities, congenital and acquired, of every variety of which mortal has ever dreamed, and many which could scarcely enter the imagination in the wildest delirium. It is a large volume, and, while by no means exhausting the extensive subject, it contains a classified collection of a large number of rare and remarkable specimens illustrating what deviations from the normal human nature is capable of. As an epitome of the literature of medical freakdom the work will fill a place as a book of reference, especially if in future editions certain chapters are supplemented so as more perfectly to cover the field. Sexual peculiarities take up a large space, while pathological growths attaining unusual proportions are included among the curiosities, along with joined twins, triple monsters, horned men, and bearded ladies. The index is quite long but lacking in many particulars, and should be supplied with cross-references. A partial bibliography, ranging from Nos. 100 to 847, is arranged so as to save footnote space. Too many of the interesting conditions depicted and described are not entered in this list. The illustrations are numerous and naturally supply the chief charm of the work, which will interest natures of a morbidly curious trend no less than those scientifically inclined.

Painful Cystitis in Women Treated by Vesical Curetting.—Camero claims that the lesions of cystitis are more frequently localized about the neck of the bladder and of the trigonum. In extreme cases we have an interstitial cystitis which seems to be beyond therapeutic measures. It has been observed that even when the pain was intense the mucous membrane was not deeply involved. In such cases vesical curetting is productive of good. The operation should be preceded by thorough lavage of the bladder, with a solution of boric acid to which is added one per cent. of a solution of bichloride of mercury of the strength of 1 to 1,000. The doctor concludes his article as follows: "1. Painful cystitis is particularly frequent in women. 2. The measures to be resorted to should consist of the treatment of the uterus and its adnexa and general treatment. 3. The local treatment of cystitis, although easy in light cases, becomes insufficient in pronounced cases. 4. Surgical treatment becomes necessary in cases in which the pain is intense. 5. Cystotomy, particularly colpo-cystotomy, should be reserved for very serious cases. 6. Very often recovery or a step toward recovery by means of local topical treatment may be obtained by curetting the bladder through the urethra. 7. This operation is simple and easy; it does not require any complemental operation, and it gives excellent results."—*Gazette hebdomadaire de Médecine et de Chirurgie.*

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Regular Meeting, Held in Jersey City, October 15, 1897.

W. GILMAN THOMPSON, M.D., PRESIDENT, IN THE CHAIR.

A Case of Pulmonary Tuberculosis Complicated by Pneumo-Hydrothorax, with Some Unusual Features.—The patient, presented by DR. A. A. SMITH, was a man thirty-five years old, a gripman by occupation, who first came to Bellevue Hospital in January, 1897. During the previous summer he had been ill enough for the railway company to grant him a vacation, and when he returned to his work his condition was unimproved; he suffered from cough, shortness of breath, a certain amount of fever, and on one occasion he expectorated a small quantity of blood. About two weeks before he entered the hospital he had had a violent attack of coughing, with moderately severe pains which he referred to the lower axillary region. At no time had he had any severe pain higher up in the thorax.

Upon his admission to the hospital the physical examination revealed a rather curious condition. There were evidences of consolidation of the right lung with marked thickening of the pleura over the upper thoracic region, extending down to the inferior angle of the scapula; below that there was a very marked tympanitic percussion sound, and over that area there was an entire absence of vocal fremitus with distinct amphoric breathing. The diagnosis of pulmonary tuberculosis complicated by pneumothorax was made. Within forty-eight hours succussion sounds were heard, with distinct evidence of a pneumo-hydrothorax. There was marked dyspnœa, which was relieved by the withdrawal of a portion of the fluid by aspiration. In the course of a few days the cavity refilled and was again aspirated. Subsequent to this the symptoms of pneumo-hydrothorax entirely disappeared and he improved rapidly during the past summer, gaining nine pounds in weight. In September, however, his pulmonary symptoms became more acute, and he developed a laryngitis which was tuberculous in character; another serous effusion also took place, and a large quantity of fluid was withdrawn.

Dr. Smith said the point of special interest in connection with the case was the improvement that occurred subsequent to the attack of pneumo-hydrothorax. At the present time the physical signs were those of consolidation at the apex of the right lung, with marked thickening of the pleura, extending from about the middle of the scapula to the base of the lung. No tubercle bacilli had been found in the fluid withdrawn from the chest, although they were found in the sputa.

Acute Serous Meningitis.—DR. C. L. DANA read a paper on this subject (see page 801).

DR. G. L. PEABODY said this condition of "wet-brain," so called, was one with which all who had had much pathological experience in hospital practice were thoroughly familiar. The speaker confessed that he had never ascribed to it the importance attached to it by Dr. Dana, nor had he ever regarded it, strictly speaking, as an inflammatory process—of which, in fact, Dr. Dana had found no evidence. Dr. Peabody said he had always looked upon this condition as a part of the general atrophic changes which occurred in the organs of alcoholic patients. We knew that in this class of cases atrophic changes took place in the more important glandular structures, particularly in the stomach, liver, and kidneys, and even the obesity produced by alcohol was now regarded as an evidence of malnutrition—it was really an atrophic condition. It would be fairer, the speaker thought, to infer that the serous exudates described by Dr. Dana were the result of an antecedent atrophy of the brain tissues. There was an exudation of serum to take the place of the brain tissue which had been lost by the atrophic process. In conclusion, Dr. Peabody said that he did not wish to be understood as denying the conclusions set forth by Dr. Dana. Because of the absence of so many of the usual typical symptoms of meningitis, however, and, further, because of the fact that many alcoholic patients who died had an abnormally dry brain rather than a wet one, he had been led to the belief that the condition referred to was the result of atrophic changes rather than an inflammation.

DR. DANA, in reply to a question as to how he tapped the spinal cord, said he had followed the method described by Quincke. The patient was placed on his side, with the head elevated and the trunk well flexed, and then a needle, about five inches long, was passed in between the second and third lumbar vertebræ directly between the spines in children, and about one-fourth of an inch to one side in adults. Dr. Dana said that the operation, while it required a little skill, was comparatively simple, and the needle usually at the first attempt slipped right in, and its insertion was generally followed by a spurt of fluid, which was permitted to run until three or four drachms, sometimes only one drachm, and sometimes even one ounce or more had escaped.

DR. BEVERLEY ROBINSON spoke of two cases at St. Luke's Hospital, in which tapping the spinal cord had been resorted to. The first case was one of obscure spinal trouble. The patient was going from bad to worse, and it was finally decided to tap the cord. This was done, but no fluid followed the insertion of the needle. The case went on to a fatal termination, the patient apparently not having received any benefit from the operation. The second case was one of cerebro-spinal meningitis. The lower portion of the cord was tapped, and about four ounces of purulent fluid was withdrawn. No bacteriological examination was made. In that case the patient died during the tapping. Dr. Robinson said that in view of his experience with this operation, he should not care to resort to it again unless the conditions demanding it were very urgent.

DR. V. P. GIBNEY said he had performed tapping of the cord in cases of tuberculous meningitis with negative results. While he had never seen death occur during the operation, as in Dr. Robinson's case, or any harmful effects follow its performance, he had been rather impressed with the inutility of the measure in tuberculous meningitis. In cases like those described by Dr. Dana, he could understand the need of such a procedure, especially as he saw no particular objection to the operation. It was well known that a spina bifida could be tapped, and unless too much of the fluid was removed no ill effects would follow.

DR. ADAMI, of Montreal, was inclined to agree with Dr. Peabody that the condition described so fully by Dr. Dana might in the main be of the nature of a *hydrops ex vacuo*, secondary to atrophic changes in the cortex. The alterations in the cells described and illustrated might well be atrophic in character, and had there been an active pouring out of fluid, such as occurred in meningitis, he would not have anticipated such great variations in the amount of fluid secured by lumbar tapping. Judging from these great variations, it would appear rather that in this condition of the "wet-brain" of alcoholism there might be two factors in action to different extents at different stages or in different individuals—a passive pouring out of fluid to compensate for toxic atrophy of the brain substance,

and an active pouring out, obscurely inflammatory in character, as suggested by Dr. Dana.

Dr. H. M. Biggs said that while in Berlin, in the summer of 1896, he was informed by Professor Koch that at the Hospital for Infectious Diseases lumbar tapping was resorted to almost as a routine measure in differentiating between cerebro-spinal and other types of meningitis. In regard to the pathology of the condition described by Dr. Dana, the speaker said that while in the main he agreed with Dr. Peabody, that the process was secondary to an atrophy, still he thought the atrophy was not the only factor in its production. In addition to the increase of cerebro-spinal fluid secondary to the atrophy in the brain tissue, there was probably a further increase in the quantity of the fluid, due to the direct influence of the acute alcoholism. This seemed to the speaker probable, as it was not usual to see in autopsies on alcoholic subjects who had died suddenly or from the direct result of some other condition than acute alcoholism such a very great increase in cerebro-spinal fluid as was commonly found in chronic alcoholism with an acute alcoholism supervening and causing death.

Dr. A. A. Smith inquired whether Dr. Dana had found any connection between the condition described and changes in the kidneys.

Dr. Dana replied that he had found no such connection. In a number of the cases no evidences of nephritis had been found post mortem, and in those cases the condition of the brain was essentially the same as in those in which kidney lesions did exist. He was inclined to believe, however, that general arterial sclerosis accompanying chronic nephritis would be apt to accelerate this condition of "wet-brain" and render it more serious.

Dr. Thompson said that Dr. Dana had certainly given a very graphic clinical picture of this condition. He fully indorsed the view expressed by the writer that in the treatment of these patients food was of more importance than were stimulants. After lavage of the stomach the food could be introduced through the tube, with rectal alimentation in addition.

Dr. Dana, in closing the discussion, said he did not regard this condition as an inflammation, in the ordinary sense of the word, yet he thought it might be looked upon as an inflammation in the broadest definition of that word. The serous effusion was the result of a reaction of the cells to an irritant, and it was poured out in order to wash away the poisons resulting from cell degeneration. The speaker said he used the term meningitis because the clinical picture was very similar to one of meningitis. Often, at the post-mortem in these cases, a purulent meningitis was found which had not been recognized during life, because the symptoms corresponded simply to "wet-brain." In regard to the view expressed that the process was an œdema and the result of atrophy, he thought there was considerable truth in it, especially in the older cases; but this view could not hold good in the majority of cases, because the majority of these patients got well. They went through this process, showed all these symptoms, and then recovered entirely, with no evidences of brain atrophy afterward. Taking a general view of these cases, Dr. Dana said he was inclined to believe that the process was one which was more perhaps in the nature of a toxæmia than of an inflammation, and that there was some active change in the brain cells due to this toxic agent. In the fatal case narrated by Dr. Robinson the quantity of fluid removed—namely, four ounces—appeared to him to be rather large.

The Clinical Value of the Widal Test.—The author, Dr. W. Gilman Thompson, stated that at the meeting of the British Medical Association he had reported five hundred and three cases in which the Widal test had been employed, and from that series he had drawn some conclusions as to its value. Since then he had added to the above list fifty-one cases he had had in his own service at the Bellevue and Presbyterian Hospitals. The total number of cases, therefore, on which he was now prepared to report was five hundred and fifty-four; this did not include repeated tests made on the same patient. The tests were made by experienced bacteriologists connected with the board of health and with five different hospitals. In the majority of the cases those who made the tests had not seen the patients and knew nothing whatever about them. In one hundred and eighty-two of the cases there were undoubted clinical evidences of typhoid fever; in the remainder the test was made as a matter of routine. The test gave rise to very curious results in certain cases. In one instance, for example, four tests were made during the course of the fever without getting any result, but a distinct reaction was obtained during convalescence. In two other cases the reaction occurred only during the relapses. In the one hundred and eighty-two cases which were diagnosed clinically as typhoid fever the test gave a positive reaction. In six cases of undoubted typhoid the test failed absolutely. In a number of cases of malaria, pneumonia, and other diseases, positive reactions were also obtained, rendering the test somewhat unreliable from the clinical standpoint.

Dr. H. M. Biggs showed some cultures of the bacillus typhosus which had been prepared by a new method devised by Dr. Philip H. Hiss, assistant bacteriologist in the health department. As was well known, Dr. Biggs said, there had always been great difficulty in the isolation and identification of the typhoid bacilli in the fæces, and their differentiation from other bacilli of the "colon group"—at least, in their rapid and certain identification. Various methods had been devised to obviate this, none of which had been accurate or satisfactory in all respects; they involved either too much uncertainty or too much time and labor to be of practical value in a diagnostic sense. Dr. Hiss, he said, after a long series of experiments, had succeeded in finding two media which seemed to overcome the obstacles heretofore met with. He then gave the following abstract from a paper "On a Method of Isolating and Identifying the Bacillus Typhosus," which will shortly appear in the *Journal of Experimental Medicine*:

"Two media have been devised. One for the differentiation of the bacillus typhosus from the various members of the 'colon group' by tube culture, and one for the differentiation of the colonies of the bacillus typhosus from those of the 'colon group' by plate culture.

"The tube medium contains agar, 5 gm.; gelatin, 80 gm.; NaCl, 5 gm.; extract of beef (Liebig's), 5 gm.; and glucose, 10 gm. to the litre; and has a reaction indicating 1.5 per cent. of normal acid, phenolphthalein being the indicator.

"In this medium the growth of the typhoid bacillus produces a uniform clouding, at 37° C., within eighteen hours. The colon cultures do not give the uniform clouding, and present several appearances, dependent upon differences in their motility. [Tubes were shown.]

"The plating medium contains agar, 10 gm.; gelatin, 25 gm.; NaCl, 5 gm.; beef extract, 5 gm.; glucose, 10 gm. to the litre; and reacts two per cent. acid to phenolphthalein.

"The colonies of the bacillus typhosus in plate cultures made with this medium give rise to fringing threads and outgrowths, and are small. The colon colonies are larger and do not form threads.

"These colonies develop within eighteen hours, and the tube medium may then be inoculated from them. This in its turn gives its characteristic appearance in

eighteen hours, the whole process taking about thirty-six hours, at 37° C.

"The bacillus typhosus, alone of all the organisms investigated during these experiments, has displayed the power of giving rise both to the thread-forming colonies in the plating medium, and to the uniform clouding of the tube medium when exposed to a temperature of 37° C.; hence these two characters in combination have proved of great value in the isolation and identification of the bacillus typhosus, and will apparently prove diagnostic.

"The practical application of these media has led to the ready detection and isolation of the bacillus typhosus from the stools and urine of patients suffering from typhoid fever."

The value of this method was carefully tested on the fæces from a series of cases in the New York Hospital. There were twenty-six cases, of which nine were proven, both clinically and bacteriologically, to be not typhoid. Of the remaining seventeen, fourteen were in the febrile stage and three convalescent. The three convalescent cases were all negative. In thirteen of the fourteen cases in the febrile stage, typhoid bacilli were isolated from the stools.

The speaker said, in regard to the results in cases from other hospitals, that they were not so good as the investigators hoped to obtain in the future, because in many instances the stools were not received in a proper condition. In one instance the stool had been sterilizd with bichloride of mercury, and many of them had stood for from forty-eight to seventy-two hours. Of course the results in such cases could not be satisfactory. He had been informed by Dr. Hiss that it required on the average about one hour per case to make such an examination of the fæces, which, as compared with any other method for the separation of the typhoid bacillus, was an immense saving of time.

The health department, he said, had decided to add this method to the Widal test for the diagnosis of typhoid fever, and circulars of information had been issued. [A copy of the circular is printed in connection with this report.] In any case of suspected typhoid the health board would examine the stools or urine if the attending physician desired it. In a considerable number of cases of typhoid fever the bacilli were found in the urine, in how large a number was not known, but they were certainly present in a considerable proportion of cases. It was not known how early the bacilli appeared in the stools or how long they remained. In most of the cases which had been examined the disease was fairly well advanced. The sixth day was the earliest period at which the bacilli were found in the fæces, and it was the only case which was examined so early. In other cases the bacilli were found on the eleventh, twelfth, and thirteenth days, respectively, while in others they were found still later. In none of the cases did the bacilli persist during convalescence. In most of the cases when the temperature was normal the results were negative.

Dr. Biggs said that the conception of what typhoid fever is must be somewhat revised, or at least that term must be confined to that form of typhoid infection in which abdominal symptoms and lesions were present in the small intestines. Unquestionably cases of typhoid infection occurred in which there were no such lesions in the small intestines, and in which the usual manifestations of typhoid fever were absent.

Dr. Biggs took strong exceptions to the conclusions of Dr. Thompson. He thought that Dr. Thompson's description of the test was not sharply enough defined. The Widal test, when it was first described, was thought to be specific and qualitative. Soon afterward it was found to be simply quantitative. Merely to say that the reaction was obtained had little or no force, unless we could also say under what conditions it was obtained. At the laboratory of the health department the experience now probably covered between four hundred and five hundred cases of typhoid fever, and in no instance when the reaction was produced in the dilution of 1 to 20 had the final results shown that a typhoid infection did not exist. When a definite reaction was produced in a dilution of 1 to 20, the reaction taking place within a time limit of ten minutes, it seemed perfectly safe to assume that we had to deal with a typhoid infection. On the other hand, there was a considerable number of cases of undoubted typhoid infection in which the reaction was absent. Negative results therefore did not exclude a typhoid infection. The reaction might be absent throughout the entire course of the disease, or it might appear very late or even during a relapse, so that the absence of such reaction did not exclude the existence of typhoid, but the presence of the reaction under definite conditions entirely justified the assumption that the case was one of typhoid infection.

"Circular of Information Regarding the Separation for Diagnostic Purposes by a New Method of the Typhoid Bacilli from the Stools and Urine in Cases of Typhoid Fever.—The examination of specimens of blood from cases of suspected typhoid fever for the Widal reaction has been of great assistance in diagnosis. Occasionally, however, the agglutinating substances do not develop in the blood at any time, or only very late in the course of the disease, or an earlier infection cannot be excluded, owing to the lack of a reliable previous history. In these instances the Widal test fails to give the information desired.

"Bacteriologists have long sought for a rapid and certain method of obtaining and identifying in pure culture the typhoid bacillus from the stools and urine in cases of typhoid fever; but hitherto without satisfactory results. Dr. Hiss, assistant bacteriologist to the health department, has devised a method by which it is believed it will now be possible to recover and identify the typhoid bacilli within less than forty-eight hours, from specimens of fæces and urine containing them. The health department desires thoroughly to test this method, and is prepared to undertake these examinations if proper specimens are furnished.

"While definite knowledge is lacking as to the number of typhoid bacilli usually present in the stools of typhoid patients, and as to the time of their appearance and disappearance, it is believed that they are generally present in the discharges, not only during the height of the disease, but also, though to a less extent, at its commencement and for a considerable time during convalescence. The appearance of the bacilli in the urine is usually later than in the fæces. The experience thus far obtained seems to indicate that the bacilli may be obtained from about fifty per cent. of all cases on the first examination, and from about ninety per cent. after repeated examinations. The health board hopes that these examinations will prove of value, not only for diagnostic purposes, but also in solving important sanitary questions relating to the presence in and time of disappearance of the bacilli from the stools during convalescence.

"Physicians are requested to send specimens of intestinal discharges and urine from well-defined cases of typhoid fever, and also from all doubtful cases in which the Widal test has failed to give definite information.

"It must be understood that as yet these investigations are largely experimental, but that when the typhoid bacilli are isolated in culture an absolute diagnosis of typhoid infection is obtained.

"Directions for Preparing Specimens of Fæces or Urine for Examination.—Care should be taken to send, if possible, a specimen obtained from a natural

movement or one following a simple enema. No disinfectants, of course, should be employed. If the movement is formed, the portion from the part last passed—that is, the portion coming from highest up in the intestine—should be selected. In cases complicated by colitis, care should be observed to avoid, if possible, the selection of a specimen composed largely of mucus.

"The specimen is collected by seizing a small portion of the discharges between the two slips of wood accompanying the outfit, and placing this in a bottle. The top of the bottle is replaced and the specimen returned to a culture station or to the laboratory.

"Specimens of urine should be received directly into the bottle accompanying the outfit, or should be collected in an absolutely clean vessel and immediately transferred to this bottle, which is then returned to a culture station or to the laboratory.

"The necessary outfits, with directions and blanks, may be obtained at the various health-department depots, where diphtheria culture tubes, antitoxin, and other products are supplied. The accompanying blank should be fully filled out in every case."

SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

Tenth Annual Meeting, Held at St. Louis, November 9, 10, and 11, 1897.

GEORGE BEN JOHNSTON, M.D., PRESIDENT.

First Day, Morning Session.

THE meeting was held at the Southern Hotel.

Gall Stones in their Relation to Cancer of the Gall Tract.—DR. A. L. REED, of Cincinnati, read the paper, which was based upon a report of four cases in which distinct gall-stone history had preceded the history of malignant disease. The diagnosis had been confirmed in all of them by exploratory incision, and in two of them by autopsy.

CASE I.—Woman, aged fifty-two. Had hepatic colic during five years preceding, associated with all of the usual gall-stone symptoms. During the preceding thirteen months pain in the right hypochondriac region had been constant. Within the preceding six weeks persistent jaundice had developed. Globular tumefaction was felt below the costal margin. Exploratory incision revealed primary carcinoma of gall bladder and gall tract with secondary development in the liver. Diagnosis confirmed by autopsy.

CASE II.—Male, aged sixty. Had gall stones for twenty years; confirmed by their frequent passage *per vias naturales*. Patient had undergone rapid emaciation, and during the preceding month pain had become constant. More latterly he became pronouncedly jaundiced. No physical symptoms could be detected. Exploratory incision revealed carcinoma of the gall bladder and gall ducts, with secondary nodules in the liver. A calculus was found in the common duct and disintegrated by needle puncture. Primary recovery with amelioration of all symptoms, followed by death four months later. No autopsy.

CASE III.—Woman, aged forty-five. Had had hepatic colic for several years. During the preceding six months she had been profoundly jaundiced. Lost flesh rapidly. Examination of the blood revealed marked cholæmia. There were no physical symptoms in the right hypogastrium. Exploratory incision revealed induration about the head of the gall bladder and common duct, to both of which the duodenum was firmly attached for a distance of several inches. Calculus could be felt within the common duct just within its orifice. This could not be dislodged by prudent pressure or disintegrated by needle. It was delivered by incision through the duodenum. Patient never rallied, but died within thirty-six hours after the operation. No autopsy.

CASE IV.—Man, aged fifty-two, constant drinker. Had severe attacks of hepatic pain during preceding fifteen years. Last attack was persistent and continued for over six weeks. In addition to the usual symptoms he had a vacillating temperature and sweats. Operation revealed empyema of the gall bladder with induration at its ductile end. The gall bladder was stitched to the abdominal incision and drained. Death a week later. Autopsy revealed carcinoma of the ducts at their juncture. Numerous small calculi were found in the hepatic duct well up in its main trunk and in a number of its twigs. Multiple abscesses were found in the liver substance.

These cases, the author said, had a suggestive significance and pointed to an etiological relationship. This was explained by the result of persistent irritation of the foreign bodies upon the mucous surfaces, inducing hypertrophy, cell proliferation, and, in the event of the existence of original tendencies to cancer of ante-natal origin, they induced rapid development of the malignant neoplasm.

DR. EDWIN RICKETTS, of Cincinnati, reported two interesting cases of cancer which he believed were due to gall stones. He said Courvoisier had found malignancy in seventy or eighty-four cases of gall stone; while Bradrowski had found forty cases of cancer.

DR. JOSEPH EASTMAN, of Indianapolis, reported a case which had come under his observation within the last two weeks, which confirmed the remarks of the essayist. He believed that cancer of the gall bladder and gall ducts, as in the uterine cervix, was often the outgrowth of prolonged localized irritation.

DR. JAMES T. JELKS, of Hot Springs, had seen cancer of the uterus unmistakably produced by gall-stone infection; hence the deductions of the paper, to urge operative interference in all cases to prevent carcinoma of the liver, were prudent.

DR. RUFUS B. HALL, of Cincinnati, expressed himself as being firmly convinced that the deductions drawn from the paper would be sustained by future work in this direction. Nine cases tabulated by him confirmed the deductions of the essayist. He cited one case.

DR. A. M. CARTLEDGE, of Louisville, said that in many cases presenting a history of the passage of gall stones the patient may have had beginning carcinoma of the ducts for two or three years previously. He indorsed the views of the essayist relative to operative interference in cases of gall stones.

DR. L. MCLANE TIFFANY, of Baltimore, thought the causative relation between gall stones and cancer was not yet well established; but that cancer was accompanied by gall stones and found frequently to exist was well known.

DR. THADDEUS A. REAMY, of Cincinnati, took a more conservative ground, and thought the association ought not to go on record to the effect that because gall stones are associated with cancer the abdomen of every man or woman having gall stones must be cut open lest he or she, as the case might be, might have cancer.

DR. REED re-emphasized the significance of the persistent coincidence of cancer in long-standing gall-stone cases. His own brief experience embraced cases in which there had been long-standing antecedent gall-stone history.

Disposal of the Stump in Appendicitis Operations was the title of a paper by DR. W. D. HAGGARD, JR., of Nashville, Tenn. The author considered

appendicitis pre-eminently a surgical affection. Surgical isolation of the infected appendix was as essential as the hygienic isolation of any of the infectious diseases. The more imperative and explicit operative indications were specified. The various methods of disposing of the stump by invagination were discussed, and the modification and technique employed by Van Hook, Dawbarn, McBurney, Murphy, and Morris were described. The ideal of all surgery was completeness: applied to the surgery of the appendix, it was total extirpation of the organ. He then described the following method practised by Deaver in suitable cases: After the appendix and meso-appendix are freed from adhesions, the cæcum is stripped of its contents and grasped between the fingers and thumb of the left hand, the appendix being held by forceps and cut off flush with the colon. The resulting peritoneal wound is united by continuous Lembert sutures, while the cæcum is still held securely with the left hand just as in a gun-shot or stab wound of the intestine. Sutures may be disposed in two layers, the first uniting the edges of the wound and the second approximating the peritoneal covering to the cæcum over it. This method is not applicable in cases in which the cæcum is bound down by adhesions preventing its delivery in the incision. It is necessary to prevent the escape of colon contents by accurate suturing of the cut ends.

Total excision of the appendix with closure of the hole in the head of the colon does away, first, with subsequent perforation of the stump under the ligature from infection in its own cavity; second, abscess of the wall of the cæcum from invagination of the infected stump; third, continuance of infected process from stricture in the stump between the distal ligature and the proximal opening of the appendix into the cæcum; fourth, imperfect invagination with incomplete drainage of the stump on account of the cæcal wall being thickened and stiffened with inflammatory exudate.

The author has employed this method with entire satisfaction in five cases.

Report of Four Cases of Abscess of the Uterus.—This paper was by Dr. George H. Noble, of Atlanta, Ga. The first case was one of puerperal origin, the operation being done at the end of the second week. There were a pus tube and abscess of the left ovary. The appendages on the right side were normal. After extensive adhesions of unilateral disease had been separated, an abscess of the fundus uteri about the size of an ordinary lemon was discoverd, which was excised, curetted, and cauterized with carbolic acid. The cavity extended from the median line to the stump of the appendages on the left, which was turned into it and fastened with sutures to prevent the formation of a dead space. A glass drain was dropped into Douglas' pouch after the abdominal cavity had been flushed. The woman made an uneventful recovery and had been well for two years without any pelvic disturbance. Three other similar cases were reported in detail by the author. The four cases showed what any surgeon would sometimes do for an aseptic uterus when given a chance. They also supported the view that it was not always necessary to extirpate the uterus in suppurative inflammation of its parenchyma, and that such operations should be confined to cases in which the uterus was thoroughly septic or riddled with abscesses.

Dr. A. M. Cartledge said the results following the method pursued by the essayist were better than those of hysterectomy for infected uterus complicating childbirth or abortion.

Dr. J. Wesley Bovee was pleased with the advanced position taken by the author of the paper. Gynæcologists had to fear, however, the future usefulness of the uterus if they followed this method. It might tend to the production of rupture of the organ.

Dr. James T. Crofford said that in cases of abscess of the uterine wall originating from the mucous membrane, if the cervix was kept dilated and the uterus, freed of everything with a curette, was thoroughly cleansed and packed with gauze, these abscesses would open into the endometrium, followed by relief in the majority of cases.

Dr. Richard Douglas said that he treated cases of infection following abortion or full-term labor by the Carossa method with decided benefit.

Dr. W. E. B. Davis said that uterine abscesses following either abortion or the puerperal state could be treated successfully by incision and drainage in a good proportion of cases, even though the abscesses might extend beyond the uterus. Illustrative cases in which this treatment was resorted to were cited.

Dr. J. G. Earnest favored an exploratory incision to ascertain whether or not the patient was a fit subject for the method of treatment pursued by Dr. Noble. In the event the case was not suitable for the application of this method, very little damage was done by such an incision.

Dr. R. M. Cunningham said it was extremely difficult in general surgery to get primary union after curetting and disinfecting abscesses, in that it was difficult to destroy the staphylococcus, and more particularly the streptococcus, which perhaps extended beyond the abscess wall and continued its infective influence.

Dr. Noble, in closing, emphasized the point that the uterus was the seat of infection, and not the appendages. Only in cases in which there were one or two or possibly three abscesses was this method of treatment applicable.

A Study of Retroperitoneal Neoplasms and Suppurations, with Special Reference to Diagnosis.—Dr. Richard Douglas, of Nashville, Tenn., the author, accepted the definition of Mr. Lockwood for retroperitoneal neoplasm, namely, a solid or cystic tumor growing behind the peritoneum into the fold and not connected with any of the great retroperitoneal organs. The author then dwelt at length upon the pathology of these neoplasms and their causation, and then passed on to consider retroperitoneal cysts, and cysts of the pancreas. While not an advocate of the use of the aspirator in intra-abdominal diagnosis, yet under proper conditions the author thought this instrument would reveal valuable evidence, not only as to whether the growth was solid or cystic, but as to its nature. In retroperitoneal sarcoma aspiration revealed only a little blood or blood serum in the needle. This sign enabled Weir and Bull correctly to diagnosticate a case reported by Devlin.

Tubal and Ovarian Hemorrhage Resembling Ruptured Ectopic Pregnancy.—This paper was read by Dr. J. Wesley Bovee, of Washington, D. C. The author said that a few years back pelvic hæmatocele was a condition that every practitioner met occasionally, and many were the supposed causes of it. When the subject of ruptured tubal pregnancy was so universally taken up, some of the most aggressive investigators told us to search in every case of pelvic hæmatocele and we would find a ruptured ectopic pregnancy. This dictum, though not indorsed by all observers, found a ready following, and to this time the majority of students of diseases of the female pelvic organs had accepted it. Many cases had been reported in which a presumptive diagnosis of ruptured tubal pregnancy had been made—cases in which such symptoms as shock, sharp pain, irregularity of menstruation even to amenorrhœa, small tumor in the pelvis were present and some in which even death resulted, and yet autopsy had revealed no pregnancy, but instead hemorrhage from a Fallopian tube or an ovary, or both. The speaker offered, as he thought, conclusive evidence

against the positive statements that had gone out, that this condition would always be found in these hemorrhages. There were many instances in which women were deeply wronged by these diagnoses. Oftentimes the hemorrhages have occurred in virgins at a very young age and in widows above reproach. These hemorrhages result from ectopic pregnancy; from malignant disease of the uterus, appendages, or rectum; from varicose veins in the broad ligaments; from disease of the appendix; from inflammatory disease of the tubes and ovaries, and from many other causes. The author's remarks were restricted to disease of the appendages, and he cited a case in detail to exemplify them.

First Day—Afternoon Session.

Extra-Uterine Pregnancy Operated on at the Seventh Month.—Dr. J. G. Earnest, of Atlanta, Ga., reported an interesting case. The patient was thirty-six years of age, and the mother of several children. She came under his care September 19, 1897. Five months previous he had been called to see her on account of profound collapse which threatened life. A history of irregular uterine hemorrhages was elicited and a diagnosis of ruptured tubal pregnancy on the left side was made. Operation was deferred at this time, for the reason that it was feared the patient would die under the anæsthetic. Nothing further was heard from patient until the date mentioned, when the abdomen was found distended by a tumor on the left side and in the centre as high as the umbilicus. On the right side was another apparently distinct cyst filling that side of the pelvis and extending well up into the abdomen. On opening the abdomen a large tumor occupying the centre and left side presented a surface somewhat irregular, very dark in color, and traversed in every direction by large blood-vessels on the surface. The enlarged uterus was inclosed in this mass. The tumor of the right side was about the size of an adult head, about one-quarter of an inch thick, and seemed to be distinct from the large one, the dividing line dipping down between them about half the diameter of the tumor. To the larger mass were attached several coils of intestine, which were dark and changed in texture at the points of contact. The cyst on the right side peeled out without much hemorrhage, but with the work of peeling off the placenta from the pelvic and abdominal wall began the flow of blood so appalling. The task being pushed as rapidly as possible, the mass was loosened and iodoform gauze quickly packed behind it. The cyst was still unbroken and had the appearance when lifted up of being a fibrocystic tumor of the uterus. The author concluded to remove the uterus and drain through the vagina. As the uterine arteries could not be reached, a wire attached to a serre-nœud was thrown around the uterine body, tightened, and the mass cut away. The patient was now in such a critical condition that the author abandoned draining through the vagina. He tied the uterine and ovarian arteries, and packed the cavity with iodoform gauze, which was brought out at the lower angle of the wound, and closed the abdomen with silkworm gut. The gauze was removed on the sixth day. On the eighth day fæcal matter passed from the drainage tract. From this time until she left the hospital, October 30th, most of the fæces passed by the fistula. Five days later she was having free rectal evacuations with a corresponding falling off of the fæcal discharge from the fistula. The speaker said that if the fistula failed to close spontaneously it would be closed by operation. The large tumor was covered entirely by an enormously expanded placenta beginning in the bottom of the pelvis, firmly attached to the pelvic and a portion of the abdominal wall, its villi reaching well down into the tissues. From the top it was deflected from the abdominal parietes over beyond the centre, everting the body of the uterus. In the cyst thus formed was found a fœtus of about seven months.

Cystic Disease of the Mamma.—Dr. L. McLane Tiffany, of Baltimore, read the paper. He said the occurrence of cysts as a confusing element in the course of solid tumors of the breast was not so uncommon and might greatly resemble the subject dealt with in his paper; yet the clinical history and anatomy of cystic adenomata were sufficiently clear and the prognosis was sufficiently important to justify careful study. In most cases an accurate diagnosis could be reached before operation. Dr. Tiffany reported eleven cases that showed many symptoms in common.

Cystic Fibro-Adenoma of the Breast.—The speaker had examined three of these tumors, and, as they agreed so closely both in microscopic and macroscopic appearances, a description of one would answer for all. Macroscopically the breast is full and hard with numerous small nodules, to be felt under the skin, but not adherent to it. These nodules vary in size from that of a pea to that of a walnut. Some of them feel as though they contain fluid. When the breast is cut through, normal glandular tissue is seen to be replaced by a hard, dense white tissue with innumerable cysts containing either glazy sticky fluid or a cheesy material. The fluid varies in color. In some cases it is white and transparent; in others green, red, yellow, or a dirty brown. Microscopically sections were taken from various parts of the tumor, hardened in a ten-per-cent. solution of formalin for twenty-four hours and in alcohol. They were embedded in celloidin and stained by the ordinary method with hæmatoxylon and eosin. Under the microscope the sections presented the following appearance: There is a mass of white fibrous tissue including cysts, fat, and tubules. The tubules are lined by several rows of cuboidal epithelial cells and are massed in discrete areas presenting somewhat the appearance of an intracanalicular growth. In some localities the tubules are seen to be much dilated in parts, completely filled with cells, while outside they are surrounded by a well-marked area of round-cell infiltration. Here and there in the tubules are to be seen loose desquamated cells, which are granular and swollen, presenting somewhat the appearance of the cells of sebaceous glands. These cells have very deep-staining nuclei, and when seen in the smaller tubules are deeply pigmented, of a brownish color, as though blood stained, and, as here and there one can find the remains of red blood corpuscles, this is probably the case. Many of the ducts are lined by papillary ingrowths made up of cylindrical cells which take eosin well. The tubules present all stages of dilatation up to large cysts; many of the cysts are lined by several layers of cells resembling pavement epithelium. The fibrous tissue which is so abundant is rather wavy, not very cellular, and well supplied with blood-vessels. It stains very faintly with eosin. The diagnosis of benign cystic fibro-adenoma is perfectly clear.

The X-Ray and its Application to Surgery.—Dr. A. V. L. Brokaw, of St. Louis, Mo., made some remarks on this subject, and exhibited two hundred radiographs. He showed excellent radiographs of the heart, the thorax, fractures of the dorso-lumbar vertebræ, the pelvis, and fractures and lesions of the long bones. Of the many hundred exposures he had made, he had yet to see harmful effects following the use of the *x*-ray, such as cutaneous burns, loss of hair, and lesions of varying intensity.

Second Day—Morning Session.

Chronic Proctitis.—Dr. D. F. Talley, of Birmingham, Ala., read a paper on this subject. He dealt

with two varieties of non-specific chronic proctitis. First, those cases in which a diffuse, persistent inflammation, superficial ulceration, and papillomatous vegetation were the prominent features. Second, those in which the submucous tissues were principally involved in the hypertrophic process, causing a proliferative stenosing proctitis. The main symptoms of these two forms of proctitis were described. Rest in the recumbent position was recommended as being of paramount importance in the treatment of the first form of the disease. The diet should be of a liquid character, bland and nutritious. The sphincter muscle should be divulsed when the trouble is low in the rectum. In the absence of ulceration, when there was a diffuse chronic inflammation, the mucous membrane should be mopped with silver or copper of the strength of thirty grains to the ounce. The after-treatment consisted in putting the patient to bed, washing the rectum daily with warm boric-acid solution, and the use of suppositories of iodoform and boric acid. In chronic cases in which the ulcers were extremely indolent, the solid stick of silver or crystal of copper might be used. In these cases it was necessary to make repeated applications before the ulcers became healthy and began to heal.

The Sources and Diagnosis of Pyuria. — Dr. Howard A. Kelly, of Baltimore, read this paper. He began by stating that if he were asked what subject in the entire range of medicine and surgery he considered it most important to bring prominently before the profession at present he would probably reply, Pyuria. The subject is important on account of the great number of undetermined cases under treatment, and on account of the progressive nature of some forms of the disease, as well as on account of the facility with which the diagnosis can now be made with better means of investigation. Pyuria, of course, signifies merely the presence of pus in the urine; this may be in large or in small quantities, and may proceed from any part of the urinary tract from the external urethral orifice up to the cortex of the kidneys. The investigation of a pyuria is an analytical one—taking the symptom and trying to trace its origin. The best way to investigate a pyuria is to begin by making an examination of the urinary tract, following an anatomical order, proceeding from below upward. The history of the case, the microscopical and bacteriological and chemical examinations of the urine must be carefully made, and all facts ascertainable by palpation must be elicited first. The direct investigation then proceeds in an orderly manner, beginning with the external urethral orifice, where Skene's glands may be distended with a drop or two of pus; the urethra may be in a state of intense inflammation and even ulceration, affording sufficient pus to yield a decided sediment in the urine. Sometimes a suburethral abscess may pass unnoticed for many months, in spite of the fact that it contains from a teaspoonful to a tablespoonful of pus. The vesical sources of pyuria are from a cystitis, including a trigonitis or inflammation of the trigonum; foreign bodies, creating a cystitis; ulcers, associated with a cystitis or tuberculous in their nature. These affections will all be readily recognized by making a cystoscopic examination of the patient in the knee-breast position, through a simple cylindrical speculum. By this examination the cystitis will often be found to be well localized and in patches, which may be readily treated by direct topical applications; upon removing a foreign body, the cause of a cystitis, the pyuria disappears. Ulcers seen through the cystoscope may be treated with strong solutions of nitrate of silver, curetted, or cauterized. There are also a number of extra sources of pyuria, and these arise most frequently from tubal and ovarian abscesses breaking into the bladder, across the base of a broad ligament. If the pyuria does not come from the lower urinary tract it must then come from one of the ureters or kidneys; a telltale blush around a ureteral orifice often marks the side from which the pus issues. The author has found pyurias from the upper urinary tract proceeding from strictures of the ureter with a gonorrhœal, tuberculous, or other infection. The site of the stricture and the source of the pyuria may be readily located in these cases by passing a ureteral catheter—a metal one for the low strictures, or a flexible one for those above the pelvic brim. Renal pyurias are, after all, the commonest of all, and the author finds that these are most frequently caused either by a calculus in the pelvis of the kidney, or by a tuberculous pyelitis, or by a hydronephrosis which has become infected. Such pyurias are often the occasion of large amounts of pus in the urine, appearing either continuously or intermittently. By passing a renal catheter well up into the pelvis of the kidney, the pus may be evacuated and the pelvis washed out. If the pus is too thick to flow through the catheter, it may be thinned out by injecting a little fluid. By making an orderly investigation of this sort the pus is traced to its origin, and the source of the disease is discovered and treated and the cause eliminated, if possible, just as we would seek to investigate the source of the contamination of a body of water by taking a boat and travelling up the muddy stream until we had located the point at which it entered the main body and until we found that above this point the water was free from contamination. The methods proposed are safe in careful, practised hands.

The Early Diagnosis and Treatment of Cancer of the Uterus.—Dr. William H. Myers, of Fort Wayne, Ind., followed with a paper on this subject, in which he first dwelt upon the various theories respecting the nature of cancer, the last theory being that the disease was in its origin purely local. The author dealt with the elements of diagnosis, and gave statistical results following operations by different investigators of this disease. He considered the value of the microscope as an aid in the clinical diagnosis of cancer to have been overestimated, and cited several high authorities in support of his view. He closed by saying that the knife had become the emblem of gynæcological treatment. It had supplanted the curette, intra-uterine injections, caustic applications, the quaint conceits of the monkish craft, and the brutal records of the "cancer cure." The knife had become, in a surgical sense, the specific therapy of this particular disease.

Second Day—Afternoon Session.

A Case of Tetanus following a Surgical Operation.—Dr. F. D. Thompson, of Fort Worth, Tex., reported the case. The patient, a male, was twenty-one years of age, American, with good family history, for whom a radical operation was performed for extensive varicocele. Thorough asepsis was carried out. The result of the operation was excellent; yet on the morning of the ninth day after operative interference the patient could not open his mouth very well, and there was more or less stiffness about the muscles of the neck. A diagnosis of incipient tetanus was made, and the patient died in less than three days after the first appearance of the tetanic symptoms. The speaker could not account for the infection of this patient with the bacillus tetani.

At this juncture the president, Dr. George Ben Johnston, delivered his address. He selected for his subject—

The Prevalence of Specialism, and Who Shall be Specialists?—The tendency of the times was toward specialism in medicine. Specialism was desirable be-

cause it gave to the profession and the people the most intelligent consultants and the most skilled attendants the art of medicine could supply. He divided specialists into two kinds, the true and the pseudo-specialist. The former he defined as one specially distinguished for learning and skill in a given pursuit; the latter as one having merely a special occupation. He made very clear the difference between these varieties, for one reached the distinction of a specialist by reason of his training, experience, skill, and wisdom, whereas the other was made a specialist by the possession of a diploma, a doorplate and a "kit" of special instruments. The professional qualities of the true specialist he likened to a massive pyramid, the finished capstone of which constituted the specialty. This pyramid of experience, learning, and skill was a stable edifice, a pillar of strength which could not topple or reel. In the case of the pseudo-specialist this pyramid of learning was inverted. There was no base of a knowledge of detail, of general information, of professional attainments. The structure had no foundation in fact. It began with the specialty, and its growth spread as it ascended, overshadowing what was below, thus rendering it an unstable, top-heavy structure. The public had been improperly educated to the idea of specialism. In the public eye all specialists stood upon the same footing, possessing all the needful requirements to give the best service. The profession had misled the public and was responsible for this lack of discrimination on its part. Medical colleges should vigorously discourage the practice of recent graduates becoming specialists. Teachers should point out to them the error they were about to commit. They should counsel them. Colleges should recognize only the real specialists. Reform in the present system of specialism must be accomplished through the instrumentality of medical colleges and societies, and when they took the matter properly in hand the general profession and public would lend cordial support and the evil would perish.

Ovariotomy in the Aged.—Dr. A. M. Cartledge, of Louisville, Ky., read this paper. The patient upon whom the operation was performed was born October 29, 1816. Eighteen months before the speaker saw her an abdominal enlargement was noticed, followed shortly after by pressure symptoms. Latterly the gastric and digestive disturbances from pressure had been very troublesome. Emaciation and ovarian expression were appreciable, but not marked. Examination revealed the abdomen well filled with an encysted growth, which was diagnosticated as ovarian. Naturally the great age of the patient, eighty years seven months and fifteen days, made the decision as to operation a debatable one. However, an operation was deemed justifiable, urged, and consented to, and was done May 12, 1897. The ovarian cyst originated from the right ovary, was multilocular, and weighed about forty pounds with fluid and omentum. The operation was done in fourteen minutes. The patient sat up fourteen days after the operation, and left the infirmary on the seventeenth day thereafter. The author had operated seven times on women over sixty years.

Operative Treatment for Enlarged Prostate.—Dr. H. H. Grant, of Louisville, who contributed the paper, drew the following conclusions: (1) That in malignant disease any operative step except palliative suprapubic drainage, even if based on an error in diagnosis, is a serious mistake; (2) that in myomas, fibromas, and adenomas it is yet uncertain that good results will follow castration; and, furthermore, that such conditions render enucleation by the Alexander method very difficult and perhaps impracticable. Hence when interference resists catheterization and is not remedied by the permanent catheter, as suggested by Kane, suprapubic section with removal of the projecting portion, if practicable, or the permanent fistula of McGuire, is the wisest course. (3) In conditions including stone in the bladder, suppuration in the gland, and the suspicion of intravesical growths, exploration by the suprapubic method offers the best insight into the nature of the lesion, as well as the most hopeful prospect of relief. (4) Inasmuch as castration is unsatisfactory, and is less acceptable to men under sixty-five years of age than later, it appears that in the commonest form of enlargement, the chronic parenchymatous, to which the operation of Alexander is especially appropriate, will be best treated by this method, provided it appears practicable or necessary after section, which, if it bears out the promise of the present, will surely take a high place in the future, as the objections to it are almost *nil*, aside from the seeming gravity of the step.

Dr. James A. Goggans, of Alexander City, Ala., followed with remarks on empyema, and reported twenty cases.

Third Day—Morning Session.

Improved Technique in Operation for Intraligamentous Cyst.—Dr. Rufus B. Hall, of Cincinnati, after reviewing the literature on the subject, said he believed the mortality from operation for intraligamentous cyst was much higher than the statistics would lead one to believe. A large per cent. of the deaths were due to hemorrhage, either on the table or within a few hours after the patients were put to bed. He thought the operation proposed by him would save many lives, as it was practically bloodless. It was applicable to those cases in which the adhesions were very firm and the cyst could not be easily stripped from the pelvic floor. The operation he proposed is as follows: First tap the cyst and empty it. Ligate the ovarian artery on the tumor side at the pelvic border; ligate the ovarian artery on the opposite side, outside the healthy ovary; divide the broad ligament. Divide the peritoneum above the top of the bladder and push the bladder down. Ligate the uterine artery on the healthy side. Cut across the cervix and clamp or ligate the uterine artery on the tumor side. The blood supply is then cut off and the patient has not lost a drachm of blood. The capsule of the tumor can now be divided above the top of the bladder and at a suitable point behind, and the tumor enucleated from below upward with very much greater ease than from above downward, and with corresponding safety to the ureter, the rectum, and the iliac vessels. Close the peritoneum over the pelvic floor with a running suture of catgut. This method brings every part of the field of operation into view. The ureter can be seen, recognized, and pushed aside. The adhesions are separated along the line of cleavage instead of against it, as in the old method. Then followed the presentation of a specimen and the report of a case illustrating the operation and the class of cases to which it is especially applicable.

Dr. H. Tuholske, of St. Louis, read a lengthy and exhaustive paper on personal observations in abdominal surgery, in which he covered nearly every pathological condition known to the abdominal surgeon.

Symphyseotomy as Compared with Other Obstetric Operations.—This paper was read by Dr. George J. Engelmann, of St. Louis. The author illustrated his remarks by diagrammatic sketches. Symphyseotomy was not so attractive an operation as was Cæsarean section or the Porro operation, yet it was very successful as compared with the results of Cæsarean section. It was a successful all-around operation for the city and country. The mortality statistics of the different operations were given and compared. There

had been no trouble in union of the pubic bone after symphyseotomy. Quite a number of women had been delivered by a second symphyseotomy. There was no trouble in the locomotion of women so operated upon. A number of cases were on record of normal labors having followed symphyseotomy. The first symphyseotomy done in this country was by Dr. Williams, of Dennison, Tex. Dr. Engelmann showed what had been accomplished by symphyseotomy, and said that surgeons must be guided in a measure by that.

Plaster of Paris as a Universal Fracture Dressing was the title of a paper by Dr. John B. S. Davis, of Birmingham, Ala. The author said that less than three per cent. of the physicians who used plaster of Paris as a primary dressing cut the plaster at the time of applying it. The object of incising the plaster of Paris was to allow it to yield and at the same time fit the contour of the limb. For fractures of the shaft of the humerus, as elsewhere, he believed plaster of Paris was the best dressing.

The following officers were elected for the ensuing year: *President*, Dr. Richard Douglas, Nashville, Tenn.; *Vice-Presidents*, Dr. H. H. Mudd, of St. Louis, Mo., and Dr. James A. Goggans, Alexander City, Ala.; *Secretary*, Dr. W. E. B. Davis, Birmingham, Ala; *Treasurer*, Dr. A. M. Cartledge, Louisville, Ky.

Place of next meeting, Memphis, Tenn. Time, second Tuesday in November, 1898.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, November 18, 1897.

Edward G. Janeway, M.D., President.

Sanitary Science, the Medical Profession, and the Public.—Dr. Herman M. Biggs delivered the anniversary discourse, which was on the above topic. He said that while much had been done to reduce the mortality from preventable disease, fully one-third was still due to this cause. The importance of proper sanitation was well shown in 1892, by the deadening effect on commerce resulting from a knowledge that a few cases of Asiatic cholera had reached this harbor and that half a dozen cases had gotten into this city. Another example, fresh in our minds, was the yellow-fever epidemic in the South. An expenditure of one-tenth of the sum lost through the influence of this insignificant epidemic on the business of the country would be ample to render the introduction of yellow fever in the future wellnigh impossible. With all its terrors in the time preceding vaccination, smallpox was scarcely to be so much dreaded as was tuberculosis to-day. Tuberculosis is not dramatic in appearance or in course, and it is so familiar to all of us that but little attention is paid to it. It is on this account that its ravages still continue, yet no disease is better understood and none is more preventable by simple measures. After a careful and prolonged study of the subject, it was his deliberate conviction that the time was not far distant when, by proper sanitary supervision, the deaths from tuberculosis would be reduced to one-third the present rate. About two hundred years ago, of every thousand persons in the population of England, fifty to eighty died each year, and the average duration of life of each person born was not more than fifteen or eighteen years. How different from the present death-rate of seventeen per thousand! In contagious diseases we were as yet unable to adopt measures which would prevent a susceptible individual from contracting these diseases, but simple precautions would rob the communicable diseases of their terrors. Diphtheria had been increasing gradually in our large cities until the introduction of diphtheria antitoxin in 1894. Since then it had steadily diminished, until in Berlin the mortality had been reduced to one-fourth. Whooping-cough destroyed annually in New York City unnecessarily many hundred lives—more than were sacrificed by smallpox and cholera together. Great difficulty was experienced in controlling diseases of this kind in the tenement districts. Dr. Hill, of Birmingham, had shown in a very striking way how the ravages of scarlatina might be controlled by compulsory notification, and by the removal of such patients to the hospital. There had been many theoretical objections to this plan, but they had all been refuted by practical experience. Many of the victories of sanitary science, Dr. Biggs said, had been won through preaching and practising the gospel of cleanliness. The average annual death rate for the ten-year period ending 1893 was about twenty-six per one thousand of population, yet in the present year the death rate was a fraction over nineteen—a reduction of over twenty-five per cent. This was due to no special innovations, such as the introduction of an improved water supply, but to attention to many small matters and to the education of the people. Still it should not be believed that the limit had yet been reached; there was no inherent reason why the death rate in this city should not be reduced to fourteen per thousand, or even less, and the average duration of human life should be increased to fifty years or more.

The work done by the New York board of health was next considered more in detail. The speaker said that the health board had assumed that it was its duty to give such specific and general information regarding infectious diseases as could be furnished by a thoroughly equipped bacteriological laboratory. The board of health of New York had been the first to set this example, and, while it had been followed in many other cities, in no other place had the broad principle upon which this practice was founded been so liberally and consistently carried out. Medical practitioners sometimes forgot that the health board legislated for the whole city, and not for special sections or districts of the city, and that special legislation was generally objectionable. Much greater liberty was allowed in private houses than in tenements, because of the greatly diminished risk. It had always been the policy of the health officers not to interfere in private houses in matters that concerned the members of the family only, and which did not affect the outside public. The greatest cause of misunderstanding and complaint arose from the fact that, with but rare exceptions, physicians could not be induced carefully to read the circulars issued by the health department. He felt that, as a whole, the work of the health department in recent years had deserved and had received the commendation of the medical profession of the city. The interests of the individual and of the community were often apparently divergent, as in the restriction of noxious trades and the regulations affecting tenement houses. The primary object of the sanitary authorities was to secure for all proper air, light, water, and wholesome food. No other city in the world had a better and more wholesome water supply. It was true that at certain seasons of the year the water was unpleasant to the eye and to the taste, but this was due to suspended vegetable matter, which had not yet been shown to be deleterious to health. The greatest value of the system of compulsory notification of contagious diseases is that it allows the sanitary authorites to devise and carry out a scientific system of control. It did not seem to be very generally understood, even in the medical profession, that different diseases required different methods of control. The knowledge required for the intelligent discharge of the duties of a public-health officer must be broad,

exact, and entirely different from that obtainable in any existing institution. There are no men to be found in this country with an extensive knowledge of public medicine—not even in the large cities. The great sanitary need of the time is the establishment of training schools in public health, and that health officers should have diplomas representing the possession of an adequate knowledge of public medicine. The tenure of office should be longer and more secure, and the compensation should be large. In addition to this, there should be a national supervision, exercised by a properly constituted national board of health, the powers of which should be similar to those of the local government board of Great Britain. By such means we could hope in time to obtain more nearly ideal conditions throughout the whole country.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

A DEBATE ON TYPHOID—PROGRESS OF THE EPIDEMICS—BILHARZIA HÆMATOBIUM—SIR HENRY BURDETT, HIS SPEECH ON HOSPITALS, HIS CAREER—MR. HORSLEY—JUBILEE HOSPITAL AND "TRUTH."

London, November [illegible]

The Royal Medical and Chirurgical Society's next meeting is to be devoted to a discussion on the prevention of typhoid fever. This is very opportune, considering the serious epidemics which have recently occurred. The discussion is to be opened by Dr. Vivian Poore, and it may be anticipated that some of our leading authorities will join in it. If no new advance be made known, our present knowledge will at least be epitomized and a stimulus given to further efforts. I must add that the meeting will not be confined to fellows of the society, but visitors are cordially invited and will be introduced by the secretaries on the evening of the debate, which is fixed for the 23d of this month. As to the recent outbreaks a few facts of the week may be added.

Maidstone is still exciting the sympathy of the nation on account of its affliction, and large sums are being subscribed. It is hoped, however, that the worst has passed. At a meeting of the guardians yesterday it was decided to close the relief stations on Sunday next, except the central one. Four or five fresh cases of typhoid have occurred daily this week, bringing the total up to 1,828 with 129 deaths. It was reported further that diphtheria had been imported into one district, 28 cases having occurred.

At King's Lynn there has been a fall in the typhoid cases since Tuesday, from 14 to 15 daily down to 4 or 5. Yesterday the M. O. H. reported 5 as occurring in the previous twenty-four hours, making a total of 380, with 26 deaths. It is said, however, that the disease has spread beyond the town limits. Dr. St. George Mivart, the recently appointed government inspector, has been down to advise the authorities.

The Clifton outbreak has been traced to a definite cause, and the Bristol town council has been informed that there is no extension, but seven deaths have already occurred. From Belfast I hear of three more deaths in dangerous proximity to the water reservoirs.

At the Pathological Society meeting Mr. C. G. Seligmann exhibited some live ova of Bilharzia hæmatobium which he had obtained from the urine of a soldier recently returned from Mashonaland. These ova, he said, were constantly passed from both the bladder and rectum. Those from the bladder had terminal spines only, but those from the rectum had also lateral spines. He found the ova could be hatched in urine (a surprise for those who have pooh-poohed the fact), though not so quickly as in water of the same temperature. It is very interesting to watch the hatching and the amœba-like changes in the shape of the embryo.

Sir Henry Burdett has incurred the anger of many general practitioners by his speech at the meeting on hospital reform, in which he attributed a degree of incompetency to some of their body. Called to account for this by a subsequent speaker, he explained that he meant only that many would be greatly helped if they went to hospitals and attended post-graduate classes. This explanation does not amount to a repudiation of the sense in which his words were understood, and *The Lancet*, very naturally, defended the general practitioners from the insinuations of a non-medical man. Sir Henry retorts that he has passed all but the final, and if need be to defend his position he may devote a few months to passing and then challenge the editor to stand against him as candidate for the General Medical Council. This would be amusing as a novel sort of controversy on hospital abuse, and no one doubts but Sir Henry's energy would carry him far. Moreover, he is just retiring from the position he has so long held on the Stock Exchange, where, as secretary of the share and loan department, he has for years been a most important and hard-working person. That post was gained by his success in reorganizing the financial affairs of the Dreadnought Hospital, so that his whole life has been connected with hospital affairs, in which he has always displayed the keenest interest. I lately mentioned his "Hospitals and Charities," which occupies almost an official position. He is on the councils of the Prince of Wales' Fund, the Sunday Fund, and a number of hospitals. It is chiefly for his work of this kind that he received his K.C.B. He is the editor and proprietor of *The Hospital*, a journal devoted to management and nursing. He founded the Royal Nurses' Pension Fund, which is a very important organization, and has a finger in the pie of charities and hospitals too numerous to mention. It is easy, therefore, to see that, whatever his views, he is a man to be reckoned with. His knowledge of every sort of finance is in itself a power. He is no doubt conscious of this and perhaps a little too ready to force his opinions on others, but I think he is a good friend to hospitals and by no means unaware of the difficulties of professional life. Zeal and hasty speech often go together, and there may be no permanent cause of offence because Sir Henry's earnestness and self-consciousness led him to assert himself—and incidentally depreciate the qualified G. P. I do not suppose offence was intended, but the speech was unfortunate, and accentuates the objections which many feel to some of his views on hospital management. He is now about to publish a nursing-directory.

Professor Horsley's election to the medical council necessitated his resignation of the presidency of the Defence Union, since that body prosecutes before the council where Mr. Horsley will exercise judicial functions. One of the vice-presidents of the union, Dr. W. S. A. Griffith, succeeds Mr. Horsley, no easy task, and I hope he may be as successful.

Mr. Horsley has just been appointed by the crown as the successor of the late Mr. Walter Rivington in the senate of the University of London.

The war waged by *Truth* against the Jubilee Hospital is concluded, Mr. Labouchere having laid down his arms. It is rather an unexpected move for his paper, but since he so discredited himself before the African committee people are paying less attention to his *Truth*. The Jubilee Hospital does not gain the confidence of the profession. It is regarded as an unnecessary institution, and its very position shows that the neighborhood is not one from which patients should come.

THE TREATMENT OF SYMPTOMS.

To the Editor of the Medical Record.

Sir: Dr. Seth Mereness, in the Medical Record of October 16th, says that every physician knows that danger to life is not at all proportionate to severity of symptoms. I will assert that a large majority of deaths, except sudden deaths, are preceded by severe symptoms. I believe that every physician knows that a case of pneumonia with severe symptoms has a worse prognosis than one with mild symptoms. A mild case of pneumonia will destroy life in the aged, but it is loss of vitality more than the pneumonia that kills. If, as he says, it has never been demonstrated that combating symptoms ever contributed to or effected a cure, then nothing has ever been demonstrated, human experience is without value, and cause has no relation to effect.

I have seen the mortality of typhoid fever reduced to two per cent. by the judicious use of cathartics, antiseptics, and antipyretics. Baths may do as well, but the same objections must hold with this writer, for they combat symptoms—are given for that purpose, as the prognosis is improved thereby. Baths, however, cannot be used with the necessary thoroughness in private practice.

While the article contains much that is instructive, such doctrine here alluded to violates all the teaching I have ever seen in the Medical Record and contradicts the opinions of thousands of the most intelligent men of the age. I am certain that the relief of symptoms, whether by hygiene, hydrotherapy, drugs, or any other agency, generally effects improvement and tends to a cure. I am certain, too, that in hopeless cases the relief of symptom, by whatever means, gives great comfort, reduces suffering, and in many instances prolongs life. O. S. Ensign, M.D.

"WHAT MUST WE DO TO BE SAVED?"

[illegible] Editor of the Medical Record.

Sir: From the standpoint of a poor country physician, Dr. Hillis has greatly weakened what otherwise would have been an admirable paper—"What Must We Do to be Saved?"—by an uncalled-for and an unjustifiable attack on the government of the United States and by an equally unjustifiable attack on the rich. The latter, though embodied in a bit of beautiful rhetoric, is so grossly misleading that it should not be allowed to pass without a protest. F. Powers, M.D.

[illegible]

A MEDICAL MISSIONARY WANTED IN CEYLON.

[illegible] Editor of the Medical Record.

Sir: In connection with the Woman's Medical Mission in Jaffua, Ceylon, there is an opening for a lady doctor to be the associate of Dr. Isabella Curr, who went to Ceylon last year.

The five large new buildings of the Woman's Medical Mission, viz., the mission house, the nurses' training-school, the medical and surgical wards, and the dispensary, together with the necessary outbuildings, are completed and ready for use.

The wards provide accommodation for forty in-patients. The training-school will accommodate eighteen nurses and a matron.

Rev. T. B. Scott, M.D., and Mrs. T. B. Scott, M.D., who are in charge of the general medical mission near by, will act as consulting physicians.

A population of three hundred thousand people in this province is accessible. The climate is healthful. The outlook for the work is promising. Ten families of American and British missionaries reside in the province. There are three thousand native Christians, members of mission churches, and fifteen thousand children and youths in mission schools.

As the training of educated Christian young women as nurses will be an important feature of the work, we are desirious of finding, to fill this vacancy, a medical lady who has had a nurse's training, or one who would be willing, before going out, to take some special instruction in nursing. She should be possessed of a true missionary spirit. We should be glad to hear from any one who is fully qualified, or who is about to graduate the coming spring.

Mary and Margaret W. Leitch.

THE IMPROVEMENT OF GENERAL ANÆSTHESIA.

To the Editor of the Medical Record.

Sir: Since my return to the city on September 15, 1897, the time of commencing my fall service at the German Hospital, I have in all operations requiring general narcosis made use of the anæsthetic mixture proposed by Dr. C. L. Schleich, of Berlin, in 1895, and strongly recommended by him again this year. I have availed myself of the advantages of this mixture also in all my private operations done during this period.

I have been personally so favorably impressed with the working of the new mixture, as have also been the members of the house staff of the German Hospital and all those colleagues who witnessed my operations in hospital and private practice, that I almost feel it my duty to give this preliminary report, which is based on very nearly one hundred cases of my own—certainly a sufficiently large number to permit drawing conclusions. More patients than the comparatively few coming under the care of a single man should derive the benefits of this anæsthetic as soon as possible. I am convinced that whoever has tried Schleich's anæsthetic mixture will not return to the ordinary ether or chloroform narcosis.

Schleich seems to have solved the problem of making general anæsthesia a safe procedure—as far as this ever can be done—by experimenting on a physical, not on a chemical basis; viz., by adapting the boiling-point of the narcotic to the temperature of the body.

He uses a mixture of three drugs, viz., chloroform, ether, and petroleum ether (benzin), the latter of the boiling-point of 60°–65° C. (140°–148° F.).

Formula I. Boiling-point = 100.4° F. (38° C.).—Chloroform, 45 c.c. = 1½ oz.; petroleum ether, 15 c.c. = ½ oz.; sulphuric ether, 180 c.c. = 6 oz. It is used for narcosis in operations of short duration.

Formula II. Boiling-point = 104° F. (40° C.).—Chloroform, 45 c.c. = 1½ oz.; petroleum ether, 15 c.c. = ½ oz.; sulphuric ether, 150 c.c. = 5 oz. It is used for operations lasting a little longer.

Formula III. Boiling-point = 107.6° F. (42° C.).—Chloroform, 30 c.c. = 1 oz.; petroleum ether, 15 c.c. = ½ oz.; sulphuric ether, 80 c.c. = 2⅔ oz. It is used for major operations.

The measurement is made by volume, not by weight. In a chemical sense it is a real solution. Petroleum ether of the required boiling-point, 140°–148° F., can be had of any first-class chemist. Personally I obtained my specimens from Charles Cooper & Co., of this city. I have induced a number of druggists throughout the city to keep a stock of this ether.

Schleich recommends a special mask for the administration of his mixture. Up to date I have used, to my entire satisfaction, the ordinary ether mask (paper

and towel); often also that used for chloroform anæsthesia. A few days ago I received Schleich's mask from Berlin, and shall now test the merits claimed for the same.

The improvement of the anæsthesia with the help of this mixture is very great in my opinion. I shall here mention only a few points:

We miss the frequently occurring cyanosis, the salivation, the accumulation of mucus in the trachea during the administration of the anæsthetic (ether); we do not meet with bronchitis or broncho-pneumonia afterward. As compared with chloroform, the influence of the mixture upon the heart's action is by far less marked; we have given it repeatedly in cases of heart disease. There are a great many other advantages, to enumerate which here would lead me too far. In a paper to be read before the next meeting of the New York County Medical Society, on December 27th, I shall give a detailed report of my experience.

WILLY MEYER, M.D.

November 26, 1897.

FINES FOR ILLEGAL PRACTICES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The New York *Sun* of November 17, 1897, noticing the fine of $150 imposed on Finney, a druggist, for illegally practising medicine, said: "This is the heaviest fine yet imposed in special sessions for this offence."

In making this statement *The Sun* was misinformed. The heaviest fine imposed since the County Society began to inforce the medical law in 1881 was that of $500, inflicted on January 9, 1889, in special sessions, upon one Bourquteet, "private physician to the Bey of Tunis," for a first offence. That same court also imposed fines of $250 upon Brown, August 12, 1887; Strosser, June 4, 1891; Goldsmith, October 31, 1892; and De Samora, December 8, 1892; also fines of $200 upon Eckardt twice; Kraft, Tochterman, Montague, Utzsinger, Michael, Morrel, La Roche, St. Leon, and Raffel; also fines of $150 upon Weinstein, Guggenheim, Libertino, Hamecher, Pool, Koehler, and Rosa. Thus there have been twenty-three cases in which a fine of $150 or more has been imposed by that court.

The court of special sessions also imposed on October 4, 1897, prior to Finney's case, a fine of $150 for the illegal practice of dentistry by one Diaz in the "Boston Dental Parlors," and in so doing expressed approval of the dental law and the judicious manner in which the State Dental Society sought to have it inforced. This the MEDICAL RECORD noted, I think, at the time.

The largest fines inflicted under the dental act have been two of $500 each upon the notorious Kahn and Jordan, whom the State Dental Society caused to be convicted in 1896 for unlawfully affixing the letters M.D. to their names.

All of the above fines, except those in the dental cases, were imposed prior to December 15, 1893; and it may therefore be possible that no fine of $150 has been imposed in special sessions since then.

The last report of counsel published by the County Society, that of 1896, shows by a tabulation that since December 15, 1893, five fines of $250 and one of $150 have been imposed, but in what court does not appear: however, from what is said of the court of special sessions in the body of that report, and the further fact that *The Sun* presumably derived its statement from some one it supposed was authority, one may fairly assume that those fines were imposed in general sessions.

It is a curious result of the various amendments of the laws that—dentistry and the practice of medicine being both regulated by chapter 5 of the general laws, and the former being a specialty of the latter—the misdemeanor of unlawful dental practice must be punished by a fine of not less than $50, and may be punished by a fine of $500; while the offence of unlicensed medical practice cannot be punished by a fine of more than $250, and may be punished by as small a fine as the court sees fit to impose, which in one instance was $10 and in three cases $25. Thus for purposes of punishment, assuming dentistry to be a specialty of medicine, the part is greater than the whole—Aristotle to the contrary notwithstanding.

W. A. PURRINGTON, M.D.

"SHOULD MINISTERS PAY DOCTORS?"

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In answer to the query, "Should Ministers Pay Doctors?" I say, "Ay, verily." For twenty-five years your humble servant has been pouring physic down and pumping other medicines up into the ministers, their wives, and other members of the family, free of charge and sometimes without even a thank you. Why should we do it? Are not the ministers as well paid, as well fed and clothed—house rent very little, and often free? When they travel, 'tis either D.H. or half-fare.

Don't we pay them when they marry us? Don't we tip them when they baptize our children? Don't we give them a few ducats when we die?

They do not have the expense of keeping a horse or two, nor of the wear and tear of carriages, cutters, harness, etc. No getting up "o' nights" for a drive of forty miles in the country, with the wind howling at a speed of forty miles an hour and the mercury forty below zero—furnish the medicine free—all for the love of your fellow-man. Not a cent in sight, but we must go—*bon gré, mal gré*—or we are heartless, cold-blooded, cruel.

Ministers sometimes show their gratitude, as when I attended one through a severe sickness, and during his convalescence he advised one of my good pay patients to try a rival M.D.; said he would "get him on his legs quicker." This minister, however, was an exceptionally mean one. As a rule, they are jolly good fellows; but I say, let them pay and then they will better appreciate us.

H. R. PORTER, M.D.

[illegible] N. D., November 15, 1897.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 27, 1897:

	Cases.	Deaths.
Tuberculosis	102	57
Typhoid fever	26	5
Scarlet fever	127	6
Cerebro-spinal meningitis	0	3
Measles	227	1
Diphtheria	103	15
Laryngeal diphtheria (croup)	7	2
Chicken-pox	21	

Bacteria in Ink.—Septicæmia following a pen scratch is explained by Marpmann, of Leipzig, on the theory of the constant presence in most inks of saprophytes, bacteria, and micrococci. A bacillus was cultivated and found fatal to mice.

A MODIFIED INCISION AT THE OUTER BORDER OF THE RECTUS MUSCLE FOR APPENDICITIS.

BY FRED. KAMMERER, M.D.,

AT the meeting of the New York Surgical Society on March 24, 1897,[1] I showed two patients upon whom I had operated for appendicitis in the declining stage of an acute attack by a method the principle of which as applied to appendicectomy was, I think, new. Since then I have had occasion to operate in only two other cases, both during the interval, by the same method.

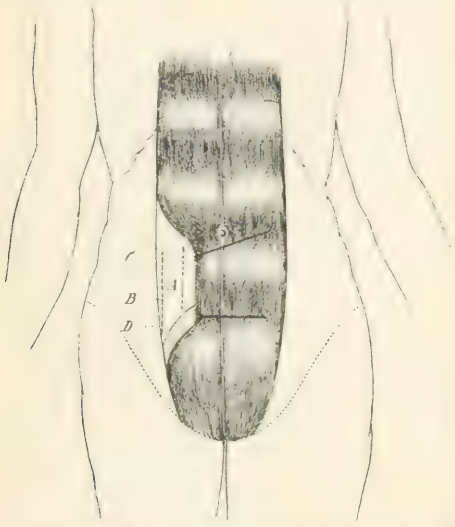
There can be no question that even very small incisions, carried in one plane through the entire abdominal wall, will occasionally lead to the formation of hernia later on. The size of the incision through the skin is irrelevant in this respect. The damage to the muscular tissues and fasciæ is responsible for the later development of a hernia, and it is well to remember in this connection that a good deal of damage can be done to the same even through a skin incision of only one or two inches. Herniæ were of frequent occurrence after operations for appendicitis when the old incision at the outer border of the rectus muscle was universally practised, before McBurney published his method of intermuscular separations. My own experience with this method is limited to a few cases, but we may gather from the reports of others that it has taught us to avoid herniæ with almost absolute certainty. To-day I believe that the same assertion can be made of the modified incision at the outer border of the rectus which I demonstrated at the meeting above referred to. I have now operated six times according to this plan. Two of the patients were operated upon in the summer of 1895. In one case suppuration occured, and although, after some delay, the patient was discharged with his wound closed, the integrity of the abdominal wall may have become impaired. In the other case the wound healed by first intention, but I have not been able at present, after a lapse of two years, to find the patient again, although I have made diligent search for him. The other four cases have come under my observation this year, and seem to hold out promise of permanent restoration of the abdominal wall with very little disfiguration. The method and the cases are the following:

Method.—Before administering the anæsthetic the patient is requested to raise his body from the operating-table; in other words, to contract his recti muscles, so that the outer border of the right rectus may be accurately determined. I have found a very marked difference in the width of this muscle in different individuals, and in making only a small incision in the skin it is essential to locate the outer border at the correct place. The incision should be about two inches in length, and the line drawn from the superior anterior spine to the umbilicus should divide it in such a way that somewhat more of it lies below than above that line. The skin, subcutaneous fat, and aponeurosis of the external oblique are divided. The anterior sheath of the rectus muscle is now opened, the operator cutting in the same direction a little to the inside of the right linea semilunaris and exposing the upper and outer border of the rectus muscle itself. It is important not to place this incision too far in an outward direction, in order not to incise the linea semilunaris and thus impair the strength of the abdominal wall. The rectus muscle is now drawn toward the median line and dissected away from its posterior sheath for about one inch or a little less. In doing this we come in contact with the epigastric vessels and a branch of the ileo-hypogastric nerve, which latter perforates the sheath and passes into the rectus muscle, generally in the upper half of the incision. Ligation and division of the vessels may be practised, if the latter are at all in the way. I do not see any disadvantage in such a course, as we often ligate vessels of the same size in other operations without the slightest hesitation. Section of the branch of the ileo-hypogastric nerve is, however, a more serious matter. In the first two cases reported below I divided the nerve. The result of this was atrophy of that part of the rectus muscle which is supplied by it. Five or six weeks after the operation a very marked wasting of the muscle was apparent when the patients called into action both their recti. The atrophy was confined to only a small part of the muscle, lying very likely between the two nearest tendinous intersections of the latter, immediately below and to the right of the umbilicus. No other portions of the muscle were involved, they being evidently supplied by other branches, such as the anterior branches of the lower intercostal nerves. In my last two cases I have, therefore, avoided section of the nerve. This is easily accomplished by hooking it with a blunt curved retractor and pulling it into the upper angle of the incision. The dissection of the muscle from its posterior sheath is the work of a few moments, and is more easily accomplished when the abdominal walls are tense than when we are dealing with lax and flabby abdominal muscles. The rectus muscle is now drawn well toward the median line by the aid of two sharp retractors, and an incision (*C*) is carried through the posterior sheath, the transverse fascia, and the peritoneum, parallel to the original incision and a little shorter than the same (about one and a half inches long). The cut edge of the peritoneum toward the median line is secured by the application of one or two artery clamps. The flap of peritoneum, fascia, and sheath (*A*), on the outside edge of the peritoneal incision, is relieved of all tension as soon as the abdominal cavity is opened, and when a blunt retractor is inserted into the incision and traction made in an outward direction, to expose the region of the appendix, it offers very little, if any, additional resistance to that of the entire abdominal wall at the site of the original incision through the skin (*B*). This is a point I wish to emphasize, as the discussion, following the presentation of my patients at the meeting I have previously referred to, made it apparent that some of the gentlemen present were in-

[1] Annals of Surgery, August, 1897, vol. xxvi.

clined to the belief that the site of the incision might be too near the median line. As already stated, I cannot find that this overhanging flap of sheath, fascia, and peritoneum (*A*) offers any further obstacle to exposure of the region of the appendix than is met with when the incision is carried at the outer border of the rectus straight into the abdominal cavity. The question is simply whether or not the outer border of the rectus is a convenient location for entering the abdomen and searching for the appendix. I believe it is as good as any. No particular location can be the best in every case.

After the appendix has been found and removed, the incision through the posterior sheath, fascia, and peritoneum is closed by a running catgut suture (I use formalin catgut), to accomplish which the rectus must be drawn well aside. Thereupon the latter is released from the retractors and, falling into place, is fastened by a few thin catgut sutures at its outer edge



A, Layer of posterior sheath of rectus, transversalis fascia, and peritoneum.
B, Incision through the same.
C, Incision through posterior sheath of rectus, fascia, and peritoneum.
D, Semilunar fold of Douglas.

in its original situation. The incision in the anterior sheath of the muscle is now closed by individual sutures of catgut, and finally the aponeurosis of the external oblique and the skin are dealt with in the same manner, separately.

Cases.—I omit the first two cases, operated upon during the summer of 1895, as I have not been able to hunt up the patients this year, when I again took up the operation. I shall say, however, that I experienced no difficulty in finding and removing the appendix through the incision.

Case I.—G. H——, male, aged twenty-two years. First attack. Seen at the expiration of a week, with some resistance and pain on pressure still present in right iliac fossa; also a distinct infiltration on deep pressure.

Operation on January 20, 1897: Appendix bound down by adhesions, pointing in an upward and backward direction, its tip lying near posterior brim of pelvis. Adhesions broken up and appendix removed; small perforation found at tip. On section, extended gangrene of mucosa; two fæcal concretions in appendix. Suture as above described; primary union.

Case II.—J. S——, male, aged forty-two years. Recurrent appendicitis for past ten years; last attack about a week previous; very distinct induration in iliac region about one-fourth of an inch wide and one and one-half inches long, at outer border of rectus.

Operation on February 3, 1897: Appendix found lying very superficially, corresponding to infiltration felt before opening of abdominal cavity; easily removed; much swollen, not perforated, and containing no concretions; beginning gangrene of mucosa well marked at tip of appendix. Suture; primary union.

In the above two cases marked partial atrophy of the rectus muscle developed, as the result of section of the ileo-hypogastric branch. In the second case reported, which I had occasion to examine during September, I have, however, found complete restitution to normal size and activity, although no examination was made with electric currents. No hernia has developed from this partial temporary paralysis. Nevertheless, I think it wiser to avoid its occurrence, as in the following two cases:

Case III.—M. S——, female, married, aged twenty-seven years. Many attacks lately; last attack a few days ago, lasting only a day or two with tenderness at McBurney's point. At time of operation no physical signs, but slight pain on deep pressure.

Operation, end of March, 1897: Usual incision; rectus muscle very broad, its outer border only one inch from superior anterior spine; some difficulty experienced in dissecting away the posterior surface of the muscle from its sheath, owing to great laxity of muscular tissue. The incision, in this instance, having been unintentionally placed at a higher level, the branch of the ileo-hypogastric was found in the lower half of the incision, and it was therefore drawn into the lower angle of the wound by a blunt retractor and not divided. Ligation of epigastric vessels unnecessary; appendix three and one-half inches long, buried among intestines, slightly adherent, easily found and removed; its walls very much thickened; no perforation. Suture; primary union.

September 20, 1897: No indication of hernia; at cicatrix skin freely movable over subcutaneous tissues.

Case IV.—R. J——, male, aged seventeen years. About a dozen attacks during 1897, mostly mild in character, but a few accompanied by pain and high temperatures, necessitating rest in bed for several weeks; slight sensitiveness at McBurney's point on deep pressure; no physical signs.

Operation, September 10, 1897: Incision two inches long; muscle easily separated from sheath; nerve branch, across upper part of wound, easily held out of harm's way by retractor; appendix on inner side of colon, kinked and firmly adherent to its own mesentery; blunt separation of adhesions somewhat difficult during removal of appendix; end of appendix obliterated for about three-fourths of an inch, the remaining portion, to its base, much distended and filled with pus and two fæcal concretions; a tight stricture found at the base. Suture as usual; primary union.

Further Remarks.—In a number of dissections upon the cadaver I have found the semilunar fold of Douglas, which marks the inferior termination of the posterior sheath of the rectus muscle, at a distance of about one inch from the nearest point of the line drawn from the superior anterior spine to the umbilicus. (I have tried to demonstrate this in the figure, although at the operation the rectus is never displaced to such an extent as to disclose the semilunar fold.) It is very easy after removal of the rectus, with the abdomen unopened, to demonstrate the weakness of what remains of the abdominal wall between the semilunar fold and the symphysis by pressure upon the abdomen, which will cause a bulging of the intestines at that point. But even with due regard for these anatomical facts, I do-

not think that an incision carried beyond the semilunar fold can lead to the formation of hernia, if primary union is obtained and the rectus abdominis fully covers the sutured incision into the posterior sheath. On the other hand, there is no necessity for carrying the incision lower than the semilunar fold.

The modification of the incision at the outer border of the rectus is suited for cases during the interval. Although the first case reported was operated upon by this method, when the products of acute inflammation and perhaps the infectious agents themselves were still present in the tissues, and the case did well, I think it might have been wise to establish drainage, if only for a short period. But in that event I should have employed McBurney's incision for suppurative cases, an inch to the inside of the anterior superior spine. When suppuration is well established, I feel as if I would rather err on the safe side. In many such cases at the critical moment we need as large an opening as we can get for efficient drainage. I venture to believe that we all are, now and then, agreeably or disagreeably surprised at the condition of affairs revealed after abdominal section in cases of acute appendicitis. With this uncertainty I should hesitate to employ any other than a free incision in suppurative cases, although we have lately heard of splendid results even in such cases by McBurney's blunt dissection.

Some points in favor of the modified incision at the border of the rectus are the simplicity of the procedure, the possibility of doing the operation with one assistant, the technical advantage when operating on persons with well-developed abdominal muscles. I have practised the method without any blunt dissection, if that be worth mentioning.

NOTE.—A few days before receiving the proofsheets of this article, my attention was called to a short communication by Ad. Jalaguier, surgeon to the Hôpital Trousseau, in Paris, in which the author describes an operation very similar to the one I have just described. He further states that he has employed the same in some twelve cases with very satisfactory results. Whether or not his first operation was done before my own (summer, 1895) I cannot say, as he gives no details of his cases. Even if we have both employed the method independently of one another, I regret that I have been guilty of an oversight in reference to Jalaguier's publication. He divides the skin and the aponeurosis of the external oblique at the outer border of the rectus, and then dissects the aponeurosis on the inner side of this incision for some distance from the anterior sheath of the muscle. The latter (the sheath) is then divided about one centimetre to the inside of the border of the rectus, exposing the muscle. I have not insisted on this point, but simply divide the anterior sheath somewhat to the inside of the right linea semilunaris. In all other particulars the methods are exactly alike. As all the layers are finally sutured separately, the planes in which the lines of suture lie in Jalaguier's operation are more distant from one another than in mine. I think, however, that the main support is given to the abdominal wall by a firm union of the rectus muscle with the sutured incision in the posterior sheath. Jalaguier merely mentions the nerve branch passing within the line of incision into the rectus, and I assume that he has always been able to avoid cutting it. It is certainly entitled to the full attention of the surgeon. He has recommended the operation more especially in children with thin and pliant abdominal walls, and he prefers "*l'incision ancienne*" in adults with well-developed and rigid muscles. I rather like to operate by the method on patients with a well-marked rectus abdominis muscle.

Phimosis as a Factor in the Causation of Hernia.—It is said that inguinal hernia often arises in consequence of the straining efforts of the child. This may be true in some infants who have a patent processus vaginalis, but it certainly does not very often occur when these peritoneal prolongations have become obliterated; and, moreover, it must be freely admitted that a very large number of cases of aggravated phimosis are not the subjects of hernia. Thus, although the condition may play a part in the production of hernia, it is probably but rarely the sole factor.—ECCLES, *The Hospital*, April 24th.

THE CLINICAL VALUE AND CHEMICAL RESULTS OF USING PROFESSOR GAERTNER'S MOTHER MILK IN CHILDREN.

BY LOUIS FISCHER, M.D.,

PROFESSOR OF DISEASES OF CHILDREN IN NEW YORK CLINICAL SCHOOL OF MEDICINE; ATTENDING PHYSICIAN TO THE CHILDREN'S DEPARTMENT OF GERMAN DISPENSARY, TO THE WEST SIDE GERMAN DISPENSARY, TO THE MESSIAH HOME FOR CHILDREN, CONSULTING PHYSICIAN, DEPARTMENT OF CHILDREN, TO THE UNITED HEBREW CHARITIES,

AND

HERMAN POOLE, F.C.S.,

NEW YORK.

DURING the last two years a new infant food has been given great prominence in European medical literature. This new factor in the problem of infant feeding is the mother milk of Professor Gaertner, of the University of Vienna. Its *début* before the profession was made in an article by Gaertner in the *Therapeutische Wochenschrift*, May 5, 1895. A few months before, January, 1895, Gaertner, in an address before the Vienna Scientific Society, explained the mode of preparation and the results obtained with his new modification of cow's milk, for such the mother milk of Gaertner really is. Professor Gaertner, in the preparation of his food, has aimed to overcome what has been the great difficulty in infant feeding—namely, to reduce the excess of casein by a scientific process without the addition of chemicals.

To achieve this result he employs a machine called a separator or Pfanhauser centrifuge, which makes four thousand or eight thousand revolutions per minute. The apparatus consists essentially of a drum of steel, which revolves on its axis. This drum is filled with equal parts of fresh cow's milk and sterilized water. The mixture contains approximately the same amount of casein as human milk, for cow's milk undiluted contains about twice as much casein as human milk. The mixture is next poured into the centrifuge and the speed of the drum is carefully regulated, so as to separate the mixture contained therein into (1) a creamy (fatty) milk, and (2) a skimmed milk. The two portions so separated are then led off separately by suitable openings in the centrifuge.

The analysis of each of these portions shows that the creamy milk has the same quantity of fat as is found in human milk, while about two per cent. of the casein is contained in the skim milk, and the remainder, about 1.7 per cent., remains in the creamy milk. The chemical composition of fat milk is shown in the following table:

	Proteid.	Fat.	Sugar.	Ash.
Fat milk	1.76	3–3.5	2.5	0.35
Human milk	1.03	3.5	7.03	0.21
Cow's milk diluted with one-half water	1.76	1.6	2.5	0.35

If, now, three or four grams of milk sugar be added to every one hundred cubic centimetres of fat milk, the percentage of sugar is brought up to the level of sugar in human milk. This addition is made before sterilizing. The fat milk has the advantage over the diluted milk of having "a higher percentage of fat," and also it curdles more slowly than diluted milk and the curd forms a more flocculent precipitate.

According to Escherich the following amounts should be used at different ages of infancy, feeding every two to four hours:

Infants under two weeks,	500 c.c. (17½ ℥)	in nine feedings.
" three to four "	750 c.c. (26 ℥)	" eight "
" four to eight "	1,000 c.c. (35 ℥)	" " "
" three to four months,	1,250 c.c. (42 ℥)	" " "
" five to six "	1,500 c.c. (50 ℥)	" seven "

Escherich gives in detail his experience in feeding with fat milk fifty infants in a hospital, including rickety and tuberculous children. He has certainly met with marked success. Some cases have been

under observation for six months. His article is published *in extenso* in *Mitteilungen des Vereins der Aerzte in Steiermark*, No. 1, 1895.

Baginsky[1] mentions Gaertner milk as a new form of food introduced. In our country Jacobi[2] states that Gaertner milk is applicable to the majority of infants who require cow's milk appropriately prepared.

During the last summer I proposed to test the efficacy of Gaertner milk. With this view I have subjected the milk to a very rigid test, inasmuch as the time chosen, from June to October, was the heated term, which is the worst for milk digestion, and the hygienic conditions of the infants were those found in the average tenement house, too well known to need description.

The guides for ascertaining the degree of assimilation were the following factors:

1. The child's general condition, as manifested by its appearance, appetite, and sleep.

2. The presence or absence of gastro-enteric disturbances, such as vomiting, colic, restlessness.

3. The condition of the stools, constipation or diarrhœa, the number of stools in twenty-four hours.

4. The gain in weight; weekly observations.

The nurses or mothers were instructed to note the amount of food taken and the number of stools in twenty-four hours.

We submitted the stools passed in twenty-four hours to Mr. Herman Poole, our chemist, whose chemical report is appended. Thus we have tried to ascertain how much proteids, fat, sugar, and salts were taken, how much absorbed, and how much was voided in the fæces without having taken part in metabolism.

The following cases will serve to illustrate the method pursued in attempting to solve the problem before us and the results obtained as regards the efficacy of the milk:

Case I.—Dorothy Shattuck, a prematurely born child, the labor having occurred in the middle of the eighth month of gestation. For three weeks after birth the child's mother fed her on Borden's "Eagle brand" condensed milk, and then, being discouraged with the results, gave the child to the care of Mrs. Turnure, who brought her to the clinic. For the past week she had fed the child on malted milk and a mixture of milk, cream, and barley water. June 16, 1897, the little patient first came to us at the German Poliklinik. She stated that the child had been getting worse, was extremely irritable, slept badly, had had persistent vomiting and diarrhœa, with six and more watery stools daily. It also had a hacking cough.

Status præsens: An extremely emaciated child, twelve weeks old, weighing 6 lbs. and 12 oz. The head is of normal shape; the face has a peculiar, senile expression; the fontanelles are open, but do not bulge. The scalp is of a reddish color, with here and there a furuncle. The face has a sallow, earthy color; the eyes are kept closed most of the time. The thorax is not deformed; the ribs are not beaded; the thoracic skeleton is sharply outlined; the skin is dry, yellowish. The upper extremities show thick epiphyses; thin, flabby, bluish skin; cold, weak hands; and thin, atrophic long bones. The reflexes are diminished, the grasp is weak. The abdomen is full and pendulous, the abdominal walls are very thin, the intestines are distended with gas. The skin in the groins is flabby; there are no dilated veins and no herniæ. The buttocks and genitals are covered with an erythematous rash (intertrigo); the anal reflex is normal; rectal temperature, 99° F. The lower limbs are similar to the upper—thin bones, thick epiphyses, atrophic muscles, bluish dry skin. The scapulæ project behind; the spine is not deformed; the whole appearance is one of extreme atrophy. The tongue has a white coating; gums normal; fœtor ex ore. There are swollen glands in the inguinal region and furuncles on the thighs. The child drinks water with avidity; a peculiar, lactic-acid smell is exhaled from the body.

Diagnosis: Athrepsia, catarrhus gastro-entericus, rachitis.

Treatment: (*a*) Hygienic: Daily baths; cleanliness in the mouth, clothing, bottles, nipples.

(*b*) Dietetic: The sole diet, Gaertner's mother milk. Three cans (one-third litre in each) in twenty-four hours; beginning with a few ounces at a time, and increasing the dose gradually until eight ounces are given at one meal, of which there should be six in twenty-four hours, *i.e.*, every three hours in the daytime and at longer intervals at night.

(*c*) Medicinal: None.

An irrigation with hot water was used to wash out the colon and rectum before the diet was begun.

June 23d, the child took the milk at first reluctantly; the first doses were vomited at once. The nurse persisted, however, and her efforts were rewarded, for in a few hours the baby began to take the milk in larger quantities and to retain it well. The vomiting and diarrhœa stopped—three stools daily. The child was quiet, and slept twelve to sixteen hours out of twenty-four. Looked cleaner and brighter.

June 26th, the general condition is the same; bowels regular, tongue clean, complexion more natural.

On July 14th the weight was 8 lbs. and 3 oz., a gain of 1 lb. and 10 oz. in two weeks; 26 oz. in fifteen days, equals 1⅔ oz. daily gain. The milk was continued in the same quantities; a fresh supply was furnished at the clinic on every visit. The child was seen two or three times every week.

July 29th, weight, 8 lbs. and 10 oz. Gained 7 oz. in fifteen days, or ½ oz. daily out of the 48 oz. of milk consumed.

August 4th, had an attack of vomiting and diarrhœa, which was relieved by one dose of castor oil. There are three or four stools daily.

August 7th, milk continued as usual. The child looks bright; face smooth and of a natural color. Sleeps well, appetite good.

August 14th, for the last two days there is vomiting following an attack of cough. Child takes her food well; mucous râles on both sides of the chest; temperature, 101° F.; diagnosis of bronchitis. A teaspoonful every three hours of mistura glycyrrhizæ composita, to which some belladonna had been added, relieved the cough.

September 4th, the child has a normal temperature, cough is stopped, general condition is good, digestive organs are in good order.

The child was not seen until September 20th. Weight, 10 lbs. and 14 oz. The child is still taking the milk, and appears to enjoy very good health.

Case II.—Abraham Friedman, one year old, was fed at the breast for the first seven weeks of his life. Since then he had been receiving condensed milk. On July 3d was first seen at the German Poliklinik, with the history of diarrhœa, twelve greenish stools a day, vomiting once or twice daily.

On examination, a pale, bloated child; skin flabby, smooth, and dry; fontanelles open, dentition retarded, ribs beaded, abdomen pendulous, limbs weak, and bones very thin. Weight, 17 lbs. 10 oz.

Diagnosis: Gastro-enteritis, rachitis.

Treatment: An irrigation of colon and rectum with a decinormal saline solution; five grains of beta-naphthol bismuth every three hours.

Diet: Gaertner milk, three or four cans daily, at intervals of three hours.

On July 7th the general condition is better, no vomiting, two or three stools a day.

[1] "Lehrbuch der Kinderkrankheiten," fifth edition, pp. 35–30.
[2] "Therapeutics of Infancy and Childhood," p. 508.

July 14th, the condition remains the same.

July 29th, no diarrhœa, no vomiting; has two stools a day.

August 7th, the child's weight is 20 lbs. and 10 oz.

September 3d, the child receives, in addition to the mother milk, soup and rice. The general appearance is better; two stools daily of a brownish-yellow color. The child was discharged cured.

Case III.—Abraham Bassick, seven months old, first seen at the dispensary July 21st. Previous history: Born at term; for the first three days after birth he received the breast, and then he was fed on condensed milk. The child has an erythema intertrigo and lichen tropicus. Now suffers with diarrhœa, vomiting, and colic. Child is considerably emaciated, and weighs 8 lbs. and 14 oz., including his clothes.

Diagnosis: Athrepsia infantum.

Prognosis doubtful.

Treatment same as in Case I. Feeding: Number of cans daily, three; number of meals per day, six; at night, two.

Clinical results: The child increased in weight; the condition of the gastro-intestinal tract seemed to improve while he was taking this form of food; there were no vomiting and diarrhœa for the first three days after the commencement of the feeding. The child was infected with measles on August 9th, and was removed from our observation. The child died of pneumonia, August 16th.

Case IV.—Grace Bliss, two months old, was first seen August 14th. Mother had a number of miscarriages and lost several children; has had several stillborn children, some covered with an eruption. The present child was born at term, weight not known; has been nourished at the breast until to-day. For the past two weeks the child has been restless, cries a good deal; coughs, has coryza; also has eructations and passes a great deal of wind; three or four greenish slimy stools a day.

The examination shows a large, square head, thick epiphyses, distended abdomen, beaded ribs, flabby skin. There are no eruptions, and their existence previously is denied. The temperature is normal; no enlarged glands. Weight to-day, 11 lbs.; the child has been losing weight gradually.

Diagnosis: Athrepsia, rachitis, lues congenitalis.

Treatment: The breast feeding is to be alternated with Gaertner milk, one to one and one-half cans daily.

The child was seen every other day until August 28th. General condition good, takes the milk readily, there is much less colic, the child seems more contented and more quiet; stools are yellowish and appear more normal in consistence.

On September 1st the child's weight was 11 lbs. and 11 oz., a gain of 11 oz. in two weeks. The child has been watched during the month of September, and has received small doses of calomel—one-tenth grain three times a day for its lues—besides a bichloride bath, 1 to 10,000, every third or fourth night.

We consider this case very much improved.

Case V.—Mary Burghardt, a premature child, born at the eighth month of utero-gestation. Mother reports that it weighed about two pounds (*sic*). It was first seen on the 1st of August. During the first week of life the child appeared fairly well, slept quietly, and took the breast without any signs of discomfort. The child is now eleven days old; we are told that it coughs, moans, and cries when touched. There are frequent, soft stools. The child is about one and one-half feet long, and weighs three lbs. The mother states that she has lost several children in their infancy and had several miscarriages.

Examination: The head is of normal shape, with the soft bones and open fontanelles at this age. The face has a senile expression, but the skin is of normal color. There is no eruption; there are no beaded ribs. The upper extremities are very thin, the hands cold, the feet cold. The veins are enlarged; the abdomen is distended, tympanitic on percussion. The mother states that the skin of the lower half of the body came off in large scales a few days after birth. The skin is dry and shrunken. Temperature, 101.6° F.; pulse, 138.

Treatment: Irrigation; calomel, one-tenth grain t.i.d. Gaertner milk, two ounces every three hours.

The diagnosis of the case was congenital syphilis and athrepsia infantum.

The child was reported considerably improved, but it was thought advisable not to increase the quantity of milk until the 28th of August, when the child received one-half ounce more at each feeding. The child was watched during the month of September, and is considerably improved to-day. Weight, 4 lbs. and 9 oz. on September 25th.

Owing to the coolness of the limbs, inunctions of oil were given every day following the bath, and the child's body was wrapped in cotton wool.

Besides the above cases we have had fifteen patients to whom Gaertner milk was given since the beginning of June last. In some cases it was necessary to add sugar to the milk, as many children objected to the taste. In one case (Case III.) no deductions can be made, owing to the child's infection with measles and pneumonia resulting fatally.

Cases I. and V. serve as splendid illustrations for the proper determination of the value of this food, as both were syphilitic and prematurely born children. The other two children (Cases II. and IV.), although much stronger at the commencement of the treatment, improved very rapidly. We sometimes diluted the Gaertner milk with equal parts of barley or rice water, and if this latter mixture was not retained, then the Gaertner milk was discontinued. In the above cases the milk was borne very well, and is continued up to the present day. Although our experience is not so large as that of Professor Escherich, we feel that we can indorse both his statements and those of Professor Gaertner.

The assimilation of this form of food, judging from the stools, is equal to that of any other modified milk. The German journals assert that rickets and scurvy can be prevented by using this milk. As our observations have not been carried on long enough, we cannot yet corroborate this.

As we frequently notice that some children show a distinct idiosyncrasy when given milk, so it was in one case in which neither cow's milk, nor modified milk, nor breast milk, nor Gaertner milk was tolerated. That child fared best on malted milk, properly diluted.

Conclusions.—The small amount of proteid matter contained in the milk appeared to be very easily assimilated in the cases above mentioned. Case I. is a splendid illustration of a tolerance of this form of feeding, when neither cow's milk, condensed milk, nor malted milk was retained. We felt greatly encouraged, especially in the very hot July days, to find this baby gaining in weight, for it must be remembered that this child, in our city with poor hygienic surroundings, gained, from the end of June to the 14th of July, 26 oz. in fifteen days.

Case II., suffering from summer complaint about the same time, early in July, made very rapid progress, and while it could not digest a dilution of one-third milk and two-thirds barley water without passing six or eight stools a day, fared very well on the Gaertner milk.

Case III. was under observation from July 21st

until August 9th, and, although progressing favorably, unfortunately contracted measles and died.

Case IV., an emaciated child, had been receiving breast milk which did not satisfy it. It frequently nursed from thirty to thirty-five minutes at the breast. The child's mother insisted on nursing it, and thus we gave mixed feeding, alternating the breast milk with the Gaertner milk. Thus the child has received from two to three cans of milk per day, without showing any evidences of colic, and without having gastric or enteric disturbances. The treatment has been continued for over two months.

Case V., the prematurely born child with congenital syphilis, was certainly one which was well adapted for the trial of this form of feeding. When she was first seen there were thick, cheesy stools, which, after the gastro-intestinal tract had been cleaned and feeding changed, showed an entire cessation of the colicky symptoms. When commencing this treatment, the child having previously fed on cow's milk, I ordered all milk to be stopped, and fed the child on barley water and rice water for three days, after which I gave Gaertner milk, one ounce every three hours on the first day, two ounces every three hours on the second day, three ounces every three hours on the third day. Considering the syphilitic condition and the fact that it was a premature child, the increase of 3 lbs. and 7 oz. from August 11th until September 25th, during a period of six weeks, speaks for itself.

In conclusion I desire to thank George Saxe (M.S. at the Columbian University), and Dr. McConville, Dr. De Hart, and Dr. Emil Joel for kind and valued assistance.

CHEMICAL REPORT, BY HERMAN POOLE, U.C.S.

The chemical examinations were made with the idea of working out some connection between the substances ingested and those excreted. To this end the milk fed was analyzed and from this the quantity of each constituent fed to the child daily was determined. The fæces were also examined so as to ascertain the quantity of undigested fat and casein voided. The results of both sets of analyses are given below, the fæces examinations being tabulated and plotted for the better elucidation of the facts.

The Milk.—The milk used in feeding the children contained the following: Fat, 3.05 per cent.; casein, 2.09 per cent; milk sugar, 6 per cent. Specific gravity, 1.0275. Reaction, faintly alkaline.

When cold part of the fat separates out, forming a layer on the top of the liquid. On being warmed and thoroughly shaken, this is completely emulsified and distributed through the fluid. Its appearance is that of a good, rich milk, in taste a little sweeter than ordinary cow's milk; and it is more liquid and mobile.

Each can contained ⅓ of a litre or 20.34 cubic inches, and weighing nearly 9½ ounces. Of this there was: Fat, 0.289 oz.; casein, 0.198 oz.; milk sugar, 0.569 oz.; total, 1.056 oz.

Each child consumed from three to four cans of the milk per day and hence used: 0.867 to 1.156 oz. of fat; 0.594 to 0.792 oz. of casein; 1.707 to 2.276 oz. of milk sugar.

The milk was perfectly sterilized, a can remaining open for five days without thickening or showing acidity. The can analyzed had a shot of solder in it, which was perfectly bright, showing no chemical action and consequently no solution of lead.

The Fæces.—The chemical examination of the fæces was made with a view of obtaining, as nearly as possible, the percentage of undigested fat and casein. To this end the nurses were instructed to deliver at the laboratory three times a week the napkins used during the previous twenty-four hours. They were put into cigar boxes and kept in them until examined, which was on the day of receiving them. In some cases they were in very good condition, but many times they were dry and hard, the deposit adhering so firmly to the cloth that it was almost impossible to remove sufficient for analysis and have it free from adhering cotton fibre. This was especially the case when cotton flannel was used, as was frequently done.

In all cases except No. 1 (Shattuck) the weight of the fæces given is below that actually voided; in case No. 2 as much as twenty-five per cent. can be added to the amount given; with Nos. 3 and 4 at least fifty per cent., and on some days the amount obtained for analysis was not one-half of that actually voided.

The amount of moisture was of course much influenced by that of the liquid excretion, which naturally varied considerably. Still, to avoid necessity of laborious analysis, the hypothesis was adopted that the amount of moisture absorbed from the fæces by the cloth was equal to that added by the liquid excretion. In some cases I think this was correct; in others it is doubtful, especially when the fæces as voided were very thin and the napkin had evidently been kept long enough to become dry. This was a matter very hard to regulate, and must be accepted as found.

The physical appearance did not vary very much in individual cases, except in times of intestinal disturbance. After a few days the cloths of Case I. would have the fæces in a single mass, and of such consistence that over ninety per cent. of it could be easily removed. While the child was suffering from an attack of the diarrhœa, as shown by a rise in the curve, of course such a condition could not be expected. There was a decided improvement in the color in each case, it changing from a dead clayey appearance to a more or less decided yellow, with occasionally a greenish tinge. When dry, as was sometimes the case, the color was uniformly brown or dark brown.

In most cases the fæces at first were very thin and spread all over the cloth, but with those continued for a time this character changed to becoming firmer and more collected in one place. Some of the cases were so poorly taken care of that no mention need be made of the condition, it being hardly possible to obtain a sufficient quantity for satisfactory examination.

With one exception the smell was uniformly very faint and not of an offensive character. The exception is the case of the Bassick child, which was fed with egg albumen in addition to the milk. One of the other cases showed a faint skatol odor twice, but in none of the others was it noticed and in this case there was not sufficient skatol to admit of separation. On many days the lactic-acid odor was not perceptible, although litmus paper showed a faint acidity.

The reaction was almost uniformly acid, not strong at any time, and not measurable except in very few instances, and in these only to a very small fraction of a per cent. (0.005) as determined with decinormal ammonia solution. On some days no change in moistened test paper could be observed after fifteen minutes. No decided alkaline reaction was found except once, and this was in a dried sample, the reaction of which may have been influenced by the urine present.

The quantity in the same case did not vary very much. When a very large figure is given there was evidently an accumulation of two days, as was shown by the physical character. As mentioned above, in some cases I was not able to remove more than half of the total, and of course the amounts given do not fairly represent the quantity. This is true with all cases except Case I., which will average within ten per cent. of the total voided. It is impossible to impress the kind of people from whom these were ob-

tained with any idea of care in this regard, and the cloths brought to me show it.

Remarks analogous to those made regarding the amount of excretion apply as well to the water contained. Still a fair average can be found and will probably be near the correct one. In most cases I was obliged to put all together, wet and dry, to have sufficient for analysis, and this at times caused an abnormal number to appear as the water content. This is notably the case with the Bassick child, in which the water content dropped on one day to twenty per cent., the cloths being practically dry. It was also noticed in regard to this one that in this instance the ordinary strong smell was absent.

In each case the quantity of fat and casein decreased after the milk was used, and remained at a lower percentage. This does not apply to the Bassick case, and in fact this case was amenable to no law but that of uniform filth. Whenever a temporary sickness occurred the percentages would rise, and with the Shattuck child this rise also occurred nearly simultaneously with her being taken to Staten Island, where, although she was reported in good health, the percentages kept higher than when she was in the city, and on her return to the city they fell again. Still, in none of these cases of rise in percentage did it reach that point which was attained at the beginning of the experiments. No notice is taken in these results of the quantity of fat which exists in the fæces combined with calcium, iron, alumina, etc., as insoluble soaps. These have undergone some change in the system, and only the undigested or unchanged fats which were soluble in ether were determined.

The methods used for determining the fat and casein were those mentioned in my paper read before the American Chemical Society at Detroit in 1897. The fæces were dried at 90° F., then at 110° C., and the ether extract taken. This ether extract containing also cholesterin with fat was saponified with alcoholic potassa and the cholesterin taken up with ether. The fat-acid soap was then decomposed by hydrochloric acid and the fat determined. The residue from the ether extraction was then treated with water and with alcohol. The residue thus obtained containing the undigested casein and the epithelial cells from the intestinal tract was digested with diluted hydrochloric acid for ten to twelve hours, and this solution used to determine the nitrogen by the Kjeldahl method. Casein was considered as being fifteen per cent. nitrogen.

Of course these methods may be open to objections, but I know of no better ones, and after trying several others decided that they would suit the investigation and its requirements the best, and I actually believe that the true state of affairs has been shown better than it would have been by any of the methods previously used.

The following tables show the results of the examination, giving the date of receiving the fæces, the general appearance, consistence, reaction, quantity in grams that could be removed from the cloth, and the percentages of water, fat, and casein obtained by the methods given above. The percentages of cholesterin are not given, although they were of course obtained. They did not run in a uniform proportion to the fat, being at times very much larger than at others.

Discussion of the Curves.—The curves are made by using the days of the month as abscissas and the percentages as ordinates. The zero point at the intersection of the axes is then the date of the commencement of the experiment on the line of the abscissas and 0 per cent. on the line of the ordinates.

CASE I.—DOROTHY SHATTUCK.

Date—1897.	Appearance.	Consistence, etc.	Reaction.	Quantity, Grams.	Water, Per cent.	Fat, Per cent.	Casein, Per cent.
June 28th	Clayey	Thin	Acid	28	67.7	5.66	1.06
June 30th	Clayey	Soft	Acid	23	75	4.72	1.06
July 3d	Yellowish	Soft	Acid	26	73.3	3.8	1.16
July 6th	Slight yellowish	Soft	Acid	30	76.1	2.25	1.2
July 8th	Yellowish	Lumpy	Faint acid	29	68.8	2.25	1.12
July 10th	Yellow	Lumps	Nearly neutral	10.8	69.9	3.2	1.06
July 12th	Yellow	Lumps	Neutral	35.7	65	3.24	1.08
July 14th	Yellow	Lumps	Neutral	38.6	65	2.99	1.09
July 16th	Yellow	Lump part quite dry	Faint acid	62.5	55	3.49	1.29
July 18th	Yellow	Lumps	Faint acid	42.6	71.5	2.46	1.05
July 20th	Yellow-brown	Lumps	Faint acid	15.8	63.2	2.5	1.12
July 23d	Three yellow, one brown	Three soft, one dry	Very faint acid	51.8	51.2	2.23	0.79
July 30th	Yellowish	Lumpy	Neutral	33	61.2	2.5	1.85

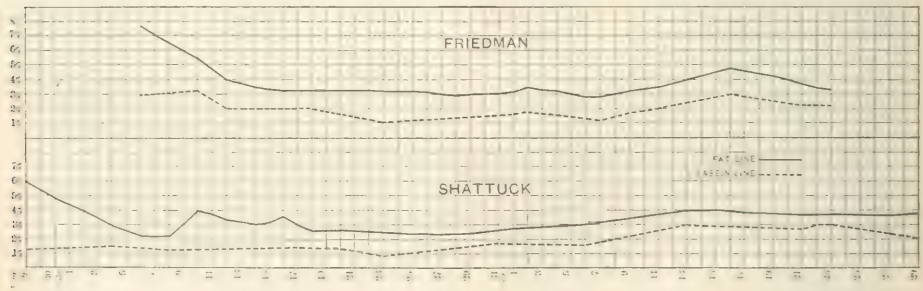
The Shattuck curves: The curve of the casein percentage runs very even until the latter part of July, the time when the child was taken out into the country. While she was there her health was reported good except at the middle of August, when she had an attack of diarrhœa, which lasted some time. This is plainly shown on the curve, both casein and fat lines responding to the conditions. Why the curves rose about July 29th is not explained. The fat curve made a decided downward movement from the beginning, and except for the fluctuations due to intestinal troubles remained low; in all cases it remained lower than it was at its inception. This curve, like that of the casein, tends upward about July 29th, and does not return to its former low figures.

The Friedman curves: With these curves, as with the Shattuck ones, the effect of the feeding is shown by a downward movement. The two lines run closer together than in the Shattuck case, and both respond to the diarrhœa which commenced August 1st and was at its height at about the 17th. The fat curve seemed to respond more quickly to changes in the intestinal tract than did that of the casein, and at times no change in the casein could be determined when a marked one in the fat was evident. At other times, however, from some cause, the casein showed a change not to be noticed in the fat.

The curves of the other cases are not plotted, as they were soon discontinued, and the data obtained were not considered sufficient.



What Constitutes a Maid.—The supreme court of Vermont has decided, in an action of indictment for adultery, that a maiden is "a young unmarried female, not necessarily a virgin."

DIABETES MELLITUS AND ITS TREATMENT: REMARKS BASED ON CLINICAL EXPERIENCE.[1]

BY HENRY S. STARK, A.M., M.D.,

NEW YORK.

In contemplating the character and nature of diabetes mellitus, we are once more confronted with the almost legendary bugbear that, despite all the boasted progress of the medical sciences in our own times, there are still more medical mysteries in heaven and earth than were ever dreamt of by medical philosophers. That this disease is one of the most conspicuous examples in illustration of this text becomes painfully apparent when we recall the slight progress made in our knowledge of it. Pathology has been practically a dead letter, bacteriology has revealed nothing characteristic or constant, while recent elaborate studies of human blood have borne no fruit whatever. Diabetes, therefore, has to this day no definite status as a pathological entity, being known rather as a symptomatic complex or clinical picture, much the same as exophthalmic goitre and certain other medical nondescripts are. It is generally admitted that, in order to establish the identity of a particular disease, it becomes necessary to show that the disease in question is produced by a special cause manifesting itself by distinct pathological conditions; and, further, it must be shown that the particular disease is characterized by distinctive features pertaining to its symptomatology and clinical picture not common to other affections. I scarcely believe that diabetes mellitus comes within the pale of these conditions, and on that account its place in our nosology is still in question. True, there

[1] Read at the meeting of the section on general medicine, New York Academy of Medicine, November 17, 1897.

are extant various theories of its origin and of the nature of the lesion; of these some are radically divergent, while all are based on assumption rather than on the results of post-mortem examinations, and it is just on this account that our knowledge is too presumptive and too ambiguous to be construed in any one constant way. We cannot therefore be expected to accept as incontrovertible truths facts which only hold true at the bedside or on the vivisectionist's table, but which lose their significance in the post-mortem room.

Among the various organs to which was referred the lesion of diabetes mellitus, the most prominent are the liver, the pancreas, and the medulla oblongata. Authorities accordingly speak of hepatic, pancreatic, and cerebral diabetes, respectively. As far as the importance of this classification is concerned for clinical and therapeutical purposes, I have found that I could in most instances discard it without detriment to the health of my patients; in point of fact, I am frank to confess my inability in most instances to differentiate between these varieties. The discrimination from a therapeutical standpoint is scarcely necessary, for viewed in this light the disease has always been a puzzle. The very fact that such divers and ofttimes diverse drugs have been recommended for the cure of it is the very best evidence to prove how inefficient they all are. This postulate holds true for many other affections, while the converse of this proposition, to my mind at least, is just as true—that, whenever any one drug is recommended for the cure of a host of affections, a catholicon as it were, the presumption is strongly in favor of the claim that it is next to useless in most of them.

The first factor in diabetes mellitus is to establish the existence of the disease; this, in view of its unascertained pathology, is not so easy as would appear on first thought, for I know of no disease in which it is so difficult to determine where physiology ceases and where pathology begins. Acute or chronic glycosurias are not, *per se*, sufficient evidence to warrant a diagnosis of diabetes, for we know that both forms of saccharine urine may occur under conditions which are compatible with the enjoyment of good health. We may have a normal or a pathological glycosuria of transient duration; thus also a normal or physiological glycosuria may follow an overindugence in carbohydrates, or may even follow unusual muscular fatigue; in the same way also a temporary pathological glycosuria may be artificially induced by the exhibition of certain drugs, most of which are too familiar to require enumeration; thus also this condition may be produced by lesions of the brain, spinal cord, or nerves. And yet not one of these conditions constitutes diabetes mellitus. Therefore the question arises: When can a person be said to be suffering from diabetes? I believe from my personal experience of numerous cases that two or more pathological phenomena must obtain before a positive conclusion is warranted; namely, chronic glycosuria, polyuria, and polydipsia, and a general deterioration in health depending upon these phenomena. Whenever this triad of symptoms is present, a diagnosis is justifiable.

From a therapeutic standpoint this distinction is of considerable importance, for there comes a time in the course of all chronic glycosurias when we must pass judgment on the case in order to adopt suitable remedial measures. I do not think the criterion suggested by me is too far-fetched, although I can readily understand that some practitioners, particularly life-insurance examiners, would take exception to it. The point, however, to be emphasized is that neither acute nor chronic glycosuria without a depreciation of the general health ought to be considered diabetes mellitus. The presence of sugar in the urine, just as the presence of albumin, has a certain diagnostic value, whose importance is in direct ratio to the changes in the general state of the patient's health.

While on the question of diagnosis I wish to allude to certain signs and symptoms which are not usually mentioned as such in the more familiar text-books, and whose presence, singly or in combination, ought always to arouse suspicion of this disease. Among these evidences of the affection may be mentioned the following: Periodic attacks of headache in obese subjects over thirty-five years of age; extreme fatigue after a short but violent exertion, and prolonged fatigue of twenty-four to forty-eight hours after a slight exertion, both forms occurring in adults; slowly failing vision in the aged or quickly failing vision in the young; certain signs and symptoms referable to the mouth, such as unusual redness of the buccal mucous membrane combined with acid saliva and decaying teeth. This is a combination we frequently encounter in middle-aged women. Two varieties of symptoms referable to the heart and its functions; one set of cases simulating an attack of angina pectoris, *e.g.*, pain in the left præcordial region, radiating up to the shoulder and down the arm, accompanied by dyspnœa and cardiac oppression; a second set of cases which present the physical signs of cardiac hypertrophy or of arterio-sclerosis. This latter set of cases may be met with not infrequently in obese male subjects, with florid expressions and with otherwise healthy appearances. In reference to these cardiac symptoms, it is necessary to state that I do not claim an etiological or a pathological relationship between diabetes and heart disease, nor do I claim that the inroads of the disease exhibit a special predilection for the heart. I am merely reverting to these symptoms and organic changes as frequent coincidences and as sequelæ in the course of diabetes, when perhaps there may be no other palpable deviation from sound health. Still another train of symptoms which has aroused my suspicion of diabetes mellitus was referable to the nervous system. This set was characterized by marked nervousness. The patient, usually an old man, would be possessed of an ungovernable temper, which was aroused under the slightest pretext; generally he would have a morose expression, would be impatient and easily irritated. This set of peculiarities is so familiar, and forms such a classical picture, to German practitioners and even to the laity, that whenever met with in an old man he would be at once labelled by the knowing ones as a person who probably was a victim of diabetes. Other symptoms which should put the clinician on his guard are unusual pallor, premature grayness, slow healing of wounds, and premature sexual weakness.

À propos of the question of diagnosis, I wish here to allude to a possible vagary or anomaly of diabetes, a condition which I might be permitted to style "aglycosuric diabetes" — that is, diabetes mellitus without the presence of glucose in the urine. To illustrate: I have at present under treatment a woman, aged forty-five years, who furnishes all the classical symptoms of diabetes mellitus—namely, marked emaciation, a general nervous and mental depression, polyuria, a ravenous appetite, an uncontrollable pruritus vulvæ; her urine is always of high color and specific gravity, but never shows any trace of glucose. This patient is under my observation for nearly five years, during which time any number of tests and of all kinds were made by myself and others, and yet there never was detected even a trace of sugar in her urine. The clinical history and the character of the urine would enable us to exclude diabetes insipidus. Here, then, is a type of disease which has not yet been recognized in our nosology. The clinical picture conforms most perfectly with diabetes mellitus, and

yet the urine never reacts affirmatively. I have seen a few of such cases, and it is my invariable custom to look upon them as diabetes mellitus and to adopt treatment accordingly.

Before touching upon the treatment of this disease, I wish to make certain observations regarding its prophylaxis. For while we cannot in most instances radically eradicate the disease, we can in a minority of cases prevent its appearance in a number of subjects whose physiological demeanor and whose physical condition plainly indicate that they are candidates for this disease. My experience has taught me one or two points of practical importance which I shall incorporate in these remarks.

First and foremost, when confronted with obese male subjects over forty years of age, physicians should always insist upon and impress their *clientèle* with the importance of suitable muscular exercise. From general inclination such subjects are averse to any such indulgence, for obesity and exercise seem to be diametrically opposed, while obesity and laziness are synonymous. Obesity and diabetes are ofttimes concomitants. If such subjects are of the Hebrew faith this injunction applies with double force, for it is only too well known that this race is peculiarly and unaccountably susceptible to this affection. That the muscular system is largely involved in the glycosuric function is now well established on a physiological basis, for it appears that this system serves as a glycogen reservoir just as the liver does; and that under certain abnormal conditions the quantity stored up is not consumed, but rather finds its way into the circulation and thence into the urine. There is a set of benign cases in which the symptoms have been made to disappear by simply getting the patient to take suitable muscular exercise. This exercise must not be carried to the point of fatigue, but must be taken in moderation and in accordance with fixed regulations.

Another point of practical importance is that the older members of a family in which the diabetic dyscrasia prevails should religiously eschew foodstuffs rich in carbohydrates, while the younger members should indulge in such articles in moderation. Heredity is now known to play an important rôle in the etiology of this trouble. I have seen any number of cases in which this causative factor was pronounced. Thus I have seen three sisters affected, three brothers, father and two sons, grandfather and grandson. Strangely and probably only coincidentally, I have twice observed the disease occurring in husband and wife.

Third precaution—corpulent individuals suffering from gout should positively abstain from sugar and starches, on account of their greater liability to the disease. It would appear from the foregoing prophylactic measures that obesity is one of the principal events in the history of diabetes. That is precisely the experience of most clinicians.

Still another precaution is that all persons who by reason of their occupation or inclination lead an indoor, sedentary life, but whose minds are sedulously occupied, should be warned against their predisposition. Prolonged mental strain or exhausting intellectual occupations are important factors in the etiology of this disease. We constantly meet with cases of glycosuria in which no other causative factor can be discovered.

The medicinal treatment of this disease would furnish a splendid text for a sermon on therapeutics. I believe every drug mentioned in or out of the pharmacopœia has at one time held sway. With the exception of opium and its alkaloids, all have lost their hold on the professional mind. Probably eighty per cent. of physicians are to-day employing morphine, opium, or codeine in the treatment of diabetes. As long as pathology is helpless satisfactorily to account for the disease, so long will its treatment by drugs be empirical and conjectural. I have employed almost every drug advocated, and have finally discarded all save opium and its alkaloids.

At the Eleventh International Medical Congress, held in 1894, at Rome, Monin, of Paris, in an article on the treatment of diabetes, strongly advised the use of permanganate of potassium in the treatment of the rheumatic and hepatic varieties, claiming for this salt that it "invigorates the vital forces, reduces thirst, causes a remarkable diminution of sugar in the urine, but an increase in the number of red globules, and if hepatic congestion be present the liver is reduced in size in twenty days." He prescribed ten drops of a five-per-cent. aqueous solution *ter in die*, and also advised a hot eight-per-cent. infusion of malt at mealtimes. Immediately following the publication of these facts, I also began the use of this salt in the treatment of diabetes. I did not, however, restrict myself to the rheumatic and hepatic varieties, but employed the drug indiscriminately in all types. I have up to date treated about fifty cases of diabetes with the above solution, and with a stronger solution. Many of these cases remained under my personal supervision for several months, and some for several years. In connection with the exhibition of the drug, a moderate antidiabetic diet was insisted upon. I am now in a position to state, as the result of my experience with this drug, that with the exception of a very few cases I do not believe my patients were at all benefited by this mode of treatment, and, further, that I never obtained the favorable results described by Monin. In most cases a mild drug gastritis supervened, rendering its further employment undesirable. In a few cases the drug was discontinued on the appeal of the patient. I have now relegated the salt to an oblivion, as far as the treatment of diabetes is concerned, having satisfied myself of its inefficiency. I believe there is no published record in American medical literature of the use of permanganate of potassium in the treatment of diabetes.

I know of no disease in the treatment of which the personal equation enters so largely as in the disease in question, and just on that account the treatment to be followed in a given case should be determined by individual needs rather than by general considerations. Idiosyncrasy is an important factor. Discretion and good judgment on the physician's part are ofttimes more serviceable than drugs. A blind indiscriminate resort to drugs, in connection with a sudden stoppage of all foods containing sugars and starches, has often resulted in more harm than benefit. It appears to me that it is unwise to cut off suddenly and entirely all such articles of food, just as it is suddenly to stop the use of opium or alcohol in persons who are addicted to their uses. Such drastic measures act as a shock to the system, from which it naturally recoils. If the disease is at all amenable to treatment, it must be attacked by siege rather than by assault. The physician who studies the stereotyped recommendations of the text-books will not meet with half the success that the physician will who studies his patient. While I am ready to admit that I cannot point to any pathological evidence in corroboration of these facts, yet I can submit clinical evidence in substantiation. From a physiological standpoint these facts are almost axiomatic. Physiology teaches that sugar is a constant ingredient of the human economy, and that, deprived of all natural supplies, the system craves for it as it would for salt, but not so markedly. It is reasonable to assume that nature would not have supplied sugar to the body if she did not intend it to fulfil some useful function. The elimination of glucose from the urine

is not in itself an element of danger. Sugar can be demonstrated in the blood and urine of diabetics for days after all carbohydrates have been suspended, showing almost conclusively that even with an exclusively nitrogenous diet there is an invariable supply of sugar in the economy, and that the source of supply is the ingested proteids themselves—that is, the albumin derived from animal food. Since, then, it is known that even albumin may be and is partially converted into sugar, those physicians who advocate total abstinence from carbohydrates might just as consistently advocate a total abstinence from nitrogenous or animal food, on the same principle.

There is a set of cases in which the abrupt suspension of carbohydrates is a positive danger. I refer to those diabetics in whom a rapid emaciation, depending upon a gradual disappearance of the fat of all tissues and organs, is the most pronounced symptom. In consequence of the absorption of the fat of the body, there is a gradual loss of strength and flesh. Now, in view of the physiological fact that the ingested carbohydrates are partially converted in the human economy into fat, just what the system most requires now, the logical sequence would be to make up for this loss by administering foods that contain starches and sugars. This clinical experiment I have tried time and time again, and I verily believe with good results. I therefore allow moderate quantities of carbohydrated foodstuffs in these selected cases, and I have reason to believe that I have tided more than one rapidly emaciating diabetic over a critical period. In these cases also I do not entirely forbid malt or spirituous beverages; on the contrary, I advise and allow their use in moderation. It seems unreasonable to withhold alcoholic stimulants entirely from persons who are accustomed or possibly addicted to their uses, and who are daily losing strength and flesh by reason of such privations. There are certain diabetics, and I have several in mind at this time of writing, who indulged in alcoholic stimulants, contrary to my orders, and who were never the worse for it. The best guide for gauging the quantity of carbohydrated food that is permissible in a given case of diabetes is furnished by a weekly comparison of the body weight of the patient with the quantity of glucose eliminated. Thus if the patient's weight remains stationary or increases, while the quantity of sugar excreted remains fixed or nearly so, the amylaceous food is doing no harm; conversely, if the weight steadily decreases while the glucose increases, the carbohydrates are severely contraindicated. There is a set of cases, usually severe, in which the urine always reacts affirmatively to the yeast test, despite an exclusively nitrogenous diet. Here again the course to be pursued as far as the dietary is concerned should be a compromise one; that is, the three classes of food—carbohydrates, proteids, and fat—should be included in proportions compatible with the conditions. Some dry acid wine, such as Moselle, or white and red Rhine wines, or a light red wine such as claret, is permissible and even indicated. These wines contain a minimum of sugar, while their fermentation has been completed before bottling.

It is always important in the intelligent treatment of this disease to ascertain the quantity of urea eliminated with the urine; for this knowledge furnishes a clew regarding the rapidity and degree in relative terms of tissue destruction or of retrograde metamorphosis. The ratio between the ingested nitrogenous food and urea eliminated, while in no instance a fixed quantity, nevertheless operates in accordance with the fixed laws of metabolism. It is evident that, armed with a knowledge of the rate of urea excreted, the physician is in a position to direct the patient regarding the quantity and the quality of his food. With a knowledge of such a ratio, we have also a guide to maintain a nitrogenous equilibrium, a physiological state which in all diabetics ought to be a matter of solicitude, for by watching this standard we can at times avert the coma or uræmia that may be attributed in certain instances to the enforced conditions of diet; that is, to the unusually large quantities of proteid foods. It is right here that the personal equation in a given case of diabetes enters, and it demonstrates how true the statement is that each case is a problem by itself. It must be apparent that to treat a case of diabetes conscientiously and intelligently we must have a knowledge of the quantity of urea eliminated in the urine. The urine should be tested for urea once or twice every month. There are several methods in vogue. The apparatus and method devised by Doremus are sufficiently correct for all clinical purposes. This method is based upon the chemical fact that hypobromite of sodium decomposes urea into water, nitrogen, and carbonic acid. A graduated scale on the ureometer indicates, approximately only, the quantity of urea in a given quantity of urine. The weekly or fortnightly variations can thus be rapidly estimated.

Considering the valuable data to be derived from a knowledge of the comparative quantities of urea eliminated, it is no exaggeration to claim that its determination is paramount only to a knowledge of the quantities of glucose eliminated. At times it is the only clew which heralds an attack of uræmia or of coma, and oftener it is the only available method to determine whether the economy is surcharged or overburdened with the nitrogenous elements of an exacting, artificial diet. In this connection it is well to remember the fact that diabetic urine contains an excess of urea, a phenomenon by no means strange when we take into account the proteid character of the alimentation; and secondly, the rapid tissue destruction, muscular, adipose, and otherwise, that is an invariable accompaniment of this disease.

From what has been said about urea, it may be reasonably inferred that a like claim will be made regarding the presence of albumin in the urine of diabetics. Albumin is present in about one-third of all cases of diabetes. If present, its quantity should be determined for precisely the same reasons as have been stated above for urea. For the quantitative test I usually employ Eschbach's albuminometer. An albuminuria in a diabetic does not necessarily indicate renal disease, but when it does the question of alimentation will tax the practitioner's ingenuity to the utmost, for it is known that the diet indicated in diabetes is contraindicated in nephritis. Here, then, is a set of conditions or rather complications which will require careful discrimination. In this set of cases the safest plan of operation will be to gauge and compare the quantities of glucose, urea, and albumin, in order to arrive at a working hypothesis, and in this manner to find and to maintain an equilibrium that best suits the exigencies of the case.

There are certain points in the treatment of this disease which have been so well established by time and experience, concerning which there is such widespread unanimity of opinion, that they are equivalent to truisms, and on that account I purposely refrain from mentioning them in this paper.

In a bird's-eye view of this paper, two propositions will stand out from all others as the most important—to wit, that the new and the abnormal ingredients of the urine should be measured, the results being reserved for future reference as an aid to the dietetic treatment; and secondly, that an exclusively nitrogenous diet will often prove to be a menace rather than a benefit to health.

151 East Seventy-Second Street.

PAIN, OPIUM, AND APPENDICITIS.—A PROTEST AND A PLEA.

By ADOLPH KUTT, M.D.,

Even fifteen and twenty years ago one met surgeons who had no great affection for opium in the treatment of peritonitis; but to-day may be one-half or more of the surgeons give it a distressingly cold shoulder. Physicians, on the other hand, are as a rule as fond of this magnificent drug and its derivatives as ever; and I think, speaking as a general practitioner, justly so.

This difference of faith and practice is conditioned by professional habits and experience, besides social circumstances which affect both classes somewhat differently. Pain no doubt has a religious and metaphysical aspect which may be consoling enough to some from a theoretical, or a devotional, or an academic point of view, but when it affects the flesh and bowels of men, women, and children, metaphysics is thrown to the winds and a physician, usually not a surgeon, is called in to put a stop to it as speedily as possible, and by means less excruciating and appalling than the pain itself. To accomplish this end, opium in some form is applied. Afterward the surgeon may be needed. The physician prepares the way for him, and makes his exit easy.

Of late, surgeons have claimed appendicitis to be a surgical disease; but general experience and statistics do not altogether justify the claim. In only a small percentage of cases the surgeon's services are needed, but in every case that comes under medical care the possibility of the surgeon's help is never to be left out of consideration—and only in these senses is appendicitis a surgical disease.

To the writer it seems that surgeons are somewhat paradoxical concerning the administration of opium and its derivatives for the relief of pain. They claim that opium masks the disease—in what way it is not always easy to get definite ideas or indications from them. Physicians know from experience, and many surgeons agree with them, that the severity of the pain is not indicative of the gravity of any particular case of appendicular inflammation. Very painful appendicular trouble may be and is often recovered from within a week's time, and, again, this disease has killed a patient within forty-eight hours without having given rise to much extraordinary pain. Furthermore, the location of the pain is not by any means definitely fixed. All that the symptom pain does for us definitely in the way of diagnosis is to direct our attention to the abdomen for the source of trouble. Pain as such is of only minor importance in arriving at a diagnosis of appendicitis. Such being the case, why not then relieve the patient from pain? Does opium mask the other symptoms and signs of appendicitis or those that indicate its progress for better or worse? A practical experience in hospital and private practice of twenty years' duration urges the writer to answer positively, No! Over and over again he has found in cases of appendicitis and other forms of peritonitis that patients complain of pain on movement, or when the affected regions have been palpated or manipulated, while they were tolerably comfortable under varying doses of opium. Furthermore, opium, far from interfering with the functions of diagnosis in these diseases, also has an indirect curative effect by more or less controlling the local inflammation, by reducing circulatory pressure and diminishing intestinal peristalsis.

To conclude: It has not been the object of this paper to antagonize the surgeon and his due share in the management of appendicitis, but simply to insist on two facts; namely, that pain as such and as a symptom of appendicitis is of but subordinate importance as a factor in diagnosis, but often of pressing and paramount importance respecting therapeutical indications which are best carried out by the judicious administration of opium or its derivatives, oftentimes in large and generous doses. Opium can do no harm to the patient suffering from pain in the course of appendicitis, unless the calm and comfort which it brings benumbs the diagnostic capabilities of the managing doctor. The man who cannot diagnosticate a case of appendicitis and differentiate it from other acute intra-abdominal affections of a suppurative and non-suppurative character which are initiated with and accompanied by pain as a matter of course, ought not to treat any case of abdominal pain unassisted. An incompetent diagnostician will make havoc with even a consulting surgeon, as well with opium as with any other remedy. Thus when opium does harm to a patient suffering from appendicitis, the harm should be attributed to a bad diagnosis, and not to the opium; and, finally, it should not be overlooked that pain as such does not settle the question for operation or diagnosis, and that opium is the only remedy that can kill a killing pain.

406 West Thirty-[illegible] Street.

ELECTRIC TREATMENT IN GOUT AND THE URIC-ACID DIATHESIS.[1]

By ROBERT NEWMAN, M.D.,

From careful observation and experience the author asserts that gout and kindred diseases can always be checked, relapses prevented, and in many cases cured, by the judicious application of electricity, particularly with the static current.

To this association three papers have been contributed, bearing on the subject under consideration. The first was read in 1891, at the first annual meeting, by Dr. W. F. Robinson, on "Electricity in the Treatment of Rheumatism." He recommended the galvanic current in affections of one or two joints, and static electricity if the rheumatism is generally diffused in the body, in which case he gives the static sparks. Applications may be made on alternate days, lasting ten minutes.

At the same meeting Dr. Margaret A. Cleaves read a paper on "The Uses of the Galvanic Current in Articular Inflammatory Exudations." The treatment was by the galvanic current, constant or interrupted. In one case after thirteen *séances* it was followed by faradization. The point taken is the use of electricity during an acute stage instead of waiting for the chronic state. The argument is that electricity can be used in an acute stage, that there is no danger of developing more acute inflammation. By waiting for the advanced stage the case is made more difficult to handle, thickenings of the articular tissues, contractions of limbs, exudations, impairment of movement, even ankylosis being met with. Such teachings are more modern, very rational, and deserve much consideration in the use of electro-therapeutics.

At the sixth annual meeting at Boston in 1896, Dr. J. Griffith Davis contributed a very practical essay, "Uric Acid—The Rôle of Electricity in Its Treatment." Advanced grave cases with complications were cured with the faradic current, but from later observations the good results of the static sparks were acknowledged. Dr. Rockwell[2] says that the galvanic

[1] Read at the seventh annual meeting of the American Electro-Therapeutic Association, in Harrisburg, September 21, 1897.

[2] Rockwell, E.: "International System of Electro-Therapy," p. 33.

current in the treatment of gout and rheumatism should be selected on theoretical grounds, but from his own experience he is in favor of faradization, and the higher its tension the greater appears to be its analgesic properties. For this reason the static induction current, the tension of which is enormous, is often serviceable.

Cataphoresis can be used to introduce therapeutic substances into the system by electricity, in which case it is difficult to say whether the medicine or the electricity gives a benefit. Edison[1] has made experiments with cataphoresis in gouty concretions as follows: A galvanic current of twenty milliamperes was passed through a jar containing an aqueous five-per-cent. solution of lithium chloride, in which the patient immersed his hand up to the wrist. The other hand was similarly immersed in a solution of common salt. The current was given four hours a day for six consecutive days. The size of one of the joints was diminished and pain relieved.

The writer has tried this treatment but found it too heroic, painful, troublesome, requiring too much time, with results not in proportion to the process. Besides, patients as a rule will not submit to four hours' daily treatment.

As a rule galvanism has been recommended in these diseases by former authors. Professor Senator[2] (Berlin) suggests the descending galvanic current in rheumatism; Remak[3] uses strong galvanism. The papers mentioned are rational; they are written with an honest purpose, with close observation of results, and must be accepted as reliable. There is no contradiction even if different currents of electricity have been used and reported successful. There is only one electricity, which is always mingled with some magnetic power; but there are different currents, instruments, and ways to apply it as an electro-therapeutic measure; which to choose, in the particular case, is the art of the physician. Each author mentioned has good reason for applying the current indicated according to the disease, its stage, symptoms, indications, and complications, and the patient himself. The writer would select the galvanic current in cases as mentioned by Dr. Cleaves and others. The static and faradic currents belong to the same class, only one has a higher tension, and as such should be selected in appropriate cases. The writer is familiar with the wonderful power of faradization in absorption of fluid in anasarca, as Dr. Davis has used it. The reasons for selecting a particular method or current will be given later, after a general consideration about uric acid.

Uric Acid.—The literature on uric acid in disease is very abundant, and theories and practice of different writers vary greatly, so that mooted questions arise, and therefore also arise doubts about the present status of many diseases and their treatment. In many ways acknowledged authorities make just opposite statements. The writer knows his shortcomings and his inability to settle such questions, and will not attempt to make positive statements. He also finds that his experiments and the tables thereof are not of any practical value. Hence he offers only observations and references which will show the diversity of views.

Excretion of Uric Acid.—According to Professor Wormley the normal standard of excretion of uric acid is eleven grains daily. In contradiction our modern physiologists state that uric acid seldom, if ever, exists in a free state in normal urine.[4] In normal urine uric acid is combined with sodium, ammonium, potassium, calcium, and magnesium. Therefore the presence of uric acid in the urine manifests a constitutional disease, in which one or several organs are involved, as the liver, assimilation in general, stomach and bowels in particular, the blood, kidneys, ureter, bladder, urethra, etc. As a rule we are told that the retention of uric acid in the system is the cause of disease, while some may state that the uric acid is a consequence of the disease.

The quantity of uric acid in the system cannot be known, because, if the urine contains a large percentage of uric acid, that does not indicate the degree of excess in the system, nor does a clear urine with little or no uric acid prove the absence of uric acid from the system.

The reaction of urine with uric acid is generally considered acid, and a consequence of faulty diet, but it has been also observed that during an abundance of uric-acid excretion the reaction is decidedly alkaline. One observer found a uric-acid diathesis from the drinking of alkaline water.[1]

The cause of uric acid and accompanying gout is generally traced to overfeeding and a consequent plethora, which, however, do not explain the extreme anæmia and weakness observed in many cases.

The presence of uric acid is found in many diseases, of which the following may be mentioned: angina, bronchitis, catarrh, mitral stenosis of the heart, dyspepsia, diseases of the liver and bowels, nephritis, anasarca, headaches and hyperæmia of the brain, lead poisoning, genito-urinary inflammations,[2] neurasthenia,[3] rheumatism, gout, atheroma in arterioles.[4] The following are some of the conclusions of Dr. Pearce's paper:

"That disturbed metabolism is the cause *sui generis* of a number of symptoms in many constitutional diseases.

"That finding, as we have found, such variations in the quantitative findings of uric acid in the same case under apparently similar symptomatology, and with much variation in diet, exercise, etc., we must assume that the cause in many cases is not dietary indiscretions or idiosyncrasy.

"That certain persistent occipital headaches, not relieved by proper glasses or eye treatment, may be due to uric acid deposited in the meninges."

At the last meeting of the American Medical Association in June, 1897, at Philadelphia, in a discussion on gout, Dr. H. C. Wood made some remarks that deserve mention. "He wished it clearly understood, in the first place, that all our scientific knowledge of gout at present amounted to little more than a mass of trundling expectation upon which hereafter was to be built some true knowledge."

The field of uric acid in disease is so wide, and our knowledge about it so indefinite, that it prompts the writer to abandon the larger field and confine himself to gout and its electric treatment, giving good reasons for the selection of the proper current.

Gout may be acquired, and acute or chronic; of the latter, gout as an inherited disease will be particularly considered in this paper.

The Theory of Gout.—There are different theories about the cause and progress of gout and its treatment. The following appear worthy of note:

Gout is a constitutional disease. During painful attacks there is a retention of uric acid and its salts in the system and in the blood. The diathesis being present, faulty digestion causes an attack. The manner of the production of uric acid is not sufficiently

known. The spleen is probably a factor in its causation.[1]

The theory of Garrod[2] is that the kidneys are diseased. An acute relapse of gout is caused by the irritation in the tissues pregnant with retained uric acid. Prognosis in chronic gout is that generally it ends with death, either after long sufferings through complications or suddenly, as in apoplexy or angina pectoris.

Professor Senator says that treatment effects amelioration and cessation of attacks, but no permanent cure; relapses appear at *locus minoris resistentiæ*.

Treatment consists in medicines, diet, exercise, mineral water, and electricity.

1. Medicines have been recommended in great variety and combinations. Some benefit typical cases and may not help others. Sometimes all are unsatisfactory, and one remedy which always has cured one patient may suddenly prove useless for the same individual. Ebstein says alkaline remedies are to be used, not abused. In some cases, however, alkalines aggravate and acids may benefit. Therapeutics of all kinds and forms have been used, but to enumerate them here would be useless.

2. A specific diet ought to be good, but the statements of authorities are very contradictory. Some order a vegetable diet or milk, and no meat; others say meat only. Dr. Senator recommends a mixed diet with avoidance of fat. One patient did not improve on vegetables; was told to eat less of vegetables, more of meat, and improved at once. Almost all physicians prohibit coffee, tea, and alcoholic liquors, which appears to be rational, but in practice we find that patients need whiskey as a diuretic, and grow worse and weak if the whiskey is omitted. My friend, Dr. A. T. E——, says he has attacks of gout, and cures himself by drinking champagne, while other patients provoke an attack by drinking champagne. Dr. Armstrong[3] in the *Journal of the American Medical Association*, May 1, 1897, states that he gives only red meat and hot water.

3. Exercise, active or passive, is perhaps one of the best remedial agents, because it regulates the circulation, stirs up the action of the different organs to a normal state, and thereby eliminates the effete material from the body. Bicycle riding is undoubtedly good exercise.

4. Mineral waters, drunk at the spring, have done good for various reasons, of which one is the execution of all strict orders from the physician at the spring. Carlsbad is the principal place where patients are sent. However, many sufferers get well from electric treatment without ever being at Carlsbad. The writer knows also of some cases which were benefited by drinking imported Teplitz water, which is pleasant to the taste and acts on the mucous lining, and particularly on the kidneys, as a valuable diuretic.

Electricity, sometimes in combination with but often without the aid of any other remedy, has positively cured rheumatism and gout. Different instruments and currents may be used with success, as indicated in the papers mentioned before. In some cases it will be well to vary the mode of application. Gout may be acute and acquired, or hereditary. In the first form a positive cure can be promised in almost every case. The chronic form is more difficult to cure, and the treatment must be continued over a longer period and new attacks guarded against by the early application of electricity. If some cases of chronic gout are not cured, at least the single attacks are, and relapses can be prevented by attention and proper treatment in time, when the system manifests any abnormality. This rule has particular reference to the treatment of hereditary gout with the static current, and to give evidence of this is the particular purpose of this paper.

Static Electricity.—First it must be shown what qualities the static current possesses which make it desirable to choose it in these affections, and what effect it may have in mastering and correcting the irregularities in the system.

Static electricity has the same properties which are attributed to general electricity. It has a high-potential, high-frequency current. The physiological effects of high-frequency, high-potential currents are so well described by Dr. W. J. Morton, who is the pioneer in the therapeutic use of static electricity, and his writings have been so often quoted, that the writer can well omit repeating and referring to them.

We use static electricity in different ways—as massage, as an induced current, in which shape it takes the place of faradization, but generally as a spark or breeze in different varieties. As a rule the patient is placed on an insulated platform, with which the positive pole of the machine is connected. The electricity is thereby concentrated in the platform, and the patient becomes the end of the positive electrode, in which the electricity accumulates. The other electrode connected with the negative pole is managed by the operator and brought near the patient's body. Sparks or breezes, as the case may be, are given, or, more correctly, taken from the patient. For any particular reason the poles may be reversed if the operator sees any indication.

The curative power of the static application has been tried fully as follows:

1. Static electricity is generally diffused in the body, and penetrates deeply through tissues and joints.

2. It acts as a general tonic.

3. The breeze allays any pain, in most instances in five minutes. In very painful affections of the joints it needs several applications before the pain and infiltration are removed; but when an attack is in progress, after three applications in a single day freedom of motion and cessation of pain should be expected.

4. Headaches and confusion of the brain and the uneasiness of the mental forces are removed by the breeze.

5. It equalizes the temperature and restores it to a normal degree, no matter if the temperature has fallen or been raised through the disease. (Dr. Cleaves has made valuable observations on this point.)

6. The circulation is equalized; one distressing symptom in gout is the feet being so cold, like ice—a feeling as if they do not belong to one's body, numb, so that locomotion is almost impossible. The sparks will equalize the blood circulation, and thereby remove that distressing symptom.

7. The animal heat is favored, the action of the skin restored, and even diaphoresis evoked.

8. It stimulates the organs to a better secretion. The liver, bowels, kidneys, etc., which were sluggish or were interrupted in their actions, will resume their function.

9. It favors the excretions of effete material, purifying the system of uric acid, etc.

10. It removes nervous debility.

11. There is an absorption of inflammatory products, in joints as well as of fluids, as we find in anasarca.

12. It replaces exercise and acts as passive motion.

These effects are well established, and have been observed by many authors, as well as by the writer on himself and on other patients.

Analysis for Uric Acid (after no treatment and after electric treatment).—The following analyses by Mr.

[1] Ranke, H. "Beobachtungen über Harnsäure." Munchen, 1858.

[2] "The Nature and Treatment of Gout and Rheumatic Gout," by Alfred Baring Garrod, F.R.S., M.D., London, 1859.

[3] "The Value of an Exclusively Meat Diet in Chronic Gout," Journal of the American Medical Association, August 14, 1897.

Murray, a practical chemist, of the urine of a patient having hereditary gout are submitted to show the relative excretion of uric acid at different periods of treatment. One pint of the quantity voided during the last twenty-four hours was submitted for analysis in each instance. The result was as follows:

Specimen I.—No treatment. September 9, 1897, two weeks after a slight gout attack. During these two weeks the patient had not had any treatment. After a hot day forty-six ounces was passed in twenty-four hours, of which one pint was submitted for analysis, with the following result:

Total quantity for twenty-four hours, 1,305 c.c.= 46 oz. Color, pale, cloudy. Odor, urinous. Reaction, strongly alkaline (ammoniacal). Specific gravity, 1.020 at 15° C.

Deposit, quantity, and general appearance: Abundant, light, flocculent. Phosphates present, albumin present. Uric acid, 0.334 gm.=5 gr. for twenty-four hours. Microscopical examination—triple crystals and amorphous phosphates.

Specimen II.—After three days' electric treatment. An attack of gout beginning; liver sluggish; tongue, thick white furred; left foot very œdematous and painful; impossible to wear a boot; general uneasiness. Static sparks were given for three days, every day for ten minutes, which treatment prevented a serious sickness, and cured. Treatment was given on September 12th, 13th, and 14th. No medicine, no particular diet. September 15th, one pint for analysis of fifty-nine ounces of urine passed in twenty-four hours. Report received as follows, No. 143:

"The Merck Analytic Laboratories,
"New York, September 17, 1897.

"Physical and chemical character: Total quantity for twenty-four hours, 1,745 c.c.=59 oz. Color, pale; odor, strong. Reaction, acid. Specific gravity, 1.020 at 15° C.

"Deposit, quantity, and general appearance: Small phosphatic deposits present. Albumin present, after persistent and careful tests. Uric acid, 0.1360 gm.=2.09 gr. for twenty-four hours. Microscopical examinations show nothing particularly pathological."

On comparison of the two specimens we find that after the treatment by the static electricity for only three days and during a gouty attack, the patient was cured, the attack abated, the urine became acid, phosphatic deposits and albumin were less, and the excretion of uric acid was reduced considerably; while the first specimen, taken when the patient was apparently well, without any electrical treatment, showed more pathological changes of a grave character, in which the larger amount of uric acid is the most important point. To recapitulate, the uric acid in the two cases was: without treatment, excretion of uric acid, 0.334 gm. for twenty-four hours; after three days' electric treatment, excretion of uric acid, 0.1360 gm. for twenty-four hours.

Hereditary Gout.—While it is admitted that gout is a diathetic disease, such diathesis may be entirely congenital and inherited, in which case the afflicted are not able to acquire or prevent the disease. The statistics of Scudamore prove the statement, as in his observations of five hundred and twenty-three cases of gout he traced three hundred and nine to inheritance, the disease having existed in one or two of previous generations. Even Garrod states fifty per cent. as hereditary. The writer has authentic assurance of inheritance and will state only one family history, and from his own observation. The disease ran through three generations, in two continents, and the observations begin with the grandmother, who died in 1836 in Germany. She had been married twice, had four daughters, two by each husband. All four daughters married; all had gout and died from complications: one of apoplexy in 1838, one of angina in 1840, and the last had severe attacks and died of anasarca in 1875, at the age of sixty-nine years. Some of the male cousins of the old lady suffered also with gout. The children of the daughters of the third generation all suffered with gout. One widower married again and his second wife had three children, which are well and still alive, while the three children of the first (gouty) wife all died in consequence of complications of gout; the last son in 1888. Two children of the daughter who died in 1875 went to America, had severe attacks of gout, and the daughter, a widow, died with meningitis in 1888, while her brother succumbed to heart failure in 1886, both with complications of gout and during attacks. The children of the other two daughters were reported dead, except two males, who in 1890 led a miserable existence in Germany and had gouty spells with deformities of the joints. The sufferers in this family were mostly females, none of whom have been reported as high livers; none drank liquors or beer; of some the writer knows positively that they never drank, and others may have drunk a glass of wine on particular occasions like birthdays. This history has been mentioned to show (1) that the gout was inherited, that (2) it could not have been caused from faults in diet or drinking liquors, and (3) that it occurred mostly in females, against the reported statistics which show a very small precentage of females having gout.

The clinical history of chronic gout has been often and well described by many authors; hence only some symptoms will be mentioned here, for the purpose of showing the indications for making static applications. After the patient has had experience for years, he may anticipate each new attack and watch for the same. It generally begins with some dyspeptic symptoms: the appetite is failing, the liver is sluggish, the bowels are constipated; gases in the bowels annoy; there are headache, general depression, failing of mental brightness, no inclination to move about, a slight rise of temperature, a beginning of stiffness in the joints, pain and swelling of the metatarso-phalangeal joint of the great toe, insomnia, general restlessness, pruritus, cloudy urine with excess of uric acid. If only some of these symptoms are observed, static electricity is indicated, as sparks; and in most cases this treatment is so successful that amelioration is produced at once, and after several applications the patient is cured of that attack and restored to his usual health. Medicine is not necessary. If the right time has passed over and the symptoms progress with severe pain in one or more joints, with œdema, so that walking is impossible, the static applications must be oftener made, about three times a day to the swollen joints. The breeze may be applied, or an electrode used in massage; breeze to the head is very beneficial and agreeable. If the disease is neglected, the next step in its progress is increased pain, more joints are affected, the veins are enlarged, more uric acid is retained in the system, and nephritic colic ensues. Cystitis or even urethritis and immobility are increased; there are delirium, excruciating pains, etc. These complications may cause death.

If the static electricity is applied at the right time with care and attention, every attack can be allayed or even prevented, so that the patient is kept comfortable and in apparent good health. This electricity will do the work without any other measures, but adjuvants are not contraindicated and may be used. In all cases under his observation the writer has succeeded perfectly, as stated. As an illustration he will report now phases of his own case:

Case of Hereditary Gout.—Medicine failed, static electricity succeeded. R. N—— has inherited gout

from his grandmother. He has had attacks for twenty years, which became in time more severe and frequent. He has had the usual symptoms, excruciating pains, with all the sufferings described in text-books. Often he could not move about at all, or, if a little better, locomoted in agonies on crutches. Some attacks were aggravated with colic, during which kind friends watched for an opportunity to perform laparotomy for suspected appendicitis. Medicines allayed pain sometimes, at others the same remedies as well as different ones failed. The climax came in September, 1892, when it seemed that in addition acute articular rheumatism complicated the case so much that the pain was constant and excruciating in the joints affected, that any motion or a turning in bed was an absolute impossibility. The case was then treated by a physician of the highest standing and reputation, a professor in the largest college of New York, a man of ample means, a gentleman in every sense of the word, whose attention—a work of love—could not be exceeded by any one, and whose kindness never will be forgotten. The treatment consisted in medicine, pushed for many weeks, and gave no relief or benefit. The prognosis was bad, and ended in the forecast that even if the patient recovered from the present condition it would be impossible for him to exist without spending four or six weeks every year in Carlsbad. The patient could not take more medicine, grew very weak, in which state he was seen by several members of this association, who never expected to see him alive again—in fact he was once declared dead. At a critical moment Dr. Nunn and our lamented member, Dr. Hutchinson, suggested whiskey and beef juice to sustain life, which resulted in marked benefit. Improvement followed through time and sustaining measures, but the patient remained in a low state, crippled, and obliged most of the time to move about on crutches. In the beginning of 1893, friends recommended static electricity, and the first applications were given kindly by Dr. Margaret A. Cleaves three times a week, so that in due time the patient could walk well without any support, without pain. In the spring he met in a car his former medical attendant, who was surprised to see him looking so well, and would not believe that static electricity, without any medicine, had made the improvement. The static applications have been continued at home, whenever required. Sometimes on purpose treatment was delayed until a new attack had been so far advanced that the joint of the great toe was swollen, and the pain increased to such a degree that when he arose in the morning it was impossible for him to use the limb for walking, and locomotion had to be made with a crutch downstairs to the office, where static electricity was applied. The first *séance* ameliorated the bad symptoms, the second application made the state comfortable, and the third—all in the same day—cured the attack. No extra diet was enforced (whiskey moderately used acted as a diuretic and benefited much). Occasionally alkalies were added, which never benefited and sometimes even increased the excretion of uric acid and the general irritability. Through the static-electricity treatment the patient has been kept well, so as to enjoy life without any serious sickness for nearly five years. The hereditary gout is not eradicated, but all acute attacks have been warded off by the timely use of the static machine. The treatment consisted in sparks and breezes as indicated.

Conclusions.—1. There is a variety of causes and symptoms of gout.

2. The diet and treatment, etc., cannot be stated as a routine for all cases alike.

3. It is wrong to treat the disease; the patient must be treated as an individual, according to indications.

4. There are some points in gout and the uric-acid diathesis which are not understood at present.

5. Hereditary gout exists, and will manifest itself in individuals without their own fault.

6. Hereditary gout as a diathesis cannot be eradicated by any treatment, nor is it the consequence of overfeeding or the use of fermented liquors, for the reason that it has been observed in females who dieted and never drank liquors or beer.

7. Static electricity is the best treatment in hereditary gout, and will prevent attacks, if used judiciously at the right time, and thereby keep the patient comfortable and apparently well.

8. Static electricity and other electric currents will cure many of the other varieties of rheumatism and gout.

[illegible]

Progress of Medical Science.

Streptococci of Erysipelas.—At the last meeting of the Société de Biologie, Dr. Lemoine reported that he had isolated from four cases of erysipelas four streptococci, all of which proved inoffensive to rabbits vaccinated with Marmorek serum, although they were rapidly fatal to others. The streptococcus of erysipelas is therefore not always specifically different from that of Marmorek.—*Le Bul. Méd.*, October 31st.

Blastomyces in Epithelioma.—In a study of blastomyces found present in certain epitheliomata, Binaghi (*Zeit. für Hyg. und Infect.*, vol. xxiii., fas. 2) concludes, from the constant presence of parasitic forms of characteristic feature readily distinguished by coloring stains and other chemical substances, that they are to be regarded as specific blastomyces. They are not found in other tissues, either normal or pathological. That they are not accidentally present, but are causative agents of the disease, is to be inferred from their regular disposition and the relation which they bear to the cells of the new growth.

Diagnostic and Therapeutic Utility of Lumbar Puncture.—Monti (*Archiv für Kinderheilkunde*, B. xxiv., H. 1 and 2, p. 94) reports the results noted in twenty-one cases—fifteen of tuberculous basilar meningitis, five of acute epidemic cerebro-spinal meningitis, and one of acute hydrocephalus secondary to cerebro-spinal meningitis—in which lumbar puncture was employed for diagnostic and therapeutic purposes. In the cases of tuberculous meningitis he found puncture to be entirely without diagnostic or therapeutic value. In cases of acute cerebro-spinal meningitis, examination of the fluid obtained by puncture afforded certain reliable indications as to the nature of the disease. In cases, however, in which the acute stage has already been passed and only symptoms of hydrocephalus are present, examination of the cerebro-spinal fluid yields no reliable diagnostic information. Frequent repetition of the puncture in cases of cerebro-spinal meningitis, with evacuation of sufficient quantities of fluid, is not without favorable influence upon recovery, at least in some cases and at an early stage. The evidence, however, is considered not yet conclusive. Stadelmann (*Deutsche medicinische Wochenschrift*, November 18, 1897, p. 745), from observations in a considerable number of cases of tuberculous meningitis, purulent meningitis, cerebral abscess, cerebral tumor, cerebral hemorrhage, embolism, and thrombosis, arrives at the conclusion that lumbar puncture is without therapeutic value. In diagnosis it is of significance only when it yields a positive result, while no conclusion is to be drawn from negative findings. Meningitis is to be diagnosticated only when bacteria are found in the turbid fluid removed by puncture.

New York, December 11, 1897.

TYPHOID FEVER FROM INFECTED MILK.

THE typhoid epidemic at Paterson, N. J., which has been traced to one source of milk supply, affords an exceedingly apt illustration of the real dangers which await innocent and unsuspecting consumers of a widely used and very essential article of food.

While the health officer of Paterson deserves much praise for the prompt and efficient manner in which he traced the source of infection, it is nevertheless a great pity that there was any occasion to demand his skilled services. In the instance in question the same old story of origin is told, in somewhat different form, it is true, but with the same moral at the end. A certain dairyman, acting as a distributing agent for a number of neighboring small dealers, used the water of an infected pond for cleansing his cans. Within twelve feet of the place of washing there was a pipe which carried the drainage from an outhouse infected by typhoid discharges from his sons, who during the preliminary stages of the disease also worked in the dairy. This milk was distributed to such a widely extended district that it is as yet impossible to learn the actual amount of damage that has been done, for, generally speaking, no one can tell whence his milk may come or through how many polluted hands and foul washings it may pass before it reaches his table.

We have still in our mind similar relations of cause and effect in connection with other epidemics of typhoid from milk infection, notably those in Bay Head and Montclair, N. J., in 1894, and in Stamford, Conn., in 1895. In all these the origin of the disease was traced directly to typhoid bacilli conveyed in milk contaminated by dealers having typhoid fever in their families. In the Bay Head epidemic a cowherd, while suffering from walking typhoid, did all the milking for a dairy and infected the milk with his unclean hands. The epidemic in Montclair started from a baker who, while caring for a case of typhoid fever, repeatedly washed his infected hands and allowed the drainage to enter a well, the water of which was used for washing cans in which ice cream was made. In the case of the Stamford epidemic, which was remarkable for the number of persons stricken, the disease was spread by a camp of Italians who infected a well in its immediate vicinity. The water from the latter was used by one milk dealer for washing his cans, and to this particular source were traced fully three hundred and sixty of the reported cases.

These instances of the spread of the fever by milk prove what can be done by competent investigation and systematic examination of the circumstances connected with its spread; but how many similar cases are there in which no such pains are taken and in which the origin of the disease is simply unexplained? Notwithstanding what may be said to the contrary, it is still a generally accepted fact by the profession that typhoid fever never originates *de novo*. It is safe to say that, whenever sufficient pains are taken, the disease can always be traced to a given point of transmitted infection.

This fact, it seems to us, cannot be too forcibly impressed upon the medical man whenever he is called to a new case. If he has not the time or opportunity to trace the particular invasion to its source, his bounden duty is in the direction of making an immediate report of the existence of the fever to the district health authorities. It is quite true that the attending physician can give all the necessary sanitary directions which may guard against the spread of the disease, but in matters concerning the health of a neighborhood exposed to a common contamination he is virtually powerless to act, save by suggestion and advice. If the physician who attended the fever cases at the dairy in question had done his full duty, how much sickness and perhaps death would have been avoided, and how many victims of his culpable neglect might have been spared their present suffering!

DEFECTIVE MEDICAL EDUCATION.

THE epidemic of yellow fever in the South may turn out, after all, to be not altogether an unmixed evil. If by its means more attention should be paid to the study of bacteriology and the etiology of yellow fever itself should be made clear, then it may be said that the good it will have done will outweigh the evil. *The Hospital* of October 9th has an editorial referring to a speech made by the dean of St. George's Hospital at the opening of the winter session of the medical school. In this speech some of the defects in the system of modern medical education are pointed out, and particularly the want of knowledge in Great Britain in regard to tropical diseases. These remarks of Dr. Manson were full of truth, and apply in a lesser degree to the course of study in use in this country. There is no doubt that America is far ahead of England in matters bacteriological, but here, as there, the young medical men who are turned out by the thousands yearly are hardly so thoroughly equipped in practical medical knowledge as they might be. Dr. Manson shows that the curriculum is decided by the examinations, and that a student will not trouble himself concerning any subjects outside the scope of these examinations. Therefore (as doubtless not infrequently happens) when he becomes the proud possessor of a license to practise, he may and probably will be completely ignorant of many diseases. In both countries

a large proportion of medical men will practise in hot climates, and their training is too often not of a nature to fit them for tropical practice. Without a doubt the curriculum in England is not calculated to do so.

According to *The Hospital*, the fact is notorious that men newly qualified, and who should be conversant with the latest improvements and developments in medical science, display a total lack of this knowledge.

SHALL THERE BE A MEDICAL COMMISSIONER OF CHARITIES?

With the approaching change in our municipal government, there comes into existence a new and greatly enlarged department of charities. Henceforth the public charities of the counties of New York, Kings, Richmond, and a part of Queens are to be combined under a single commissioner, having its central office in New York. The occasion seems to us fraught with the deepest interest to the medical profession and to the public. Already the question is being very earnestly and thoughtfully discussed, both in the profession and by workers in charities: Why should there not be henceforth a thoroughly qualified medical commissioner in this governing body? The reasons given in favor of that proposition are, in our opinion, not only unanswerable, but so imperative that the profession ought to bring them to bear upon the appointing power with all the force necessary to their full recognition.

Let us consider the special functions of this department of charities. First, the institutions under its management are hospitals, dispensaries, and asylums. The New York division alone contains four dispensaries, treating over one hundred thousand yearly, and sixteen hospitals, three of which are the largest in the United States. In New York and Kings new hospitals are constantly being both planned and constructed, and the creation of these institutions is to continue from year to year as the wants of the sick poor demand. It follows that the duties of the commission will be chiefly devoted to the work of hospital construction and management, while it may safely be stated that the current every-day duties of the commissioner of the boroughs of Manhattan and the Bronx will be nine-tenths of a purely medical character. Second, an examination of the public charities of New York proves the folly of committing the establishment and management of these institutions entirely to unskilled laymen. For fifty years the department has developed without the slightest regard to scientific methods. With the most beautiful and healthful sites for the development of a great system of public charities, the finest in the world, New York has to-day to show for the millions of money expended on this department a large number of uncouth, ill-placed, and worse-constructed buildings, scattered indiscriminately over the islands of the East River. Third, if we examine these institutions, we find the most crude and inefficient methods of organization and an almost total lack of useful classification of their inmates. Here is a population of seventy-five hundred people, representing every phase of destitution, without the slightest effort being made to study the conditions which brought them to this estate, and without a suggestion or even a thought of applying those remedial measures which would enable them to become self-supporting.

We believe that if a thoroughly competent medical man had been in that commission for the last quarter of a century, we should to-day have a department of public charities unrivalled in this or any other country. Our profession has been far too negligent of its duty to the public interest in allowing this department to develop from year to year under the blighting influences of political partisanship, without even raising its voice in protest. Shall we allow the present opportunity, when the combined charities of the greater city are to come under the control of an entirely new commission, to pass without an effort being made to secure the appointment of at least one medical commissioner? It must be assumed that the incoming political party is desirous of giving to the new city a popular administration of the several departments, and to this end will adopt any reasonable departure from old methods. From every point of view it is apparent that a medical commissioner, especially for the boroughs of Manhattan and the Bronx, whose public charities consist entirely of hospitals and asylums, is not only desirable but absolutely necessary for their efficient management and future proper development.

PUBLIC MONEY FOR PRIVATE CHARITIES.

The annual protest of the large majority of the medical profession of this city against the appropriation of public money for private charities has again been fruitless of the desired results. The Medical League, the Medical Society of the County, and the County Medical Association, through their representatives, made a vigorous fight before the board of estimate and apportionment on Wednesday of this week, and brought to the surface of public discussion many of the vital questions which lie at the root of the present abominable and outrageous methods of dispensing medical charity. In spite of the forcible arguments to the contrary, the board in question voted the sum of $1,312,420 for the very questionable purposes named.

It was very justly claimed by the opposers of the measures that in most of the cases in which claims were made the different institutions were distinctly private enterprises that throve by the annual begging, and gave no adequate returns in really charitable work for the donations received. Some of these, it was urged, either had large annual incomes of their own, were managed wholly in the interests of medical schools, or were carried on for the benefit of close corporations, which seemingly were above all the usual liabilities of strict business accountability. All of which is strictly true, with great shame be it said.

While it is fair to say that there are several really charitable institutions in this city that deserve help from the public, the number is so exceedingly small, as compared to that of the unworthy ones seeking such aid, that one-tenth of the amount of the appropri-

ation would be all that would be actually and legitimately needed. Our good mayor whose charming weakness and genial flexibility are so charitably excused by his friends, voted for the full appropriation. Probably in the excitement of the moment, with his usually irresistible propensity to do something startlingly inconsistent, he forgot the little speech he made at a recent doctors' dinner, in which he declared, as solemnly as was possible for the occasion, that one of the greatest abuses of charity was the appropriation of public money for private purposes.

WANTED, A SANITARY CLEARING-HOUSE.

The usual crop of typhoid cases is attributed by Dr. Edmund Glynn to the holidays. The *British Medical Journal*, referring to this, says that "it is almost a pity that there is not in England some sort of sanitary clearing-house to deal with accidents of this kind. Surely the origin of typhoid contracted at a watering-place ought to be investigated. There is a sort of conspiracy of silence on the part of the sanitary authorities of many watering-places which augurs an evil conscience on their part." While we are far from saying that the city health officer is always right in looking abroad rather than at home for the origin of his typhoid cases, we think it might be not amiss if medical men when asked to recommend a health resort would give the preference to such as are least guilty of this policy of concealment.

News of the Week.

Associated Health Authorities. — At the annual session of the Associated Health Authorities, held at Woodbury, N. J., on November 29th, Dr. Henry Mitchell, New Jersey, secretary of the State board of health, delivered an address on "Boards of Health." Dr. M. P. Ravenel, of the University of Pennsylvania, read a paper on "Tuberculosis and Milk Supply." Dr. T. B. Rodgers read a paper on "The Relation of Contagious Diseases of Animals to the Public Health."

The Plague in India.—The epidemic of the plague shows no sign of abatement at Poonah, Surat, and elsewhere in the Bombay presidency. It has extended to Belgaum and Ahmednagur. At the latter place two-thirds of the inhabitants have already sought safety in flight. The health authorities of Bombay reported that there were twenty-six new cases of the plague, and ten deaths in that city on November 23d.

Sickness and Death in Havana.—It is stated in the latest issue of the public-health reports of the Marine Hospital service that there were six hundred and nine deaths in Havana during the preceding week, equivalent to an annual rate of 158.3 per 1,000. This estimate is only approximate, and it is believed that many deaths, ten per cent. or more, are not reported. According to this report there are about three hundred cases of yellow fever in that city. There were twenty-four deaths from that cause during the week, but two of that number occurring among the civilians, the others in military hospitals. The deaths from enteric, malarial, and the so-called pernicious fevers show a marked increase over the preceding week. The deaths from intestinal diseases are about one-third of the total deaths, but nearly half of those occurring from enteritis are from starvation pure and simple.

Yellow Palms in Typhoid Fever. — A writer in *The Lancet* says that he has remarked in cases of typhoid fever a yellow discoloration of the palms of the hands, which is usually noticeable in the second week and gets darker till the crisis, then gradually disappears as the temperature regains the normal. He asks whether this is a pathognomonic symptom of the disease, or whether it has been merely a chance occurrence in his cases.

A Life of Pasteur.—It is announced that M. Vallery Radot, the son-in-law of M. Pasteur, has nearly finished the biography he has been busy on for some time past. It relates the story of M. Pasteur's life, and includes extracts from his letters.

A Tragedy and a Fortunate Escape.—Last Saturday Thomas Button bought a can of sauerkraut. His wife opened it and put the kraut on the table for dinner, raw. In the can was a piece of meat which was thrown to a small house dog, and he ate it. Mr. Button did not eat of kraut, but his wife did, and shortly after she vomited violently a number of times, and about half an hour after the meat was given to the dog he was found under the bed dead. Mrs. Button thinks a cup of hot coffee was all that saved her life. —*Altoona Journal.*

The American Society of Naturalists. — The American Society of Naturalists and the affiliated societies will meet at Ithaca, N. Y, on December 28th, 29th, and 30th. The other societies meeting with the naturalists are: the Association of American Anatomists, the Association for Botanical Morphology and Physiology, the American Morphological Society, the American Physiological Society, the American Psychological Association, Section H (anthropology) of the American Association for the Advancement of Science.

Medical Periodicals in the United States. — We find, from a newspaper directory recently issued, that the medical profession of that country supports directly or indirectly 275 periodicals, of which 10 are issued weekly, 11 fortnightly, 225 monthly, 6 bi-monthly, and 23 quarterly, with a combined yearly circulation of 16,017,200 copies. Estimating that there are in round numbers 120,000 medical men of all schools north of the Gulf of Mexico, of whom probably not over 80,000 subscribe to a medical journal of any kind, this vast amount of literature seems an enormous burden to carry.—*Health*, November 13, 1897.

A New Pædiatric Journal.—Dr. Jules Comby, of Paris, formerly editor of the *Revue de Médecine Infantile*, which ceased publication about a year ago, is about to establish a new journal, entitled *Archives de Médecine des Enfants*. The new archives will be

published by Drs. Lannelongue, Grancher, Hutiner, Sevestre, Moizard, Brun, and Marfan, under the editorial supervision of Dr. Comby. The journal will appear monthly, beginning with January, 1898.

"The Philadelphia Medical Journal."—The Philadelphia Medical Publishing Company has been incorporated under the laws of Pennsylvania, for the purpose of publishing a weekly medical journal to be known as *The Philadelphia Medical Journal*. The management of the organization has been intrusted to a board of trustees, including representatives of leading medical schools and other public-spirited individuals. Dr. George M. Gould has been chosen editor, and it is expected that the first number of the new publication will appear January 1, 1898.

Physicians in Columbus.—An item is on its rounds through the papers, medical and lay, to the effect that there are thirteen hundred physicians in Columbus, Ohio, or one to every seventy-seven people. The *Columbus Medical Journal* corrects this, saying that there are only three hundred physicians, or one to every four hundred and sixteen people. So there is still room for one more in that pleasant and healthful city.

Obituary Notes.—Dr. Julius A. Skilton died on November 20th, at his home in Brooklyn. He was a surgeon during the civil war, and was later a war correspondent in Mexico during and after Maximilian's defeat. He was for some time consul-general in Mexico City, and finally made his home in Brooklyn. He had not practised medicine for a long time.—Dr. George H. Horn, of Philadelphia, who had been for many years secretary and librarian of the American Philosophical Society, died on November 25th, aged fifty-eight years. He was graduated in medicine from the University of Pennsylvania, and was an honorary member of a number of European scientific societies. He was president of the American Entomological Society, and next to the late Dr. John Labonte he was looked upon as the leading entomologist in America. He was active in the Academy of Natural Sciences, and for some time served as its corresponding secretary. His death was the result of apoplexy, from which he suffered a first attack about a year ago.—Dr. R. N. Short died suddenly at Mechanicsburg, Pa., on December 1st, of heart disease, at the age of sixty-six years.—Dr. E. L. Welling died at Pennington, N. J., on November 29th, of heart disease. He was a graduate of Princeton University and of the medical department of the University of Pennsylvania. He was secretary of the Third Corps Union, which was originally organized for the relief of wounded soldiers, but after the war became entirely social. He was for many years chief surgeon of the New Jersey national guard. In 1896 he became chief surgeon of the Soldiers' National Home, at Hampton, Va., which position he held for about a year, resigning on account of illness.—Dr. Martin Van Winkle, of Little Falls, N. J., died on November 29th, of apoplexy, at the age of seventy-three years.—Dr. Alexander W. Stein died at his home in this city, on December 6th, at the age of fifty-seven. He was born in Hungary, but was brought to this country by his father when four years old. He was a graduate of the New York University Medical School in the class of 1864. He was visiting surgeon to the City Hospital, professor of physiology at the New York College of Dentistry, and a member of the County Medical Society and the Academy of Medicine.—Dr. William N. Gilchrist died at the Windsor Hotel, on December 3d. He was born in Kortright, N. Y., in 1823, and after being graduated from the Vermont Medical College, came to this city in 1847, practising his profession until he retired, about fifteen years ago.—Dr. James Olmstead died at the Hotel Grenoble, in this city, on December 4th, at the age of forty-eight years. He was graduated from the Yale Medical College in 1874. For the past eleven years he filled the post of superintendent of the Connecticut State Hospital for the Insane at Middletown.—Dr. Harrison Willis, a prominent homœopathic physician of Brooklyn, died in that city on December 2d, at the age of sixty-one years. He was a graduate of the Cleveland Homœopathic Medical College in 1864.

The Late Dr. Harrison Allen.—At a meeting of the Philadelphia Neurological Society, held on the 22d of November, the following action was taken:

"*Whereas*, The Philadelphia Neurological Society has heard with great regret of the death of Dr. Harrison Allen, it desires to offer its sympathy to his family and to give expression to its sense of the great loss which has been sustained by science and the medical profession.

"Dr. Allen was deeply interested in neurology, not only as a human and comparative anatomist, but also in various practical directions, as indicated by his valuable contributions to this society and other medical bodies.

"Charles W. Burr, M.D., *President.*
"William G. Spiller, M.D., *Secretary.*"

The Marine Hospital Service.—In the report of Surgeon-General Wyman, of the Marine Hospital service, recently forwarded to the secretary of the treasury, it is stated that, during the fiscal year ending June 30, 1897, there were 54,477 patients treated at the hospitals and dispensaries under charge of the surgeons in the service. This was 673 in excess of the number treated there the previous year; but the total expenditures from the Marine Hospital fund ($538,356) were $21,000 less than those of last year. Naturally a considerable portion of the report is devoted to a consideration of the recent visitation of yellow fever in the South. Up to November 10th the number of cases officially reported was 4,198, with 423 deaths. New Orleans had 1,722 cases and 244 deaths. The surgeon-general says that there is little doubt that the work which was done by the Marine Hospital experts had a marked effect in controlling the spread of the disease and preventing a much more extensive epidemic. How the disease gained admission to this country has not yet been satisfactorily determined. The report gives a description of the national quarantine stations,

and an account of the measures taken to enforce the national regulations at certain points where the precautions taken by the local authorities were inadequate. An effort was made more than a year ago to supplant the national quarantine station on Ship Island by a State quarantine on a neighboring island nearer the shore, but it failed. The report states that attempts have been made by certain parties to excite concern respecting the Ship Island station on account of its alleged proximity to the shore. It has, the report says, been stated that the island is five miles out, whereas it is really twelve. Dr. Wyman repeats his recommendation for the enactment of a national quarantine law, but says that if a new law cannot be passed the strengthening of the present law is a matter of urgency, so that effective measures may be taken to prevent interference with interstate commerce, while also preventing the spread of disease.

Appointments at Manhattan Hospital. — Dr. Charles E. Norris has been promoted from the position of medical interne at the Manhattan State Hospital to that of junior physician. Other changes in the medical staff of this institution include the appointments of Dr. John H. Crosby as junior physician, and of Dr. Erving Halley and Dr. David E. Marshall as medical internes.

An Epidemic of Measles.—The newspapers report that a very extensive epidemic of measles is prevailing in Springfield, Ohio. On the first day of this month one hundred and fifty-one new cases of the disease were reported, and one hundred and thirty-nine cases the following day, making a total of eight hundred cases up to that date. The character of the disease is in general mild and the mortality rate is comparatively low.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending December 4, 1897. November 29th.—Passed Assistant Surgeon S. S. White detached from the *Concord* and ordered to the *Wheeling*.

A Russian Society of Ophthalmology.—The Russian minister of the interior has confirmed the constitution of a new medical society, to be called the St. Petersburg Ophthalmological Society. Dr. Dobrovolski has been elected president of the new society; Dr. Belliaminov, vice-president; and Drs. Gagarin and Sergiev, secretaries.

An Association for the Spread of Skin Diseases is what the French army might be called, if the story told of the wretched condition of the reserves in France is true. It is said that epidemics of skin diseases constantly appear among them, and these are traced to the clothing with which they are supplied, and which is described as frequently filthy and tattered in condition. The reserve force numbers about one hundred thousand men.

Dr. Conrad Diehl, a practising physician of Buffalo, N. Y., was chosen mayor of the city at the recent elections. The *Buffalo Medical Journal* says that his majority was so considerable as to speak strongly of his personal popularity.

The Massachusetts State Hospital for Consumptives, recently built under authorization of an act of legislature passed in 1895, will be ready for the reception of patients early in the year. The buildings consist of an administration building in the centre of a group of low, one-story wooden buildings, arranged upon the arc of a circle, and alternately long and short, in order that free access may be given to the sunlight. The buildings on one side of the group are for men, and the others are for women. Each long building has seven private wards, nine by twelve feet, with open fireplaces; also a general ward, twenty-five by ninety feet, with accommodations for twenty-two patients, each such ward having large brick fireplaces and a ventilating shaft. There is also a "sun room," composed wholly of glass, twelve by twenty-seven feet. This is surrounded by a wide veranda. In the small buildings the general wards have only ten beds each. These wards also have their sun rooms. The hospital is located at Rutland, Worcester County, which lies at an elevation of about twelve hundred feet above the level of the sea. Unfortunately the institution will have accommodations for only about one hundred and fifty patients.

A New Adulteration.—The department of agriculture has discovered that many creameries are using an emulsion of cottonseed oil, which, added to the cream, increases the butter product per gallon of milk, with small chance of detection and a large increase of profit.

A Students' Hospital at Cornell University.—The residence in Ithaca of the late Henry W. Sage has been presented by William H. Sage, of Ithaca, and Dean Sage, of Albany, to Cornell University, for a students' hospital, and, besides equipping it, the donors will endow it with $100,000. The house is located on a plateau, half-way between the city and the campus, standing well above surrounding houses, yet easily accessible by street cars. All necessary additions and alterations will be made. The total amount of the gift, it is believed, will exceed $200,000.

College of Physicians of Philadelphia.—A stated meeting of the College of Physicians of Philadelphia was held on December 1, 1897, the president, Dr. J. M. DaCosta, in the chair. Dr. John B. Deaver read a paper entitled "*x*-Ray Pathology of Fractures about the Elbow," illustrated by stereopticon views. Dr. William S. Forbes showed skiagraphs from a case of anterior dislocation of the head of the radius, and Dr. J. K. Young exhibited a case of fracture of both bones of the forearm near the elbow, with good movement at this joint. Dr. F. Savary Pearce read a paper entitled "A Study of the Blind." The president delivered his annual address; the secretary, the treasurer, chairmen of committees, and clerks of sections made annual reports; and nominations were made for officers and members of elective committees for 1898.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 2, 1897.

EDWARD G. JANEWAY, M.D., PRESIDENT.

Nominations.—*Vice-President*, Drs. O. B. Douglas and W. H. Katzenbach; *Recording Secretary*, Dr. Louis Faugères Bishop; *Corresponding Secretary*, Dr. M. Allen Starr; *Treasurer*, Dr. Henry E. Crampton; *Trustee*, Dr. A. M. Jacobus; *Chairman of Committee on Admissions*, Drs. Henry Ling Taylor and Gorham Bacon; *Committee on Library*, Drs. Joseph Collins and Edward D. Fisher.

Suppurative Otitis Media, its Complications and Treatment.—DR. GORHAM BACON presented a paper on this subject. He said that suppurative otitis media was caused by cold, influenza, exanthematous diseases, diphtheria, typhus and typhoid fever, bronchitis, cerebro-spinal meningitis, pneumonia, tuberculosis, the puerperal state, syphilis, sea bathing, injuries to the drumhead, and the snuffing up of solutions for nasal catarrh. Dentition played an important rôle in its development, as did also adenoid growths and enlarged tonsils. Scarlet fever, diphtheria, measles, and influenza were responsible for most of the cases, so that it was of the greatest importance that the ear should be carefully examined, and, if need be, treated in connection with these disorders. In children the temperature was apt to be very high, and the attack might be ushered in by a convulsion or by severe vomiting. When the pain persisted after the ear had begun to discharge, it was probable that the periosteum of the external ear was involved or that the mastoid was implicated. The most frequent seat of perforation was the lower anterior or posterior quadrant. Acute purulent otitis media might terminate in recovery, with or without permanent loss of hearing, or the disease might become chronic.

In the acute inflammatory stage Dr. Bacon said it was important to apply the artificial leech at once, close to the tragus, and endeavor to abort the disease. If the drumhead bulged, a free incision should be made into it. This should be done only under the guidance of the eye and with the aid of good illumination. If the free incision was not made and proper drainage not established, there would be great danger of the otitis media becoming chronic. If the disease became chronic—th t is, in Shrapnell's membrane—the cavity should be enlarged and the endeavor made to wash out the secretion with a syringe. Granulations should be destroyed by the application of chromic acid or by the use of the curette. If this treatment failed, a cure could be effected in many cases by excision of the ossicles and curetting the attic. Some of the results of chronic otitis media were the formation of granulations and polypi, caries of the ossicula and temporal bone, mastoid disease, suppurative meningitis, cerebral abscess, pyæmia, and septicæmia. In cases of acute otitis media, if the temperature remained high after the incision of the drum membrane and the opening of the mastoid cells, one should think of a complicating pneumonia or perhaps of a sinus thrombosis. In cases of acute mastoid disease the operation should not be deferred until redness and œdema of the tissues over the mastoid appeared and the auricle stood out prominently from the head. In making the diagnosis the two mastoid processes should be compared, as in some persons pressure on an uninflamed mastoid process would cause pain. In the first stage of mastoid inflammation, secondary to acute suppurative otitis media, after incision the artificial leech should be applied, and also the Leiter cold coil, but the latter should not be left on for more than forty-eight hours, for if the symptoms had not subsided by that time immediate operation was indicated. The incision should be made close to the auricle, from the tip to the upper border of the pinna. This incision could be enlarged in both directions if complications existed. When pus was found in the antrum and upper part of the mastoid, it should be remembered that the tip might contain pus, and if this was not liberated it might burrow down into the tissues of the neck, and give rise to septicæmia. When caries of the tympanic roof took place, a collection of pus was frequently found in the temporo-sphenoidal lobe.

Symptoms of Cerebral Abscess.—Cerebral abscess almost always occurred in connection with chronic purulent otitis media. The first stage of abscess was usually marked by irritability, pain, nausea, and vomiting, with a diminution or cessation of the discharge. A symptom of importance was a sudden change in the disposition or temperament of the patient. When pus had formed in the brain, there would be usually a distinct lowering of the pulse rate and a subnormal or but slightly elevated temperature. When aphasia developed in such a case, it was an important diagnostic sign of abscess of the temporo-sphenoidal lobe. Inflammation of the optic nerve was also sometimes present. In cerebellar abscess the most characteristic symptoms were severe headache, nausea and vomiting, vertigo, and facial paralysis. The external auditory canal should always be carefully examined in every case of suspected cerebral abscess. When thrombosis of the lateral sinus was present there would be severe headache, high temperature with decided fluctuations, nausea and vomiting, overdistention of the superficial veins in the mastoid region, and swelling of the tissues around the tip of the mastoid would sometimes be observed. If the jugular vein became involved there would be hardness and tenderness along this vein.

Begin Operating at the Antrum.—It seemed to the speaker important that the opening of the antrum should be made the starting-point of the operation. If caries of the tympanic roof was detected, the opening should be enlarged so as to admit of thorough inspection of the dura. Sometimes a thrombosis would be found in a sinus, even though an exploring needle had withdrawn fluid blood. If the symptoms indicated abscess of the cerebellum the sinus should be exposed first. The question of ligating the internal jugular vein in cases of thrombosis here was still a mooted question. Personally he did not think this was necessary. Pressure should be made on the neck from below upward along the course of the internal jugular vein, in order to remove the thrombi in the end of the lateral sinus. If the flow of blood could not be reestablished from the lower end of the sinus, it became necessary to ligate the internal jugular vein, especially if there was tenderness or induration along the vein. He had never seen any bad results from exploring the different parts of the brain, if care was exercised and the operation was done under strict asepsis. Rapidity of operating was of considerable importance. After evacuating the pus from a brain abscess, great care should be exercised in syringing the cavity. Boric acid should be used, and afterward a loose packing of iodoform gauze. This was preferable, in his opinion, to the use of drainage tubes.

DR. M. ALLEN STARR said that most of the cerebral complications were observed in connection with chronic cases of suppurative otitis media. One should be chary, however, about making a diagnosis of brain abscess in these cases on the first appearance of cerebral symptoms; it was better to watch the case for two or three days before deciding, as not infrequently apparently serious cerebral symptoms would gradually disappear as a free discharge from the ear was established.

Diagnosis of Cerebral Abscess.—The diagnosis of cerebral abscess was a most difficult one to make, and one could not rely implicitly on any one of the symptoms, but must decide after a careful study of a number of the symptoms. Although almost all observers agreed that subnormal temperature is the rule in brain abscess, he had seen with Dr. Bacon a case in which the temperature reached to 105° or 106° F., and was so irregular as to suggest pyæmia and thrombosis of the lateral sinus. Again, much stress was laid upon the presence of a cerebellar gait, yet this was often the result of irritation of the auditory nerve or of irritation of the semicircular canals. Optic neuritis was sometimes present, but not often, probably because there was no time for it to develop.

Locating the Abscess; Visual Aphasia.—Above and back of the ear was the region of the brain concerned in the storage of the memories of the sounds of words. If this part of the brain was injured, the person became unable to understand what was said to him. Again, everything that we called to mind by our visual sense employed the function of the occipital lobe of the brain—the visual centres. The connection between the hearing centres in the temporal lobe and the visual centres in the occipital lobe was made by a long tract lying under the cortex of the brain—a distinct association tract. When this tract was destroyed, as it often was, in abscess of the temporal lobe, if one asked such an individual what some object was that was held up before him, he recognized the object but could not call it to mind and name it, because of the destruction of this association tract. Dr. Starr said that this peculiar lack of association was an important symptom to elicit in cases of suspected abscess of the temporal lobe, yet it was not commonly mentioned in text-books.

Dr. R. F. Weir gave reminiscences of the earlier days of his experience in the New York Eye and Ear Infirmary. He had operated upon nine patients in cases of cerebral abscess of otitic origin, five being extradural and four cases of sinus thrombosis. Of the former only two recovered, and of the latter only one recovered. It was worthy of note that all the recoveries occurred in private practice, and this was probably to be explained by the fact that hospital cases usually came under observation too late. One of the earliest and most successful operators in this class of cases was Schede. Personally his enthusiasm regarding the surgery of tumors of the brain and of epilepsy had cooled off to an extraordinary degree, because such operations at best were usually only of very temporary benefit. In former days sinus thrombosis terrified the surgeon; now it was even more satisfactory to treat than the ordinary cerebral abscess, because its symptoms were usually recognized quite promptly and the cases were treated with facility by those who, by observation and some experience, had acquired the necessary boldness. Although sinus hemorrhage was alarming to witness, we had learned that it was more easily controlled than that from any of the large veins.

Cold Applications Dangerously Misleading.—Dr. A. H. Buck said that he could not agree with Dr. Bacon regarding the advisability of using the Leiter cold coil in the treatment of acute otitis media. In this early stage one must choose between hot and cold applications. In his opinion, both of these agents were vasomotor stimulants, and they relieved the pain through this vasomotor action by diminishing the pressure on the sensory nerve fibres of the inflamed part. Heat had no power to benumb sensation, while cold would do so when carried beyond a certain point. This very application of cold, therefore, served to mislead us, for it was largely by the persistence of pain that we were informed of the necessity of going further and operating. It was probably for this very reason that the reader of the paper had advised that the cold should not be applied longer than forty-eight hours. The application of ice appeared to be getting very popular in this country, and for this reason he felt called upon to emphasize the fact that it was a very deceptive agent.

Dr. H. Knapp reported several cases bearing upon the subject under discussion. In one of these a subsequent post-mortem examination afforded proof of the fact that exploratory punctures might be made freely without giving rise to any irritation or bad results. A colored plate was exhibited from another case, in which an abscess almost completely filled the temporosphenoidal lobe, and was surrounded by a small zone of softening and redness, yet all the rest of the brain was healthy. He felt confident that if this abscess had been operated upon a week earlier, the patient would have recovered.

There was a tract a little deeper than the one referred to by Dr. Starr, which had been found to be implicated in only eight or ten cases of brain abscess. Dr. Weir had stated that acute ear disease only exceptionally gave rise to cerebral abscess, yet according to recent statistics nine per cent. were due to acute otitis media—not only the extradural abscesses, which were very common, but the real cerebral or cerebellar abscesses. These statistics had probably been largely influenced by the prevalence in recent years of epidemic influenza.

Compact Bony Mastoids Specially Troublesome.—Mastoid processes having a structure of compact bone often gave rise to most perplexing symptoms. In these cases there would usually be pain, not only in the mastoid region, but also in the occipital region, and often little or no discharge. Moreover, this pain would be quite variable, ceasing at times altogether. Pain on pressure was of special significance in localizing the inflammatory focus. Even at operation these compact mastoids gave a good deal of trouble, because even if one found the usual "bead of pus" this frequently would not lead the operator to the main collection of pus. In these cases of compact mastoids it would be found very much easier to trephine in the ordinary way, above and behind the ear, into the cranium, and from there explore the middle cranial fossa.

Dr. Robert Abbé said that the discussion had shown most clearly the great risk of allowing a purulent otitis to go on after the onset of serious symptoms. Hemorrhage, sinus pyæmia, and cerebral abscess were the great dangers to be feared. If the mastoid was operated upon quite early, the involvement of the sinus would be exceedingly slight. If, however, the operation was deferred, the signs and symptoms of sinus pyæmia would soon make their appearance—tenderness and induration along the jugular vein. Many of these cases, operated upon at such a late stage, would inevitably terminate fatally, even after the most radical operation. When the cases had gone on to the formation of a cerebral abscess, surgery held out comparatively little prospect of recovery.

Dr. Edward D. Fisher said he thought the question of temperature was important in making the diagnosis in these cases of meningitis and cerebral abscess. The hebetude present in cases of cerebral abscess was a distinctive feature, and optic neuritis was not uncommonly present. In some cases there were but few symptoms during life, and the diagnosis would be made only at the post-mortem examination. The speaker then referred to a case of chronic otitis media which had been operated upon, and a fruitless search made for pus. The patient recovered well from the operation, and afterward had four or five attacks of coma lasting for a few hours, preceded by headache, dizziness, and symptoms pointing toward a cerebellar abscess. There had been no optic neuritis and no elevation of temperature. It was probable that in this

case there was some disease affecting the semicircular canals.

Dr. E. B. Dench referred to the value of local blood letting in the very early stages of an acute catarrhal otitis media. When there was a true cellulitis present, however, he thought time should not be wasted in trying local depletion. The incision into the drum membrane should be early and free, but he did not favor the use of a gauze drain afterward. Of seventy-two patients upon whom he had operated by the removal of carious ossicula and curettage of the tympanic cavity, forty-four were cured; in nineteen the discharge had greatly diminished; the result was unknown in eight; and one had been recently operated upon and was still under treatment. The Stacke operation had been done in twelve instances, eight patients being cured and four improved. Out of one hundred and sixty-four operations he had had but ten fatalities. His experience with epidural abscess consisted of six cases, all of which had terminated in recovery.

Rapid Operating Important.—If an intracranial complication was suspected, time was an important element in the operation; therefore if there was not free drainage from the external auditory meatus he believed in entering the cranial cavity at once through an incision so extensive as to allow exploration of the cerebellar fossa, the middle and posterior cranial fossæ, and the lateral sinus, as well as to enter the antrum, if this was necessary. One should not undertake a mastoid operation without the strictest aseptic precautions. Personally, he never began such an operation without expecting to open the cranial cavity or explore the sinus.

Occasional Absence of Pain.—Dr. J. A. Booth said that he did not think optic neuritis was a frequent symptom of abscess of the brain, except in cases of abscesses of the cerebellum. In two mastoid cases that had come under his observation the pain had been absent, although it was usually a prominent feature. It had been claimed that this exceptional absence of pain was due to the development of a special toxin having anæsthetic properties.

Prevention of these Dangerous Complications.—Dr. E. Gruening said that if the general practitioner would promptly and properly incise the drum membrane there would be no brain abscesses or sinus thromboses to treat; but, in order that general practitioners should be able to do this, they should receive in their student days better instruction regarding the examination and local treatment of the ear.

Dr. Bacon, in closing, said, regarding the use of hot and cold applications, that he had never had any satisfactory results from the former. The reason he had advised stopping the use of the cold coil after forty-eight hours was that this application did certainly mask the symptoms to some extent. It was his practice to remove the coil at the end of forty-eight hours, and watch both the temperature and the pain for a few hours, and examine the ear carefully. In regard to the question of abscesses returning, he said that he felt that there was always this possibility unless every portion of diseased tissue was removed at the operation.

Dr. Bacon then exhibited two brains, one showing a cerebellar abscess and the other a temporo-sphenoidal abscess with carious bone.

National Bureau of Health.—Dr. A. Jacobi, on behalf of the old committee, reported that, as its sphere appeared to be too restricted to meet the present necessities of the country, the committee recommended the appointment of a new one which could more effectually deal with the urgent and complex sanitary problems of the present time.

The old committee was discharged, and, on motion of Dr. Jacobi, the president was requested to appoint a committee of five, of whom he should be one, to consider questions of public health and hygiene, particularly with regard to the better control of infectious diseases, and to prepare a bill to be presented to the United States Congress, either independently or in conjunction with commercial bodies.

SECTION ON GENERAL MEDICINE.

Stated Meeting, November 16, 1897.

Louis Faugères Bishop, M.D., Chairman.

Studies in the Isolation of the Bacillus Typhosus as a Means of the Diagnosis of Typhoid Fever.—Dr. Philip Hanson Hiss, Jr., read a paper with this title. He said that recent experiments on animals whose resistance had been reduced by exposure to noxious gases showed that under such circumstances they could be successfully inoculated with cultures of the typhoid bacillus, and certain phenomena resembling typhoid fever thereby produced. Up to about 1890 the characters of the typhoid-bacillus growth and the other means of differentiating this bacillus from the colon bacilli were few and indefinite, and, as the means of differentiating the typhoid organism from these other colon bacilli became more accurate, the difficulty of isolating the bacillus typhosus from the fæces was greatly increased, and the opinion gained ground that the typhoid bacilli were not found in the stools. In the various bacteriological studies of typhoid fever attempts had been made to separate the specific bacilli from the fæces, urine, and perspiration, and from blood obtained by puncture of the spleen. The last procedure proved too dangerous for general adoption. The examination of the urine gave better results than the blood. Neumann had found the typhoid organism in eleven out of forty-six cases, and another observer had found the bacillus in one case as early as the third day of the disease. There was some reason for believing that the bacilli were found only in those specimens of typhoid urine which contained albumin. The examination of typhoid urine, nevertheless, had been shown to be a practical and important procedure. According to the best modern observers, the typhoid organism could be recognized ordinarily in from forty-eight to seventy-two hours. The colonies were much smaller and of a brighter color than those of the colon bacilli. In April, 1896, Dr. Hiss said, he had begun some investigations on the behavior of various bacteria with certain solid media, and particularly of the bacillus typhosus. Two media were devised—one for the differentiation of the colonies of typhoid bacilli from the colon group by plate cultures, and the other for tube cultures. These media were composed of agar, gelatin, sodium chloride, meat extract, and glucose, in varying proportions, acidulated slightly with hydrochloric acid. On the plate cultures the bacillus typhosus developed into small colonies, with irregular outgrowths and with fringing threads. The colon colonies, on the other hand, were much larger and darker, and as a rule did not form threads. After inoculating these culture media with the specimen of fæces, the cultures were kept in an incubator at a temperature of 37° C. The organisms isolated in this manner had been subjected to the usual tests for recognizing the bacillus typhosus, and definite and positive proof of their identity had been obtained by several observers. Seventy-eight cases had been investigated in this way. Forty-three were reported as clinical typhoid, of which thirty-seven were in the febrile stage and six were convalescent. In a number of instances only one stool had been examined, and the case not further followed, but even then 66.6 per cent. of the cases had given positive results in the febrile stage. But the

most interesting results had been obtained in a series of cases from the New York Hospital. Of these twenty-six cases, twenty-one were in the febrile stage and five were convalescent. Of the febrile cases nineteen were thoroughly investigated, and in seventeen, or 89.5 per cent., the typhoid bacilli were found in great numbers. In the other two the plates were not satisfactory and death occurred early. The bacilli were isolated as early as the sixth day, and as late as the thirtieth day, and in a case of relapse on the forty-seventh day of the disease. The bacilli seemed to be more numerous in the stools after the tenth or twelfth day. In one non-febrile case the bacilli were found on the tenth day of the disease, and after three examinations with the Widal serum test had given a negative result. The fact that the specific bacilli were present in the blood, the spleen, and the urine, and often early in the disease, seemed to indicate that the bacilli occurred more generally throughout the body than had been heretofore supposed, and that they probably did not reappear in the intestinal tract in great numbers until about the time of the breaking down of the intestinal lesions. The bacilli disappeared rapidly from the stools after the fall of the temperature, and when they persisted there seemed to be a special liability to relapse.

Compared with Widal's Test. — Comparing this method of examination with the Widal test, it would be found to possess the advantage over the serum test of positively demonstrating the typhoid-fever infection in a large proportion of cases, whereas the serum reaction might indicate past or present infection, and even then was not always to be relied on.

Dr. William H. Park said that he had had a fair experience with the different methods of isolating the typhoid bacilli, and he was positive that of those hitherto devised this method of Dr. Hiss was by far the best. Elsner's method was often difficult of application, especially in warm weather, and one could not hope to find the colonies under forty-eight hours. By the method described in this paper the bacilli presented as a rule a characteristic appearance, not only as to their general size, but because of the presence of the characteristic threads. Of course, some other bacilli undoubtedly made threads, and it was possible for even an expert to be occasionally deceived. The tube medium seemed to him far ahead of anything of the kind that he had before seen. All of the bacilli so far tested by Dr. Hiss with this medium had been absolutely differentiated, the one from the other, but he had noticed that unless the media were prepared very carefully this differentiation would not occur. As to the practical value to the physician, the speaker said that one could not hope to get positive results in much more than fifty per cent. of the cases, although a larger percentage had been obtained from hospital practice, where more attention was paid to the collection of the stools for examination. Like the sputum examination in phthisis, if the bacilli were found, it was helpful; if not found, the examination was of no value. The same was true of the Widal reaction. It was probable, therefore, that the method would not be used in a routine way, but only in certain doubtful and puzzling cases. It was in this way that the Widal reaction had demonstrated that certain types of fever formerly considered to be typhoid were really not typhoid fever.

The Necessary Apparatus Obtainable at the Health-Board Stations.—Two small bottles had been devised—one for urine, and one for fæces—and these were to be kept at the various board-of-health stations throughout the city for the convenience of physicians. The fæces were collected by means of a glass pipette furnished with the rest of the apparatus.

Typhoid Fever Located in the Kidney.—Dr. W. Gilman Thompson said that in one recent case at the Presbyterian Hospital the value of the test had been demonstrated very conclusively. The patient had had some fever and a tumor of the kidney, which was supposed to be a collection of pus. It was not thought at the time that the case was one of typhoid fever, but the diagnosis had been made by the Hiss method. It was one of those rare cases of typhoid fever located in the kidney. The patient made an excellent recovery, and the tumor disappeared without operation or special treatment.

Dr. T. M. Cheesman said that he felt that the Hiss method was a radical departure from all previous ones, as hitherto the effort had been to inhibit the growth of other micro-organisms. On the other hand, the experiments of Dr. Hiss were made with the idea of obtaining a medium which would enable the typhoid bacillus to grow at its maximum. He had himself examined the typhoid stools in a great many instances in an effort to obtain the typhoid bacillus, and he had been uniformly unsuccessful by the older methods. He had examined the urine in half a dozen instances, and had been successful only once. He had also examined the typhoid spots, and in no case had been able to discover the presence of the specific bacillus. He had examined the blood from finger puncture in twenty-five cases without once finding the bacillus. Elsner's method had given him no better results, and he had found that at the end of forty-eight hours other micro-organisms were very liable to appear and to simulate what Elsner had described as the typhoid colony. He felt, therefore, that Dr. Hiss had done much by his studies to elucidate this difficult problem of isolating the bacillus typhosus, yet there was certainly a great deal more to learn.

Dr. Hiss, in closing the discussion, said that the percentage of positive results in the examination of only one stool was about fifty. In one case at the New York Hospital he had made four examinations of the stools with negative results, yet subsequently the urine had been found to contain the bacilli.

Typhoid Fever in the Aged.—Dr. Morris Manges read a paper on this subject. Many recent text-books, he said, made the statement that typhoid fever is very rare after the fortieth year. Flint, in the last edition of his text-book, had stated that the susceptibility to typhoid infection was not great after the fiftieth year, and still less after sixty years of age, but he had seen several cases occurring about this period of life. Other authors had stated that the apparent immunity from typhoid fever in later life was probably due to the fact that the individuals had been previously rendered immune by an attack of typhoid fever.

Frequency.—Dr. Osler had informed him that out of three hundred and eighty-nine cases at the Johns Hopkins Hospital up to May 15, 1895, five patients, or 1.3 per cent., were between sixty and seventy years of age. Dr. Manges said that in the present year five patients, all over fifty years of age, had come under his own observation. Two of these had been at the Mount Sinai Hospital—one a man of sixty-three, and the other a woman of seventy-two. The third was a man of sixty-two, and the two others were sixty-five years of age. Three of the cases were typical in every way, but two presented the appearance of a pneumonia. These senile cases were often marked by an insidious onset and rapidly increasing depression of the vital forces. Through the kindness of Dr. Tracy, of the board of health, he was able to present the following figures: Of 3,644 persons reported dead of typhoid fever, 610 were over forty-five years of age, 414 between forty-five and sixty-five, and 96 were sixty-five or over—in other words, 14 per cent. were forty-five and over, 11.3 per cent. were between forty-five and sixty-five, and 2.6 per cent. were sixty-five and

over. It should be remembered also that these figures were collated from the deaths from this disease. According to a table prepared for him by Dr. W. H. Park, from cases brought to his notice in connection with the examinations for the Widal reaction, of 124 persons of whom the ages were given, 118 were forty-five years old and under, and 6 were between forty-five and sixty-five.

Symptomatology.—The symptomatology was quite varied in the aged. The onset was often like that of some simple digestive disturbance; epistaxis was infrequent; the fever was not marked, and was very irregular; the roseola was often absent, and if present was exceedingly scanty and atypical; the abdominal symptoms were not pronounced; enlargement of the spleen was slight or wanting; severe intestinal hemorrhages were common. On the other hand, the pulmonary symptoms were always pronounced—congestion, hypostasis, and pneumonia being very common, and often leading to a faulty diagnosis. In a case cited by Dr. Osler the evening temperature at one time was only 97.5° F.; there were hemorrhages scattered under the skin; and the urine contained a moderate quantity of albumin, with granular and hyaline casts. For a few days the temperature was normal or subnormal in the morning, and rose to 100° or 101° F. in the evening. The ecchymosis increased, and then pulmonary symptoms appeared. The case was thought to be one of pneumonia occurring in a debilitated and aged subject, but at the autopsy, made by Dr. Welch, the anatomical diagnosis was typhoid fever, recent croupous pneumonia, and enlargement of the spleen. In this case there were no clinical features in any way characteristic of typhoid fever, and the typhoid state was thought to be secondary to the pneumonia. The extensive cutaneous hemorrhages were such as were frequently seen in the protracted cachexia of old people. In these old people nephritis frequently occurred, and asthenia was always a marked feature, the patient looking more seriously ill than the symptoms and signs would seem to indicate. The duration was very irregular, and convalescence very protracted. Death frequently resulted from syncope.

Author's Cases.—The speaker then briefly referred to the five cases that had come under his observation. The first patient was seventy-two years of age, and complained chiefly of some abdominal distress, with pain over the thorax and on swallowing. There were pneumonia at the right base, slight enlargement of spleen, and some albuminuria. The case resembled a senile pneumonia, and death occurred with pulmonary œdema. Cultures made post mortem from the spleen and from the blood of the inferior vena cava gave pure growths of typhoid bacilli. The second patient, sixty-three years of age, had complained of chills, fever, headache, and sweating for some time prior to admission. There was no eruption or enlargement of the spleen, and the temperature range was anything but characteristic of typhoid fever. The fever assumed after a time a hectic type, which seemed to indicate a septic process. The Widal reaction was negative, but puncture of the spleen after death gave pure cultures of typhoid bacilli. The next patient was sixty-two years of age. When seventeen years old he had had a typical attack of typhoid fever, with a brisk intestinal hemorrhage in the third week. He presented a typical range of temperature in this second illness. In the next patient it had been found difficult to make the diagnosis until the Widal reaction had been obtained on the seventh day. He had some bronchitis and a scanty roseola, associated with slight splenic enlargement. The last case ran the ordinary course of a mild typhoid. The patient stated that he had been ill for over three weeks before admission, with headache, slight cough, and great dryness of the mouth. The liver and spleen were slightly enlarged, and the abdomen was somewhat tympanitic, but there was no eruption. The Widal reaction was negative at the first examination, but was positive two days later, and continued throughout the active stage of the disease.

Treatment.—The indications were to combat the adynamia by tonic treatment, to guard against pulmonary complications, and to watch the right side of the heart. Baths were to be avoided, because of the atheromatous condition of the blood-vessels. Cold enemata or tepid baths might be resorted to.

Watch the Pulmonary Second Sound.—Dr. Andrew H. Smith said that it was only in recent years that the profession had come to realize that typhoid fever could occur late in life. Disease processes were not easily taken on in proportion as the other processes were sluggish, and this probably explained the comparative infrequency of typhoid fever in old age. The condition which existed as a part of senility was not like the diminished resistance observed in younger persons. All the clinical symptoms were as a rule less pronounced than in younger subjects. For example, there was less headache in the typhoid fever of the aged; so with the epistaxis and with the typhoid eruption. The feebleness of the circulation in older persons also gave rise to certain special features. Thus the bronchitis so commonly observed in younger persons would take on the form of broncho-pneumonia in the aged. The feeble action of the heart naturally predisposed to lung disorder. It was important for the physician, therefore, to know the amount of accentuation of the pulmonary second sound, as indicative of the condition of the right heart, and also of the obstruction in the pulmonary circulation. It was always comforting in these cases to find a good pulmonary second sound. In these aged individuals, as a result of the feeble circulation there was a greater tendency to thrombosis and gangrene. Thrombosis of the iliac vein was not uncommon, and a certain proportion of these patients presented gangrene of the lower extremities. He would feel unwilling to subject these old people to a cold bath, although cool enemata and tepid bathing might be very well borne. We should watch particularly for cold extremities and everything indicating impending failure of the circulation. Alcoholic stimulants were indicated in these subjects more than in younger ones. The fact that the liver and spleen were not likely to be so greatly engorged constituted another evidence of the sluggish disease action to which he had already alluded.

Dr. W. Gilman Thompson said that he had looked over the records of typhoid fever cases at the Presbyterian Hospital for the last ten years. Of these four or five hundred patients, only seventeen were over forty-five years of age, only six over fifty, and only two past sixty years of age. These two latter were interesting as demonstrating the possibility of a very typical attack at this advanced age. It had occurred to him that the atypical condition in some of the cases described might possibly be due to a previous attack of enteric fever. The patients to whom he had referred were sixty-seven and sixty-nine years of age respectively, and both had derived the disease from a common source, yet these individuals did not give evidence of extreme senility.

Dr. William H. Thomson said that last October he had observed at the Roosevelt Hospital a case of typhoid fever in a person sixty-two years of age; its course had been perfectly typical, and had been complicated with pneumonia, but the patient had recovered.

Dr. Manges, in closing the discussion, said that the text-books would lead us to suppose that the reaction of these patients to the disease was a sluggish one, but in practice this was not the case; the reaction to the

fever in the typical cases was as obvious as in younger persons. In the atypical cases only was this sluggish reaction noted. The pulmonary disorder would be most likely to attract attention. It was probable that partial immunity was conferred by a previous attack of the disease earlier in life, yet one of his patients had had a prolonged attack of typhoid fever when seventeen years of age, and had lost the immunity conferred by it to such an extent that his attack late in life was a typical one.

Diabetes Mellitus and Its Treatment; Remarks Based on Clinical Experience.—Dr. Henry S. Stark read this paper (see page 844).

Diabetes is Physiology Perverted.—Dr. William H. Thomson said that he looked upon diabetes as a unique disease, because it was the disease which departed from the great principle that "pathology is physiology under difficulties." Diabetes, instead of being "physiology under difficulties," was "physiology itself perverted." It was a disease in which bread, instead of being the staff of life, became itself the direct means of crippling, if not destroying life. The only other disease approaching diabetes in this respect was Graves' disease, because here butcher's meat was as poisonous as saccharine food was to the diabetic. For years the liver had been examined again and again in all cases of diabetes to discover some pathological change, and of late years the pancreas had come forward in this connection, but in a most tantalizing way. There were unquestionably some cases of diabetes in which the destructive change had occurred in the pancreas, yet in others there would be typical and even fatal diabetes without any pathological change being demonstrable in the pancreas. Traumatisms to the spine and cerebral traumatism had been known over and over again to be the beginning of a history of diabetes, and injuries to the abdomen, particularly blows over the liver, had been known to give rise to a typical and even fatal traumatic diabetes. The fact that the carbohydrates were absolutely necessary as fuel for muscular function, Dr. Thomson said, was one of the greatest discoveries of modern physiology. The discovery that there was a difference between the thermogenic functions of muscles and their contractile functions, and that the thermogenic function was the important one, at once showed that it was the oxidation of the carbohydrates, mainly in the muscular system, that kept up the animal heat. The question then arose: May there not be some fault in that system which will account for the symptoms of glycosuria? This singular disease, diabetes, demonstrated to us more conclusively than anything else the imperfections in our knowledge of physiology. The reader of the paper had spoken of glycosuria as though it were not diabetes, and of albuminuria as though it were not Bright's disease. He did not believe in physiological albuminuria or glycosuria, for he had repeatedly noted, in records extending over many years in private practice, that a very slight glycosuria or albuminuria had eventually developed into diabetes and Bright's disease respectively. Glycosuria was the first step toward diabetes, and the degree of severity varied very greatly in different individuals. Our clinical experience taught us that there was a very great difference in the disease depending upon certain factors. Foremost among these he would put age. The younger the person, the worse the prognosis. The only cases in which he was not very much disturbed by finding glycosuria were those of silvery-headed men and women. Those who became diabetic under twenty years of age usually exhibited a very uncontrollable form of the disease. He was firmly of the opinion that it was not the sugar that caused the fatal explosions of diabetes any more than it was the urea in Bright's disease that gave rise to the symptoms of uræmia, but that certain changes occurred in the sugar and allied bodies through the operation of toxins. These toxins were responsible for the development of acetonuria. He was always alarmed when a diabetic patient had a sweetish breath. Another important and closely related clinical fact was the disappearance of the urinary pigments. We had much yet to learn regarding the significance of pale urine in both diabetes and Bright's disease.

Opiates Should be the Last Resort.—He had always maintained that opium should be the very last resort in diabetes instead of being the sheet anchor, as many physicians seemed to believe. The preparations of opium should be used in diabetes, not as curative agents, but rather as a means of smoothing the path to the grave. His treatment of diabetes consisted in the systematic use of intestinal antiseptics, and he was especially strenuous on this point if he feared the supervention of coma. He also believed in the administration of arsenic, cod-liver oil, and iron, and sometimes of phosphorus and alkalies. He maintained that these agents were curative in a certain proportion of cases, particularly in those developing after forty years of age. He was always pleased to learn that a diabetic patient was gouty, because this materially improved the prognosis.

Diet Should Not be too Exclusive.—He was, however, in hearty accord with the reader of the paper regarding the matter of diet. If under a diet containing carbohydrates we found that the patient was not losing weight or developing special diabetic symptoms, no matter if the sugar still persisted, we were justified in keeping up such a diet. He had seen harm done by a too rigid exclusion of carbohydrates from the diet of diabetics. Bread could be taken in the form of very thin slices, so thoroughly browned as to be more than toasted. In his experience potatoes had not been nearly so injurious to diabetics as the cereals. He would much rather have a diabetic take a moderate amount of potato than the special diabetic breads. The question of prognosis should be determined by an experiment to ascertain the extent to which the sugar diminishes under a rigid exclusion of carbohydrates for a period of three days. If the proportion of sugar remained relatively high, the prognosis was certainly far more serious than when the reduction in the quantity was more prompt.

Premonitory Symptoms of Diabetes.—Regarding the early symptoms of diabetes, the speaker said that the great majority of diabetics had sugar in the urine only intermittently at the outset. For this reason the urine should be repeatedly examined if a patient exhibited a decided form of nervous dyspepsia, or a condition of nervousness formerly unknown to the individual, or a tendency to pharyngeal catarrh, or when there was a tendency to cramps in the calves of the legs in the early morning. This last symptom was also common in gout and in chronic endarteritis, but when these conditions could be excluded the symptom was one strongly presumptive of diabetes. Under such circumstances the physician should examine both the morning and evening urine for several days.

Take Warning from a Family History of Gout or Obesity.—Dr. Walter Mendelson said that we had had impressed upon us the fact that diabetes was really the symptom complex arising from several causes. Clinically we could distinguish two varieties—those cases which were very amenable to treatment, and those which progressed more or less rapidly in spite of all treatment. In glycosurics one would usually find a history of obesity or gout in the patient or in other members of the immediate family. This indicated a general state of faulty metabolism. The reader of the paper had very rightly insisted upon the fact that when there was such a family history special care should be taken regarding diet and exercise in

early life. After one had once become quite obese, it was very hard to get rid of the condition. He agreed with Dr. Thomson that a person who exhibited transient glycosuria was always in a condition to develop true diabetes on very slight provocation.

The Body Weight a Guide in the Treatment.—In the treatment we should never aim to cut off the carbohydrates entirely; this might be an ideal treatment, but we should ever keep in mind that the patient is not a chemical laboratory. Instead of estimating the urea, one could be guided in the treatment by weighing the patient. He had observed no strikingly good results from the administration of such drugs as codeine. A sustaining treatment was, however, of importance, and for this reason he was in the habit of prescribing plenty of butter—it was usually more agreeable to the patient than cod-liver oil. Another important point in the management of these cases was to shield the patient from undue mental or physical strain.

Alkalies Most Valuable.—Dr. Max Einhorn was disposed to make a distinction between transient glycosuria and diabetes—in other words, sugar might appear in the urine from slight causes, and yet not give rise to actual disease. For example, the ingestion of an unusual quantity of sugar sometimes causes glycosuria. The severity of the affection could be fairly well gauged by the quantity of sugar excreted in the twenty-four hours. Severe cases might be found even at an advanced age. While there were apparently no specifics for this disease, the prevailing opinion seemed to be in favor of the administration of some preparation of opium in those cases in which sugar was excreted in large quantity and was not controlled by the dietetic treatment. Of all the recognized remedies for diabetes, it seemed to him that the alkalies were probably the most valuable. It was generally admitted that diabetic coma could sometimes be averted by the free use of alkalies. He did not think it was harmful to exclude starchy foods for a short time, but as a rule these foodstuffs should not be entirely prohibited. In his experience the cereals were better than potatoes, because they contain both albuminoid and starchy food; even untoasted bread had been well borne. The main point was not to allow too large a quantity of starchy food at any one time. Vegetables should be given freely, especially lettuce.

Phosphatic Diabetes.—Dr. Andrew H. Smith asked the reader of the paper whether, in those cases in which he had found no sugar and the urine was of high specific gravity, he had thought of the presence of a large quantity of phosphates. There was a variety of diabetes in which there was no sugar, but a large quantity of water was voided and a great excess of phosphates. It was so well known that diabetes frequently had its origin in great mental shock, or in a condition of prolonged mental strain, that we should give this very serious consideration. He had known bank presidents and others in responsible positions to be very markedly diabetic. When there was a well-grounded suspicion of diabetic inheritance, the younger members of the family should not be encouraged to select vocations in which there was likely to be much mental strain.

Locomotive Engineers Peculiarly Liable to Diabetes.—Dr. Smith said that, having learned that locomotive engineers very frequently became diabetic, he had applied to the actuary of the Brotherhood of Locomotive Engineers for statistics, and had learned from this official that this disease was three times more frequent in those following this occupation. This was not surprising when one reflected upon the constant strain under which the work of a locomotive engineer is done. He called to mind the case of a gentleman who became diabetic from the moment of a severe fright occasioned by a runaway accident. The worst thing we could do was to allow a diabetic patient to watch his urine and keep a record of its changes, as this furnished a constant additional shock to the nervous system.

Dr. Stark, in closing the discussion, said that his experience would not warrant his becoming alarmed if the urine contained some sugar after considerable horseback or bicycle riding, and particularly if the next day there was no longer any sugar in the urine. He was not familiar with the subject of phosphatic diabetes referred to by Dr. Smith. In the case that he had cited in the paper the urine had been constantly acid in reaction and free from sugar, nor did it present the characteristics of phosphatic urine.

SECTION ON GENERAL SURGERY.

Monday Evening, November 8, 1897.

W. W. Van Arsdale, M.D., Chairman.

The Lorenz Method in Congenital Dislocations.—Dr. Royal Whitman presented cases of congenital dislocations treated by the Lorenz method. Dr. Whitman said that double congenital dislocations caused great lordosis and wabbling gait. Single congenital dislocation caused lordosis and wabbling gait, but not so great as the double. He presented several illustrations of the condition in this deformity. There had been practically no cures in this country until recent years. Lorenz and others found that the true resistance lay in the anterior fibres of the muscles drawing the head of the femur up and back, and to restore the normal condition it was necessary to overcome this resistance. This was done by extension by means of weights, by extreme abduction and retention. The head of the femur, having been drawn down over the rim of the acetabulum, it was pushed forward to dilate the capsule, fixed, and thus the child was allowed to walk. The first case was that of a child with double congenital dislocation, whose left leg had been replaced with great force, but it had been necessary so to bandage the limb that it was not convenient for the child to walk, and so that portion of the treatment had been omitted. The fifth case was one that was seven years old, and it had required a weight of twenty-five to thirty-five pounds for four weeks before the operation, and when the bone went back it was with a tremendous jar.

Conservative Surgery on the Arm.—Dr. Robert T. Morris presented two cases. Dr. Marablat, of Elizabeth, had operated on the first patient presented. The man had been shot in the elbow by a tow wad discharged from a shotgun at close range. A four-inch incision was made and the damaged structures were removed, embracing the olecranon, a sharp piece of the ulna, and the end of the humerus. The radius remained principally intact. As a result of the operation the arm was shorter than the other, but the man had good use of it and the movements were good. The second case was that of a man whose arm had been run between a wheel and a belt, destroying all the structure about midway between the wrist and the elbow, except a strip of skin and the ulnar artery. The radius and ulna were resected, all the parts sutured, and now the patient had good sensation, could use the arm at ordinary work, could play the violin, and had a good grip in the hand. Dr. Morris spoke of a case in which he grafted three fingers on to a young woman's hand, and the operation was successful. After a short time the patient had good sensation in the grafted fingers, but from sensitiveness, feeling she was an object of curiosity, she asked him to amputate the fingers. He did so, and preserved them, and was

anxious to have an expert dissect them and find where the nerve supply was derived from.

Simple Fracture of the Clavicle Treated by Immediate Suture.—Dr. E. M. Foote presented a case of this nature. The patient was a boy who had his clavicle broken by a piece of machinery with no injury to the soft parts of importance. He was seen two days after the accident. The fracture could not be reduced, and four days after the injury an incision was made: the bones were exposed, but even then they could not be brought into position. The bones were drilled, then brought together, and sutured with kangaroo suture. The periosteum had been torn from a small part of the end of one fragment; this suppurated a little, but recovered, and now the union was strong. Dr. Foote said the operation was not a common one in this country. Spencer reported a few cases, and one case was reported in the *Annals of Surgery* last year, but in Europe a number of cases had been reported. The results were good. Many cases of broken clavicle healed without any treatment, but this method might be employed with good results in cases in which the fracture was irreducible or would not stay reduced, or in which there was interposition of muscle between the fragments, compound fracture, or hæmatoma. It might be employed as a secondary operation in case of pressure upon a nerve. Most operators had used silver wire and some silk, but there was no special reason why an absorbable suture should not be used.

Amputation of the Hip.—Dr. A. M. Phelps presented the case. The patient was a young woman. An aunt had tuberculosis and a paternal uncle died of phthisis. Her illness began three years ago. She had abscess of the left hip, which was enormously large. The veins of the abdomen were enlarged, the lungs showed crepitant râles on the right side, the patient was extremely anæmic, and it seemed that operation in her condition was dangerous. Her liver was enlarged, the urine contained casts and pus, and all indications pointed to amyloid degeneration of the liver and kidneys. On account of the extreme anæmia the blood was forced from the extremities into the trunk, and a bloodless operation was performed, with the exception that the parts were so soft and destroyed by the disease that the obturator artery could be only partially controlled. When the joint was cut down on, it was found that the disease had amputated the head of the femur. The specimen presented showed that the bone was very much destroyed, contained sequestra, and had been amputated by the disease process. The patient was as well after anæsthesia as before, but the ligaments on the extremities could be removed only one at a time or the patient would faint. By putting on flannel bandages and drawing tight and removing from one extremity at a time, the last one was removed at the end of twenty-four hours. After the operation the albumin began to disappear from the urine, the liver to diminish in size, the veins to become less prominent, and at the present time the patient was in good condition. The case was interesting on account of the bloodless operation, the effect of the operation upon the casts and pus in the urine, and the decrease in size of the liver, suggesting the possible effect of operation upon amyloid conditions. Dr. Phelps thought it was important in major operations, when there was danger from loss of blood, to drive the blood into the trunk. He thought the bloodless operation had reduced the mortality from very great to less than twenty per cent.

Operation for Hernia.—Dr. Samuel Lloyd presented a man upon whom he had operated for hernia, and presented photographs taken before the operation. These showed the hernia to be immense. It had been down for twenty years, and was so large that the man could hardly get about. At the operation it became necessary to invert the patient, on account of the pressing out of the colon and coils of small intestine. The man had not suffered any trouble on that side since the operation, but it was interesting to note that six months later there appeared a hernia on the opposite side, which showed that the side on which the operation had been made was quite strong.

Amputation of the Breast.—Dr. Howard Lilienthal presented a case which he thought was interesting from a diagnostic point. The case was that of a woman who had nursed a child, and three months after weaning had a swelling of the breast. He had amputated the breast, because he thought it was all affected. Examination confirmed the diagnosis of tuberculosis. No other organ was affected. The opening was very slow in healing, one place remaining open for fourteen months.

Carcinoma of the Breast.—Dr. Percy R. Bolton showed a woman in whom both breasts were affected by carcinoma. Dr. Tuttle had removed one, leaving the pectoral muscles, and he had later removed the other and had also removed the corresponding pectoral muscle. It was not easy to detect any difference in the strength of the two sides.

Dr. Charles N. Dowd presented a case to show the good result obtained in removing both pectoral muscles in operation for carcinoma of the breast. The statement had been made that the arm was weak after removal of the pectoral muscles, but this was not true in the case presented, for the woman worked right along and suffered no inconvenience—in fact, did not notice any difference in that side.

Dr. Morris, in discussing the case of fracture of the clavicle presented by Dr. Foote, said that by making a very small incision it was possible to drill a hole in one of the bones, and, making a groove in the other, fasten them by means of a trowel pin and get nice union. He wished to congratulate Dr. Lloyd on the good result in such a large hernia.

Dr. J. P. Tuttle said he was much interested in Dr. Lloyd's case, and wished to ask if he found any plates of cartilage in the scrotum. He then presented a specimen of a large cartilaginous plate which he had found in the scrotum in connection with a large hernia. It was situated between the gut and the sac, and the gut had to be dissected off from it.

Dr. A. Ernst Gallant said he would like to mention the case of a woman who had a hernia larger than the one in the case presented. The woman was sixty-two years old, and had been working since the operation, two years ago. He had found her suffering with distention of the bowels after operation, and the nurse using enema and other means to get the bowels to move. The house surgeon was going to operate to relieve the condition, when the speaker relieved the case by means of massage. Beginning at the ileo-cæcal region, he massaged the abdomen in the direction of the colon, and in a short time the bowels were relieved and the patient's suffering ended. In connection with the case presented by Dr. Phelps, he mentioned having seen an operation in the Royal Infirmary, Edinburgh, in which it was not possible to control the hemorrhage except by pressure upon the abdominal aorta, but this procedure worked admirably.

A Report of Thirty-Two Cases of Cancer of the Breast.—Dr. Charles N. Dowd read a paper on this subject. The purposes of the paper were two: 1st, To investigate the benefits to be derived from the operation; and 2d, to illustrate the technique. It could be safely stated that the mortality was less than twenty-five per cent., and the benefits to be derived from the operation were great, as the patient was relieved from the severe suffering and had the hope that there would be no recurrence of the disease. He had operated on twenty-nine patients since 1893. Only

six of these had been operated on three years ago. Of these four were alive and two died of metastasis of the lung. These patients were operated on by Volkmann's method. Of the remaining patients of the series, fifty-two per cent. were now alive, and most of the deaths were from metastasis. The most interesting question was how extensively the tissues should be removed in these operations. Halsted and Willy Meyer had advocated the removal of the pectoral muscles, and since that time this operation had been extensively used. It had been urged against this operation that it was a mutilation of the patient, and that there was a loss of power in the arm. He had operated on twenty-six patients by this method, and all had good use of the arm, although there might be a slight loss in adduction, though imperceptible to the patient. The other muscles acted to make up for the loss of the pectoral muscles. Sometimes there was œdema from removal of the longer veins, but this was temporary. It was said too that there was increase of danger, but this was unimportant. He had but one death, and that was in a woman seventy-three years of age and very weak. Some surgeons advised the removal of the pectoral muscles in the far-advanced cases and leaving them in the more recent ones, but this seemed to him unadvisable, for the greater the hope of saving the case the more thorough the operation should be, if any difference was made. Some argued that the glands from the posterior triangle should be removed. One could not well argue against this, but it was an important question. As to the removal of the skin, the operation should be to remove diseased tissue and not to make flaps for plastic operations. The method of dressing was of great help in healing the wound. The stretching apart could be relieved by putting on a rubber bandage and drawing the parts toward each other from the sides. If there was trouble in covering the wound, skin grafting was the best. It seemed a matter of importance to leave the subscapular nerve. Cases of local or recent recurrence were ones which showed the necessity for the most of the technique. Patients who had suffered very severely were much relieved by the clearing out of the cancer and by proper dressing, and became comfortable, usually getting out of bed about the sixth day and leaving the hospital in twenty-one days.

In discussing Dr. Dowd's paper, Dr. Bolton said he hoped to hear some evidence in favor of the Halsted operation over other operations. He had heard that patients lost the use of the arm to some extent when the pectorals were removed. He thought recurrence came oftener from the skin than from any other portion, which showed that the superficial lymphatics were most involved.

Dr. Meyer said he was much interested in the paper. He had advocated primarily cutting the tendon of the pectoralis major, and then the minor, and turning these muscles down and dissecting. Halsted's method meant cutting the muscles from the sternal end and splitting and working toward the attachment to the humerus. He thought the two methods were quite different. Halsted took three or four hours for an operation. He thought it best to remove both pectoral muscles. He had had nineteen or twenty cases, and had never seen one in which it was necessary to use a saline solution for intravenous injection. The assistant should not draw the muscle hard. In reference to Dr. Bolton's question as to the result upon the strength of the arm, he thought in every instance the result was better when the muscles were removed. Patients were not troubled with œdema and could soon move the arms. He thought the pectorals should be removed, especially as there were sometimes infected glands below the pectoralis minor.

Dr. Lilienthal said he was in favor of this operation, but the removal of the pectoral muscles must be accompanied by some loss of power; nevertheless, the loss was not so great but it was counterbalanced by the increased thoroughness of the removal of tissue that might cause future trouble. He would suggest to Dr. Dowd the use of zinc plaster instead of rubber, as the latter was more likely to cause irritation and produce sores.

Dr. Morris said the coraco-brachialis and deltoid carried on the work when the pectoral muscles were removed. In some very fat patients, when there was a deep hole it could be filled in with clots of blood, but these must be saved in saline solution while the operation was going on. In cases in which there was suffering from œdema, alternate dipping in cold and hot water would give relief. Some of his patients suffered from neuralgia, but authors did not say much about that condition.

Dr. Samuel Lloyd thought there was little doubt that the complete operation was the best. He favored beginning in the axilla, cutting the tendons of the muscles first, and cleaning the axilla without drawing on the muscles. This also avoided working in cancerous tissue toward the lymphatics of the axilla. It seemed important to him not to make tension across the axilla. He preferred to make flaps from contiguous skin.

The chairman called for Dr. H. A. Ochsner, of Chicago, who said he had come for the purpose of being instructed, and he had been. The profession of his city felt jealous of the New Yorkers, because they had such a handsome library, elegant meeting-place, and brilliant organization.

The chairman also called for Dr. W. J. Mays, of Rochester, Minn., who said he did not come to make remarks upon the valuable papers. In the operation leaving the pectorals there seemed to be more pain from contraction than in the Meyer operation. The paper showed that the best result could be expected when the operation was performed in the early stages.

Dr. Dowd said he had not used blood clots in filling in the wounds. As to resulting neuralgia, he had seen a good many cases of it, but they did not last very long—some perhaps for a few months, none ever more than a year.

Bottini's Method for the Galvano-Caustic Radical Treatment of Hypertrophy of the Prostate, with Demonstration of Instruments.—Dr. Willy Meyer read a paper on this subject. He said the surgeon found it difficult to advise the best method of radical operation for hypertrophy of the prostate gland, for there were many operations and the difficulty was in selecting the better one. This was especially so if the patient was over fifty years of age and refused to have the testicles removed or the vasa deferentia resected. Whether prostatectomy should be tried, or an effort made to influence the size by ligating the internal iliac arteries, or to establish suprapubic fistula with permanent drainage of the bladder, was a question. He had seen patients get along very well with a suprapubic fistula, but others suffered a great deal. We were indebted to Dr. A. Freudenberg, of Berlin, for calling attention to Bottini's galvano-caustic radical operation. It was strange that so excellent an operation should be used by only one man for twenty-two years, and that man the author of it, when the operation had been presented to the profession by the author. It was probably due to the fact that the instrument was made in Italy, and Bottini was ever expecting to make improvements. Now the instrument was made by W. A. Hirschmann, of Berlin, and its manufacture could be relied upon. Bottini first operated in 1875, using what is called the "cauterizzator" and incisor, in the shape of a catheter of medium calibre, with short beak, carrying a porcelain disc on a platinum plate about three-fourths of an inch

long. With this plate, made redhot with the electric current, he cauterized the prostate thoroughly at different spots, and if necessary repeatedly. When the eschar was pushed off, improvement began. Sometimes it was thirty days before the patient felt the change. Two years later he published five successful cases. Then he used only the incisor, which removed the mechanical obstruction to the outflow of the urine by slowly burning a groove or grooves through the same and not by superficial destruction. Dr. Meyer presented this instrument to the society. It was made with a male and female arm; the shank contained a platinum knife, about five-eighths of an inch long, which left the groove of the female arm on turning an Archimedean screw at the outer end of the instrument. A scale attached regulated the length of the groove to be cut. There was also a cooling apparatus which prevented injury to the bladder or urethra. The operation should be preceded by cystoscopic examination. This would exclude the possibility of vesical calculi, and then it was possible to diagnose the presence of a median lobe to the prostate. Dr. Meyer said he had done this, as operation afterward confirmed the diagnosis, and he mentioned it because Dr. Fuller maintained in the section on genito-urinary surgery that it was not possible. The technique of Bottini's method was simple. The bladder was emptied and irrigated; the posterior urethra locally anæsthetized with cocaine by injecting one and one-half drachms of a one or two per cent. solution directly into the posterior urethra or into the anterior, and gentle massage applied over the perineum. Five minutes later the operation could be performed. The bladder must be thoroughly emptied before introducing the cautery, for the cautery is then much more effective. It would be found in many cases that the gland surrounded the internal urethral orifice like a collar. Having tested the instrument to see if it is perfect in all respects and the cooling apparatus all right, Bottini burns three grooves—the first toward the symphysis, another just opposite directly back toward the rectum, and one through the lateral lobe that is the larger. Dr. Meyer described the operation in detail. The operation lasts, according to the number and length of the grooves cut, about five minutes. The patient suffers but little inconvenience during or after the operation. It had been performed without cocaine, and the patient said he preferred it to examination with the stone searcher. Soon after the operation the patient generally complains of a burning sensation on passing water. Most of them remain permanently out of bed, the general reaction being almost *nil*. If the bladder has been carefully irrigated there is no rise in temperature. In eighty cases Bottini had not seen a serious hemorrhage, and advises against the permanent catheter. The effect is often immediate. Even patients eighty years old, slaves to the catheter, commence to void the contents spontaneously a short time after operation. Dr. Meyer mentioned some of the theoretical objections to the operation, but experience had proven these unimportant. A careful observer had never seen a recurrence in twenty-two years. The writer gave a short *résumé* of the operations performed by different physicians and their results. He thought the operation should be given a fair trial, and if it should really prove to be of such great value in the greater number of cases of this dreadful disease, it would become a duty to place it first among the radical operations for hypertrophy of the prostate gland.

Dr. Alexander discussed Dr. Meyer's paper at length. He thought there was doubt as to the extensive use of an instrument with which it was necessary to work in the dark. All his remarks were necessarily theoretical, for he had not had any experience with the instrument. He believed that there were many cases in which it was not so much a question of operation as scientific surgical catheterization.

Dr. Meyer said there had been reported only two accidents. These were hemorrhage. With the perfection of the instrument as it was now made there was apparently no danger in the operation.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, November 22, 1897.

Arthur M. Jacobus, M.D., President.

Address of the President-Elect.—Dr. A. M. Jacobus delivered this address, and, in doing so, presented an outline of what should be the work of the society for the new year. He said that he was heartily in favor of the dispensary bill of last year, if slightly changed, and believed that if physicians, like the members of other professions, would get together and stand by one another the result would be sure. But the desired reform could be secured only by legal enactment.

Regulations for Midwives.—As the Society of Medical Jurisprudence at the meeting this month had appointed a committee to investigate this matter, he suggested that the committee on legislation of the County Medical Society should confer with this committee, and report back to the society.

Public Hygiene.—Touching upon other matters relating to public health, the speaker suggested the establishment of water-closets at drug stores or other places, at suitable intervals throughout the city; the advisability of carefully looking into the claim that the asphalt pavements were injurious to health by forcing noxious gases into houses; and the sanitary aspect of the long school hours for young children, with desks not adjustable to the varying heights of the little pupils.

A Fighting Society.—In reviewing some of the past work of the society, the speaker said that certain persons had referred slightingly to the County Medical Society, dubbing it "a fighting society." As the society had fought persistently for the honor of the medical profession and for the public good, by endeavoring to suppress quackery, this assertion should be taken as a compliment; a society that did not have some of this kind of fighting-blood in it was not of much account.

The society began a series of prosecutions in 1880, shortly after the passage of the law against irregular medical practitioners. Since 1880, the counsel fees and other costs of these prosecutions had amounted to $36,567.39; the fines imposed amounted to $21,585, and the fines collected to $14,160. This left a large annual deficit in this account. Why the profession should be made to bear the cost of prosecuting irregular practitioners of medicine was hard to understand, but he has been informed that if this work were dropped by the society, it would not be taken up by the public prosecutor.

More Members Needed.—Unless more money was at their disposal, this good work must cease. The necessary funds could be procured only by increasing the annual dues or adding five hundred members. He was in favor of holding out the olive branch to those of special schools, providing they would abrogate their sectarian principles, as many of them had already done. The society should also welcome the return of those who left the society many years ago because of a wrangle over the phrasing of a series of bylaws.

Standing Committees.—The following committees were then appointed: *Committee on Ethics*—Drs. Robert A. Murray, *Chairman;* William Balser, Malcolm McLean, Robert Milbank, and J. Lee Morrill. *Com-*

mittee on Hygiene—Drs. J. Henry Fruitnight, *Chairman;* E. S. Bullock, Augustus Caille, Grace Peckham Murray, and Bernard Sachs. *Committee on Legislation*—Drs. Alexander Hadden, *Chairman;* James H. Burtenshaw, Thomas J. Hillis, John B. Huber, Maurice J. Lewi, Charles E. Lockwood, Evarts M. Morrell, Thomas E. Satterthwaite, George F. Shrady, Theodore K. Tuthill, Simon J. Walsh, and Wickes Washburne. *Committee on Prize Essays*—Drs. Simon Marx, *Chairman;* Robert H. M. Dawbarn and George C. Freeborn. *Auditing Committee*—Drs. Robert Campbell, *Chairman;* and Hobart Cheesman.

A Special Committee.—On motion of Dr. Satterthwaite, the following were appointed on a committee to consider the relations of the board of health to the medical profession: Drs. T. E. Satterthwaite, Alexander Hadden, A. Jacobi, H. G. Piffard, and Andrew H. Smith.

On motion of Dr. Piffard, the question of regulating midwives was referred to the committee on legislation, and the other matters alluded to in the president's address were referred to the committee on hygiene.

(Resolutions on the death of Dr. Avery were then adopted, and ordered sent to the medical journals.)

Prize Essay: A Contribution to the Pathogenesis and Etiology of Diabetes Mellitus.—Dr. Heinrich Stern was the author of this essay. The essay will appear in full in a future issue of The Medical Record.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, November 15, 1897.

I. Blake White, M.D., Vice-President, in the Chair.

A Study of the Nares and Pharynx in a Case of Hæmophilia.—Dr. Seymour Oppenheimer read a paper with this title. He said that the case to be reported presented a peculiar symptom group which rendered the classification exceedingly difficult.

The patient was a woman, thirty-two years of age, whom he had first seen in December, 1896. A younger brother had suffered from frequent and copious nasal hemorrhages during childhood, and had been accidentally killed before reaching adult life. The patient herself had been married eleven years, and had one boy, who was in good physical condition. She had enjoyed good health up to five years ago, when she had had "rheumatism of the heart." Four years ago it was noticed that the thyroid gland was increasing in size, but it gave no particular trouble, and medical advice was not sought. Later on she developed exophthalmos, together with almost all of the usual symptoms of exophthalmic goitre. In July, 1896, she first noticed a few small dark spots on her thighs. These disappeared in a few weeks. She then became very nervous and complained of frontal headache, which was relieved by the occurrence of profuse epistaxis. She next had an attack of angina pectoris, which was followed by some indigestion. These attacks were repeated at intervals, and the same succession of phenomena was usually observed. The purpuric eruption usually recurred about once in two weeks. Sometimes the epistaxis and purpura, especially the former, would replace the menstrual flow. All of these attacks came on without apparent exciting cause. A number of times the epistaxis began in the night, while she was asleep. The attacks of epistaxis were prolonged, and in one instance lasted for ten hours. The purpuric spots were not elevated above the skin, and were at first of a pink or red color, gradually becoming black, then yellow, and finally fading away. The eruption was most abundant on the inner surface of the thighs.

When she was first seen by the speaker her appearance was that of a chlorotic patient, and she then had some purpuric spots on her body. The turbinated bodies were found sclerosed, particularly the middle turbinate. After the nose was cleansed a minute ulceration was seen on the left side of the septum, over the situation of the anterior septal artery. The mucous membrane of the septum was congested and macerated, and the septum was thickened. On removing the blood coagula, it was seen that the tissues beneath were the seat of a general sclerosis. There were at this time no petechial spots on these tissues. As a rule, the blood would ooze from the nose, instead of escaping in a stream. In subsequent attacks of epistaxis it was found that the blood seemed to ooze from the inferior and middle turbinated bodies, and from the septum, particularly from the areas covered with cavernous tissue. The bleeding did not come from one or two points, but was comparable to perspiration in the manner of its escape. The hæmoglobin percentage was fifty-eight. As she was a poor woman, she could not be kept in bed and perfectly quiet. The only drugs that seemed to be of any avail were inunctions of the biniodide of mercury and tincture of belladonna, pushed up to twenty minims at a dose. In January the petechial eruption appeared for the first time on the posterior pharyngeal wall. She steadily improved during the spring, the attacks of epistaxis and the purpuric eruptions becoming less and less frequent.

The diagnosis seemed to lie between exophthalmic goitre, purpura hæmorrhagica, peliosis rheumatica, and hæmophilia, although practically it was between hæmophilia and purpura hæmorrhagica. In the latter the bleeding from the mucous membrane, the speaker said, was usually very severe, and was seen in young and delicate persons. This patient was an adult who had been strong and well developed previous to the eruption and the epistaxis. She appeared anæmic only when the attacks of epistaxis were very frequent, and the blood count rapidly returned to the normal. The oozing from the erectile tissue seemed to indicate a marked constitutional dyscrasia, and it was specially worthy of note in this case, because hemorrhage in cases of nasal sclerosis was quite rare. Before the occurrence of the hemorrhage there would be a feeling of fulness in the head, and especially over the bridge of the nose. On several occasions the nasal cavities were inspected shortly before an attack of epistaxis, and it was then found that the tissues became more and more turgid until the onset of the hemorrhage. The blood was watery, coagulated very slowly, and contained a small percentage of coloring matter and a large number of red cells. When epistaxis was the result of a constitutional vice it was likely to be bilateral, in contradistinction to the unilateral hemorrhage so commonly observed when the cause was traumatic.

Nosebleed in General.—Referring to epistaxis in general, the speaker said that shortly before an attack of nosebleed there was not uncommonly a peculiar pruritus, involving especially the anterior nares. This itching was peculiar, in that the scratching did not afford relief, and the pruritus was constant and resisted all the usual remedial measures. In a few cases it had seemed to him to be coincident with an excess of uric acid in the system. In the control of a severe attack of epistaxis he had found it convenient to cleanse the nose with a spray of peroxide of hydrogen under fifteen pounds' air pressure, and then astringents or the cautery could be easily applied if the source of the bleeding was found to be located anteriorly. It had seemed to him that in a general way the character of the bleeding indicated its source. Thus if the blood were bright red, not clotted, and

flowed in a steady stream, the anterior septal artery was probably the source of the hemorrhage. If the hemorrhage occurred in drops, it was probably from the septal or turbinal tissues. If the blood seemed to flow more into the pharynx, it would usually be found to come from the extreme posterior end of the middle turbinated body. Hemorrhage from the pharyngeal mucosa was most commonly due to such traumatism as the lodgment of foreign bodies.

Dr. F. J. Quinlan thought that many even alarming hemorrhages from the nose were purely local, and hence, instead of blindly packing the nasal passages with tampons, the parts should be inspected under suitable illumination, and, if possible, the bleeding point discovered and the hemorrhage controlled. He believed, with the reader of the paper, that many cases of epistaxis were due to reflex or constitutional causes, and sometimes to vicious habits. He had known it to be associated with masturbation and other conditions of genital irritation. Accompanying such irritation it would often be found that the nasal tissues were unduly engorged. Again, adenoid vegetations constituted an important factor in the etiology of the epistaxes of childhood. The part played by atrophic rhinitis had not been especially emphasized in the paper. It was almost instinctive for every person to make an effort to remove anything causing obstruction in the nasal passages, and therefore violent blowing and picking of the nose were often the exciting causes of nose bleed. In these cases there was frequently an atheromatous condition of the vessels which predisposed to hemorrhage. Another source of hemorrhage was an engorgement of the large plexus of vessels at the base of the tongue—that condition which Lennox Browne had denominated "throat piles." This plexus was frequently impinged upon by the epiglottis and the circumvallate papillæ at each act of deglutition. Again, the posterior tips of the turbinated bodies not infrequently became varicose. When this condition was marked, he thought one should hesitate about using a galvano-cautery or any escharotic which might break down the already partially disorganized vascular condition of the parts. The three cases of hæmophilia that he had seen had been traceable to some organic condition—in one case to incipient Bright's disease, in another to cirrhosis of the liver, and in the third to malignant disease. He had never seen a case of pure and simple hæmophilia. There was no better agent for causing a shrinkage of the tissues in the nose than cocaine. This application would, therefore, not only produce anæsthesia, but would diminish the hemorrhage and clear the field for observation. After this had been done, it would be found in probably eighty-five per cent. of all cases of epistaxis that the source of the hemorrhage was the little tubercle of the septum, almost on the floor of the nose, and that it could be easily controlled by pressure with a small pledget of cotton or by touching with a crystal of chromic acid or with nitrate of silver on the end of a probe. The application of the galvano-cautery was sometimes dangerous, because it broke down the already weakened blood-vessels. A great cause of epistaxis was an irregularity of the nasal septum and the consequent obstruction to the return of venous blood.

Dr. J. J. Concannon said that he had treated over one hundred cases of epistaxis, and believed that over seventy-five per cent. of them had originated from the septum. But the hemorrhage usually came from a number of small openings scattered over the septum, so that the application of a crystal of nitrate of silver or of chromic acid would not be sufficient. The cautery was in his hands the most successful application. Some of the worst cases of bleeding he had ever met with had occurred in women at the climacteric period, and the bleeding seemed to come from the middle turbinate in most instances. The application of a ten-per-cent. solution of cocaine would shrink up the parts sufficiently to enable the physician readily to find and control the bleeding point. It would be noticed sometimes that there was an alternate congestion of the turbinates. The books stated that this was a symptom of catarrh, but his experience had led him to believe that it was a perfectly normal condition.

Dr. George Tucker Harrison said that probably more cases of epistaxis were seen by general practitioners than by specialists. In the worst cases that he had met with he had invariably succeeded in controlling the bleeding by packing the nares with iodoform gauze. It was infinitely better than cotton.

Successful Operation on an Enormous Inguinal Hernia.—Dr. A. Ernest Gallant reported a case of inguinal hernia of enormous size upon which he had operated. He said that these cases had formerly been considered inoperable, but two successful cases of this kind had been reported in this city during the past year.

In April, 1895, a woman of sixty-two years had come under his care. She stated that twenty-six years ago she had felt a snap and that something seemed to give way in the left groin. A small protruding mass was noticed, and this mass increased in size with the birth of each of her four children. On several occasions the hernia had become incarcerated, and at the time of her admission to the Lebanon Hospital she was almost bedridden. A photograph was presented showing the condition of the patient before operation. The hernial mass extended half-way down to the knees.

A large incision was made, extending up on to the groin. The hernia was made up of two-thirds of the transverse colon, all of the descending colon, and considerable omentum. The wall of the sac was quite thin. The reduction was very difficult, the hernia being of such long standing and the abdomen quite flat. Sixteen inches of the small intestine was dissected with some difficulty from the lower part of the sac. Owing to the thickness of the ring it did not seem probable that the ordinary Bassini operation would be successful, and he had accordingly stitched the internal oblique, transversalis, and peritoneum to the inside of the abdomen, just at the angle of Poupart's ligament, and had then stitched the layers of Poupart's ligament to the external oblique and the fascia above, and had closed the skin. The skin incision reached down to the lower part of the labium majus and up for a distance of twelve inches.

Dangerous Distention of Bowel Relieved by Massage.—The patient rallied fairly well from the operation, but on the second day there was considerable distention of the bowel. She was given a saturated solution of Epsom salts at short intervals, and also enemata, but without result, and on the third morning he had been notified that the patient was suffering from intestinal obstruction and that an operation seemed to be demanded. The speaker said that in July, 1896, he had published a plan of treating cases of intestinal distention, which consisted in removing the dressings and applying systematic massage over the colon. This procedure was tried in the case under consideration, and in a few minutes a gurgling in the bowel was heard. The pain rapidly diminished, so that the massage could be carried on with more pressure. After about fifteen minutes there was a sudden explosion of gas, and from that time on the patient steadily convalesced. After leaving the hospital this woman was able to do washing and ironing, and attend to her household. He had seen her last in March, 1897, and she had then been in excellent condition. The result seemed to him specially satisfactory in view of the fact that this woman had been an invalid and bedridden for many years. He believed the good result to have

been due to the method of suture and also to the simple and ready method by which the great distention of the intestine had been relieved without further operative interference. Dr. Gallant said that about six weeks ago he had done a hysterectomy, and had had to remove two inches of the abdominal wall because of extensive cicatricial tissue. Within forty-eight hours the patient began to suffer a great deal from abdominal distention. She was subjected to this massage for fifteen minutes, with marked relief and benefit. The first case in which he had tried this method had been one in which the distention had existed for five days. After twenty minutes' rubbing the gas had been passed freely, and the patient had gone on to recovery. In addition to performing massage in this manner, the patient should be turned on one side to favor the escape of the confined gas. Cathartics did not meet the indications in these serious cases, but this simple method would be found both safe and effective.

Useful Genito-Urinary Instruments.—Dr. Ferdinand C. Valentine exhibited a number of genito-urinary instruments, which he said would be found as serviceable to the general practitioner as to the specialist. The first one was a convenient modification of the Guyon syringe. The second was a French urinal, so constructed that the distal end of a retained catheter was kept constantly immersed in an antiseptic solution, and the urine overflowed from time to time into a larger compartment. The third instrument was a modification of his own apparatus for irrigating the urethra and bladder. He had found it more convenient to substitute a metallic shield for the glass one. The soft-rubber tubing from the reservoir now passed through a split metallic tube, and by simply sliding a ring back and forth this split tube was made to expand and contract, and by pressure on the inclosed rubber tubing it perfectly and delicately controlled the flow of fluid through the latter. This modification had been found a very decided improvement on the older form of stopcock used with this apparatus.

ROYAL COLLEGE OF SURGEONS, ANNUAL MEETING—ANOTHER UNIVERSITY SCHEME—M. CALOT AT THE CLINICAL SOCIETY, HIS TREATMENT OF POTT'S DISEASE—MEDICAL SOCIETY, CRETINISM, COLEY'S INJECTIONS—JUBILEE OF ANÆSTHESIA—THE TYPHOID EPIDEMICS THE LATE SURGEON O'GRADY—DEATH OF DR. CAGNEY—ROENTGEN SOCIETY.

London, November 1, 1897.

Sir William MacCormac, as president, took the chair at the annual meeting of fellows and members of the Royal College of Surgeons yesterday afternoon. He pointed out some of the more important items in the report of the council, most of which have been mentioned in this correspondence as the matters to which they had reference occurred. He also defended the statement issued on the occasion of the plebiscite of fellows as to the representation of members. This question was now brought before the meeting in distinct resolutions, on which the speeches resembled many that have gone before. By twenty-three to two a resolution was carried to the effect that the recent vote of fellows cannot be regarded as a final expression of opinion. Then by thirty-seven to one the meeting repudiated the claim of the council to represent the members as well as fellows, and demanded the franchise for members.

The meeting then considered the question of medical-aid societies, on which the sister college in Dublin has recently issued a statement against those who accept office under disgraceful conditions. Whether the corporations generally will follow remains to be seen.

A movement has been going on for some time to organize a teaching university, and a fresh scheme is about to be launched. It is a federation similar to that which failed to secure the indorsement of Parliament. It would leave the University of London as it is, and be itself a teaching one only. It is proposed to call it the University of Westminster. The weak point appears to me to include a faculty of theology. It may not be easy to get the government to adopt so risky a proposal.

Dr. Calot met with a reception by the Clinical Society which ought to disperse any doubts he may have entertained as to the cordiality of English professional feeling. There was a good audience to welcome the pioneer of the revival of a mode of treatment of Pott's disease by immediate reduction of the deformity, and even those who had most misgivings as to the value of the method were as hearty in their reception as those who were quite convinced. Messrs. Jones, Tubby, and Murray all had cases to relate, but as the discussion was adjourned I will postpone any consideration of this to make room for some of M. Calot's remarks, who spoke in French and was listened to with close attention.

He said that in treating Pott's disease the sole object he had was to correct the deformity. To attack the palsy or congestive abscess is to change a disease which has ninety-five per cent. of cures to one with ninety-five per cent. of deaths. The prudent surgeon's attitude was that observed in knee or hip disease. Hitherto the results of immediate reduction had been very favorable and he looked for further improvement in the future. Out of six hundred cases, of which notes had been furnished him from various countries, the fatality of one per cent. might compare well with other recognized operations. If, besides, he had met with three cases of paralysis following operation, it should be remembered that in Pott's disease paralytic complications occur in about one in five cases. Further, he had eight cases in which paralysis was relieved by his operation. The following cases were not suitable for the treatment: children in an advanced state of cachexia, those suffering from cough, those with congestive abscesses or with fistulæ, and those with hunchback of long standing which resist traction of from fifty to eighty kilograms.

M. Calot then detailed the treatment he adopts in cases of long-standing ankylosed deformity. Though it is possible, he holds, to reduce them by traction, it is more surgical to lay bare the adhesions and proceed to break them down by a plan varying with their position. Remote accidents, M. Calot said, are less to be feared than after-operations on the knee. When there is default of union, the latter can be brought about artificially by denuding the laminæ at the parts where they are in contact, and placing periosteum over the point of desired junction. He had provoked artificial union on ten occasions and was half inclined to recommend it as a routine procedure. The plaster apparatus he uses was then described. It is left on from three to five months if the child is doing well, and may have to be renewed once or even twice. The ultimate duration of treatment varies. In acute cases it is the duration of Pott's disease itself, one or two years; in curvature representing a past Pott's disease it might not be more than from four to eight months.

At the Medical Society's meeting Dr. Colman showed a girl of nine and a half years as an example of partial cretinism. She was just three feet high and weighed only two stones two pounds. Stunted growth, absence of any accessible thyroid, fat mases in the anterior tri-

angles of the neck, thick lips, and puffy eyelids were the signs of cretinism. Lordosis and prominent abdomen were also observed when the girl came under notice last June. There was, however, entire absence of the usual nervous symptoms, and the girl was intelligent, bright looking, and had reached the second standard at school. She was put on three grains of dried thyroid extract, and in the four months has grown two and a half inches, and her appearance has become less characteristic. Dr. Colman suggested there might be an accessory thyroid which sufficed for the nutrition of the brain but not for the body. The president remarked that there might be other cases of partial cretinism which it would be well to observe and treat with thyroid.

Dr. Carr showed a girl who had lost what he described as the typical cretinoid appearance which she presented in February, 1896, when she was five years old. Treated with thyroid she now presents a healthy aspect, goes to school, and gets on there. Her weight has increased from twenty-four and a half to thirty-seven pounds, and her height from thirty to thirty-seven and a half inches.

At the same meeting Mr. Mansell Moullin showed two cases in which inoperable tumors had, he said, almost disappeared after repeated injections of Coley's fluid. One tumor was in the groin, the other in the abdomen. They were considered sarcomatous, but there was no proof of their nature. They were certainly not gummata. If they had been inflammatory, they would almost certainly have suppurated. Mr. Cheyne remarked that the treatment seemed only to benefit spindle-celled sarcomata. Dr. Colman said he had examined two tumors post mortem, one ten days after Coley's injections, the other ten months after. In the first he found a cavity containing two drachms of yellow fluid, composed of broken-down cells; in the older case an ordinary cicatrix at the site of injection.

The Society of Anæsthetists held a *conversazione* last night to commemorate the jubilee of the introduction of anæsthesia. A number of interesting exhibits connected with the subject were shown, among which perhaps the most noteworthy were those of Mr. George Foy, of Dublin, whose "History of Anæsthetics" will be familiar to some readers.

The epidemics of typhoid, although diminishing, are still occupying our serious attention. In Maidstone the number of cases notified has reached 1,848, with some 130 deaths. At Lynn the medical officer of health reports that there has been exaggeration in the papers, and there is an abatement of the epidemic, only one death having taken place this week. But the total cases have reached 406, a large number out of a population under 19,000, and another death occurred yesterday, being the thirty-fifth. The Belfast report is 13 new cases for the week. At Clifton the plague seems stayed, but has affected 200 people and killed 15. Smaller outbreaks are reported in other directions, which it is hoped may be circumscribed.

Sir George Duffey, president of the Royal College of Physicians, Dublin, took the chair at an influential meeting, at which it was resolved to raise a memorial to the late Surgeon O'Grady.

James Cagney, M.D., A.M., etc., physician to the Hospital for Epilepsy and Paralysis, and electro-therapeutist to St. Mary's Hospital, expired yesterday morning from cardiac failure, in the course of an attack of typhoid. He held a number of other appointments, had contributed numerous papers to societies and journals, and translated Erb's "Electro-Therapeutics."

The Roentgen Society has had a successful *conversazione*, when Prof. Sylvanus Thompson, F.R.S., presided and spoke of the value of the rays in medical work. He also commended the secretary, Dr. David Walsh, and spoke of his book just issued on the subject in appreciative terms. Dr. Walsh is an enthusiast in the new science and physician to the Western Skin Hospital.

OUR PARIS LETTER.

(From our Special Correspondent.)

MEDICAL PARIS IN FULL SWING—REACTION CAUSED BY TOO STRINGENT LAWS—RE-ADMISSION OF FOREIGN STUDENTS—HIGH MORTALITY RATE FROM TUBERCULOSIS IN THE FRENCH ARMY—DEATH OF DR. EVANS—DECREASE OF CRIME, ETC.

PARIS, November 27, 1897.

MEDICAL Paris is again in full swing, the Place de l'École de Médecine is once more crowded with students hurrying to and fro to the various lectures, and one meets at every turn the carriages of professors and general practitioners dashing through the city to visits or consultations, or on their way to their services at the hospitals.

The reaction of the excessive and almost draconian laws, regarding the matriculation of foreign students at the Faculty of Medicine of Paris, has begun. It will be remembered that some years ago a too great number of foreign students matriculated at the faculty, and from this resulted an overcrowding to such an extent that the general council of the faculties was obliged to have recourse to certain measures; among others, that of sending provisorily a considerable number of the foreign students to medical faculties in the provinces. The general council of the faculties seems to have become convinced of the apparent harshness of this measure, and to have relented, for the necessary dispositions have been taken to re-establish the old order of things. The council of the University of Paris has decided that from the present academic year foreign students may be matriculated as in the past at the Faculty of Medicine of Paris. This is in my opinion a wise measure, and should be followed up by a relaxation of the restrictions affecting those who are already physicians and desire to practise in France—a free and republican country.

The tables of medical statistics of the French army for the year 1895, published by the minister of war, show that the general mortality of the army is augmenting every year; from 6.19 per thousand in 1893 to 6.26 per thousand in 1894, it reaches 6.86 per thousand in 1895. It is to the mortality from grippe that this augmentation in the total number of deaths is partly due. Every year since the pandemic of 1889–90, the army has had to pass through an epidemic of grippe; but, while the mortality from that disease was 50 per thousand in 1890, it attained 130 per thousand in 1895—that is to say, a figure almost three times as high.

But what gives most cause for reflection and alarm is that the number of deaths from tuberculosis is continually augmenting; for instance, 162 per thousand in 1893 and 1894, against 165 per thousand in 1895; from the tables of statistics the annual total mortality rate of the French army from tuberculosis may be fixed at 10 per thousand. This is doubtless due to a variety of causes, such as probable bad hygiene in barracks, the exposure of a soldier's life even in time of peace, heredity, overwork, etc. Nevertheless, taking into consideration the fact that an outdoor life is generally conducive to health, especially when coupled with exercise such as is had in military service, this high mortality from tuberculosis is, to say the least, remarkable, and no wonder that it is attracting professional attention. There are many pros and cons in the case, and it is impossible in the short space of one letter to go at all into the etiology. I am satisfied, however,

that, speaking generally, besides all the causes which favor the development of the bacillus of Koch, absinthe drinking and the almost universal habit of cigarette smoking—which, be it said *en passant*, is the very worst form of using tobacco—play a greater rôle than is usually admitted, not only in favoring the development of phthisis, but often as a direct causal factor.

By the death of Dr. Thomas W. Evans, probably the greatest dentist of our day has passed away. Dr. Evans, although never engaged actively in the practice of medicine, followed a regular course at the Jefferson Medical College of Philadelphia, of which city he was a native. During the Franco-Prussian war of 1870, at its very beginning Dr. Evans took great interest in sanitary matters, and was largely instrumental in organizing and establishing the American ambulance; and I well remember my visits to it on the old Avenue de l'Impératrice, just beyond the Arc de Triomphe. The doctor subsequently published a work on the subject. It was at this time that Dr. Sims took command of the Anglo-American ambulance, and left with it for the front, where it did such good service, especially during the battle of Sedan. Both of these ambulances were parts of the great Red Cross Society. Dr. Evans' wealth and success were due, first, to a natural mechanical genius, and to the influence which he obtained in higher circles during the second empire. By advice from those quarters he was enabled to make judicious purchases of real estate.

In Paris they are rather dilatory about publishing statistics. Those of the army mortality for 1895, mentioned above, are just out, as are also those of criminal justice, in which legal medicine is almost always so much interested. The report of the "keeper of the seals," which appeared a week ago, is satisfactory. According to this, for the first time in many years there is an important diminution, not only in the number of actual crimes committed in France, but in that of misdemeanors as well. The report goes back fifty years, during which period there has been a steady decrease in the number of murders by poison—thanks to the progress made in chemistry and legal medicine; parricides have also decreased.

Dr. Quinton, at the last meeting of the Biological Society, reported a rather novel experiment, as follows: "In order to confirm my hypothesis of the great value of sea water to the higher organisms, I practised on the dog intravenous injections of that liquid in extremely large doses; the animals got, effectively, in eight hours, sixty-six one-hundredths and even as much as eighty-one one-hundredths of their weight of sea water, and that without presenting the least accident." Why could not sea water be injected in the human subject as well as artificial serum?

"CURE" IN TUBERCULOSIS.

[illegible]

SIR: I read with a degree of interest Dr. Bogardus' remarks in your issue of November 13th, about the promiscuous use of the word "cure" in connection with the various remedies for tuberculosis. He is right. The use of the word needs qualification. Whether it be in connection with "tuberculin" (tuberculocidin, antiphthisin), or "serum," or "antitoxin" (by the way, another word that needs definition badly), etc., the word "cure" becomes almost bitter sarcasm in the face of the negative results that, candidly, have to be recorded.

As long as we have to deal with the condition that mixed infection presents, and there are at least ninety cases out of a hundred, I am afraid we shall not be able to effect a "cure" in its absolute meaning; not, at any rate, until we know more about the cell life, or until the inherited power of resistance comes to our aid in becoming so developed as successfully to resist the *casus belli* from the very outset. The first contingency is possible, the last one probable; but it will require generations of hygienic and sanitary prophylaxis. But, even so, it points out to us the fact, reinforced by the failures of the past, that the battle must be fought along nature's lines. To develop the power of resistance means to develop the general vitality, and the *rationale* of this must lead us to climatic treatment and hyperalimentation, supplemented, according to circumstances, by an auxiliary remedial one. And that is all medication possibly can be, that is, auxiliary. I mean, too, medication along general lines. "Specifics" should be tried on the dog.

The letter of Dr. Bogardus does not lead me to make any remarks about the climatic treatment or hyperalimentosis, but about the remedial one; so much the more, as I am perhaps, to a certain extent, responsible for the introduction of intratracheal medication by means of a syringe, not catheterization. Of all the methods of administration, I have in my particularly varied experience with tuberculosis found intratracheal medication, that is, more properly speaking, intrabronchial injection, the best. In the first place it does not interfere with the process of digestion. Whether it be with menthol, or guaiacol, or iodine, or iodol, etc., I know I bring the remedy *in situ*, right into the bronchus, from where it slowly diffuses throughout the lung tissue—the shortest cut to the spot of lesions. I am more sure the chemicals reach there in an undecomposed state than by way of the œsophagus; for Heaven only knows what metamorphosis they undergo in contact with the ferments and saline constituents of the alimentary tract. The operation of the syringe is easy; not difficult to learn after a few experiments, preferably on charity patients. And, best of all, there is as a rule immediate relief, not achieved by common expectorants, especially observable in the enervating, harassing, hacking cough of tuberculosis. Oftentimes I have been able to eliminate quickly by means of this intrabronchial injection asthmatic and pneumonic complications, and more often an underlying subacute bronchitis, with a corresponding improvement in the general aspect of the tuberculosis.

And one more word about "cure." With special reference to tuberculosis, considering its tendency toward the deadly triple alliance with the streptococcus and staphylococcus, if we, by means of any rational treatment, fight them to a standstill, even for a time—in other words, secure a postponement of death—we may well, at the present time and with our present knowledge, employ the word "cure" in a relative sense; and I believe that is the way most physicians take it in this connection.

JOSEPH MUIR, M.D.

234 WEST THIRTY-FOURTH STREET, NEW YORK, November 21, 1897.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 4, 1897:

A CONTRIBUTION TO THE PATHOGENESIS AND ETIOLOGY OF DIABETES MELLITUS.[1]

BY HEINRICH STERN, M.D.,

NEW YORK.

I. Introduction.—Since Claude Bernard's ingenious experiments nearly five decades ago, it has been the endeavor of physiologists and observers to ascertain the pathogenesis and etiology of diabetes mellitus. The great number of diverse theories which thus have been advanced did in no way produce a clear conception of the true origin of this affection. Even the character and the course of this disease are ill-defined, and true diabetes mellitus, which alone I shall discuss in the following, is thought to be identical with a more or less complicated grave type of glycosuria, for the absence of glucose from the urine, or its disappearance from it, is deemed by even the latest writers and investigators the *a-priori* fact of the non-existence of diabetes mellitus.

In the writer's opinion, however, diabetes mellitus —that is, what is understood by this term to-day—is not a disease *per se*, but only implies a single stage in the course of a specific and general somatic deterioration. It does not occur as a definite and independent affection, but is the result of deteriorating processes, and in its course gives again rise to other symptoms and conditions. This diabetic glycosuria—which is wrongly styled diabetes mellitus—has its prodromata and its initiatory symptoms, its continuations, and subsequent conditions. In short, diabetes mellitus, as defined by others, is indicative of only one stadium of the general diabetic or glucose-generic deterioration.

The diabetic deterioration from the physiologico-chemical as well as from the clinical standpoint, may be divided into three great stages: First, the prodromic or preglycosuric stage; second, the period of glycosuria (the diabetes mellitus of to-day); and third, the postglycosuric stage or the period of auto-intoxication.

The preglycosuric stadium comprises a variety of disturbances which only of late have been recognized and pointed out as prodromata of diabetic glycosuria. This prodromic stage tends to show that what is called diabetes mellitus does not occur independently, but is preceded by a chain of more or less pronounced symptoms and conditions which are indicative of a general deterioration. The second stage—the glycosuria—offers a most characteristic and marked symptomatology, and therefore was always thought to be a separate and distinct disease, to which the term diabetes mellitus was applied. I consider the glycosuric stage the transitory period of the diabetic deterioration, as it is the forerunner or premonitory factor of the third stadium of this deterioration, the stage of auto-intoxication.

The duration of the third or postglycosuric stadium varies greatly in different persons. It may be persistent, especially in its lighter manifestations, for months before toxicosis is complete, but I have seen a few cases in which the condition of perfect auto-intoxication developed to all appearances within an hour's time, when the death of the patient ensued. This stage does not exclude glycosuria completely, but is always characterized by a diminished flow of saccharine urine with the presence of dimethyl-ketone in excess, of ethyl-diacetic, and of lævorotatory oxybutyric acids. In addition thereto, the present writer thinks that he has of late succeeded in identifying an abnormal chemical substance in the blood of diabetics who have died in a comatose condition. A conclusive statement, however, about his observations he deems somewhat premature, and beyond the scope of this treatise.

The so-called true diabetes I therefore designate as diabetic glycosuria, or the glycosuric stage of the diabetic deterioration.

All other varieties of glycosuria have nothing in common with the diabetic deterioration. They are without exception secondary disturbances which almost always pass away when the primary affection has disappeared, and are therefore more or less transitory in character.[1] They may occur as sequelæ of a number of diseases, of traumatosis, of hyperneuria and excessive nervous irritability, of childbirth, of operations, of different forms of alimentary disturbances, or as the result of hyperingestion of sugar or other carbohydrates, of the introduction of irritating substances, and of the administration of certain drugs, as strychnine, curare, and phloridzin ($C_{21}H_{24}O_{10}.2H_2O$).[2]

II. Pathogenesis of True Diabetes.—Pavey, from the standpoint of physiological chemistry, holds the liver responsible for the diabetic condition. In normal digestion the carbohydrates, he explains, are converted into maltose and not into glucose, dextrin being intermediate in the process. Maltose is absorbed and assimilated as such, and stored away as glycogen. When pure glucose is introduced into the stomach, he continues, it will readily be converted into maltose, under the influence of a special glucose ferment during gastric and intestinal digestion. This ferment can exist only in healthy venous blood. In the diabetic state, however, the blood enters the circulation of the liver in a condition of insufficient deoxygenation, thus giving rise to the production of a glucose-creating ferment. This imperfect dearterialization Pavey explains as due to vasomotor paralysis, especially of the vessels of the chylopoietic system. The glucose thus formed is an abnormal product, and, not being capable of assimilation, enters the circulation and makes its appearance in the urine.

The fact that carbon dioxide outside the body may retard the conversion of glycogen into glucose was utilized by Ebstein, when he advanced his explanation

[1] Being the prize essay read before the Medical Society of the County of New York, 1897.

[1] The primary affection, on the other hand, may be followed by a permanent disorder or structural change, and thus a chronic glycosuria, or conditions which favor or cause even diabetic deterioration, may be the consequence.

[2] Phloridzin is a crystalline glucoside which has been employed in the treatment of glycosuric conditions. Phloridzin diabetes, which is produced by overdoses or prolonged administration of the drug, is considered by many investigators a type of true diabetes, to which I cannot agree, as the disappearance of this form of glycosuria, almost in every instance, ensues soon after the withdrawal of the phloridzin or the diminution of its dose.

of the origin of diabetes, which ignores any local cause. His view is, in short: The protoplasm of the diabetic organism has an inherent defect, and varies from that of the healthy body; that from a known quantity of carbon-containing matter it forms less than the normal amount of carbon dioxide. The conversion of glycogen into glucose becomes inordinate—that is, larger quantities of the latter are produced, as the necessary amount of carbon dioxide with its retarding factors is not present in the diabetic state.

Cantani agrees that the body produces less carbon dioxide in diabetes than normally. He considers this, however, the result and not the causative factor of the affection. He is of the opinion that the carbohydrates are directly utilized in the animal economy, and does not believe that they are converted into glycogen and as such deposited in the muscles, liver, and other organs. He draws the conclusion that, if the saccharine and starchy ingesta had to be first converted into glycogen and then into glucose before the latter makes its appearance in the urine, the time left for such a conversion would be entirely too short.

If in the late stadium of diabetes a given quantity of sugar is administered to a patient, exactly the same amount of sugar may be obtained again in the urine, and it is unlikely that this would happen, Cantani says, if the sugar had to be first concreted into glycogen and then again into glucose. If the latter were the case, some of the sugar ingested by the patient would certainly remain in the system and be retained there as glycogen.

Lépine,[1] after numerous researches on the relation of pancreatic disease to diabetes, is of the opinion that the healthy pancreas normally produces a ferment which enters the blood through the lymph current. He assumes that this ferment, which after Nommès[2] he called "glykolysin," is effecting the dissolution of the saccharine substances in the system. The non-presence of this ferment in the blood he supposes to be the cause of diabetes.

In framing his theory Lépine started from the fact which had been first noticed by Claude Bernard, that the sugar disappears from drawn blood, attributing this disappearance to the action of the ferment which originates in the pancreas. The glycolytic ferment, he further assumes, is greatly reduced in blood drawn after the extirpation of the pancreas and in that of diabetics.

Seegen,[3] who after a number of experiments maintains that the liver produces sugar from albumin and fat and glycogen out of carbohydrates, when reflecting on Lépine's hypothesis about a glycolytic ferment of pancreatic origin, the absence of which would cause accumulation of sugar in the blood, makes the following point: Admitted even that the blood of diabetics possesses less glycolytic action than that of a healthy person, it need not follow that this indicated the presence during health of a special glycolytic ferment produced by the pancreas. (He observed that normal glucose will disappear rapidly from freshly drawn blood when the latter is kept at a temperature of 39° C., while a current of air is passed through it. To prove that the disappearance of the sugar was not due to the activity of the protoplasmatic substance, he killed the latter by adding chloroform. This made but a slight difference in the glycolytic action.) Seegen further remarks that, since the glycolytic activity is increased upon standing of the drawn blood for some time, the ferment may be produced rather by some alteration in the blood outside the body than by the pancreas, and argues that the blood in diabetes may contain something preventing glycolysis, so that, even if Lépine's experiments are correct, they do not necessarily indicate a diminution of the glycolytic ferment in the diabetic state.

Besides Lépine, a great number of investigators have made observations as to the relationship of the extirpation of the pancreas or pancreatic disease to diabetes mellitus. I mention only de Dominicis, Hédon,[1] Thiroloix,[2] Gley, Harley, Cappareli, von Mering and Minkowski.[3] The latter two especially have given a great deal of attention to this problem. Minkowski, speaking on the causes of diabetes after the extirpation of the pancreas, says, in short, the following: There is no doubt that the occurrence of experimental pancreatic diabetes is the result of certain disorders in the system, due to the removal of the pancreas. The nature of these disorders, however, cannot be told with any degree of certainty as yet.

In dogs and other animals, after the extirpation of the pancreas, grape sugar, that which is ingested as well as that which has formed in the system, is not utilized in a normal manner, and the deposition of glycogen in the liver does not occur normally. It may be assumed that there is a dependency between these phenomena. After removal of the pancreas there happens either an accumulation of something abnormal in the system, or a normal function disappears. That is, either the pancreas has normally the function to remove a ferment-like or toxic substance, whose retention in the system causes the elimination of sugar; or it is a normal function of the pancreas to effect the consumption of the sugar in the organism, and the deficiency of this function is the cause of diabetes mellitus.

The abnormal accumulation of sugar in the blood in pancreatic diabetes is undoubtedly the cause of its passage into the urine. It is easy to assume the substance, circulating in the system, which through abnormal formation of the sugar produces the accumulation of the same in the blood. Some observers have maintained that the next result of the removal of the pancreas is the conversion of glycogen by a saccharifying ferment, others assume that an increased waste of tissue material is the direct consequence.

More plausible, however, is the assumption that the pancreas has to perform a specific act normally regarding the consumption of sugar, and that the disappearance of this function means the causation of diabetes.

A satisfactory theory as to the genesis of pancreatic diabetes, however, cannot be propounded at this date. Two points, though, every hereto pertaining theory must consider: that is, the peculiar behavior of the glycogen of the liver, and especially the different destination of dextrorotatory and lævorotatory glucoses.

Minkowski says: "There are two assumptions which force themselves upon us as to this matter, although I cannot vouch definitely for either of them. First, the conversion of dextrose into glycogen is a necessity for the normal consumption of sugar. This conversion can occur only with the aid of the pancreas, which exerts a specific action either upon the dextrose itself or upon the cells of the liver or those of the muscles. It has to be further assumed that the formation of glyco-

gen from lævulose is brought about independently from any pancreatic influence. It is difficult to state how the latter could happen. The most simple explanation is the presupposition that glycogen can be manufactured only from lævulose, and that it is the duty of the pancreas to convert dextrose into lævulose. Such an assumption, however, is hardly admissible. Second, normally sugar is consumed directly as such. The aid of the pancreas, though, is essential to the normal consumption of dextrose. The formation of glycogen is not directly impaired after the extirpation of the pancreas. The disappearance of the glycogen in the liver is only the consequence of the inordinate consumption of sugar. Glycogen, whether manufactured from albuminous material or from ingested grape sugar, continues to be converted directly into dextrose, which accumulates in the blood and makes its appearance in the urine. Pancreatic assistance is not necessary for the consumption of lævulose. The latter, therefore, even after the removal of the pancreas, may be used to some extent. The supply of lævulose satisfies the demand for sugar in the organism. The oversupply of lævulose may be deposited as glycogen. If grape-sugar should result again from this glycogen, then it will be transmitted unaltered to the urine. The increase of grape-sugar elimination after the supply of lævulose is also explainable in this manner.

"The pancreatic function does not necessarily depend upon the production of a 'glycolytic' ferment. The pancreas could influence, somehow or other, those organs which normally consume sugar, setting free therein certain affinities that would attract the sugar molecule. It may be further conceivable, for instance, that the sugar normally circulates in a loosely bound combination which prevents the influence of the oxidizing processes upon it; and that it is the mission of the pancreas to split up this combination, thus furthering the normal oxidation of the sugar."

III. The Author's Observations.—It is evident that the artificial conditions produced in the normal organism for the purpose of experimental research do not effect in every respect an exact reproduction of that pathological state which the investigator seeks to procure. This is especially the case in artificial diabetes. Though it is the truth that we find the whole symptomatology of the second and third stage of diabetic deterioration in experimental pancreatic glycosuria, we must never forget that the latter is the result of the extirpation of the pancreas, and that this fact alone is certainly not analogous with the condition in true diabetes. I further maintain that observations and their consequent deductions, drawn from artificially created bases, are, if at all, only in part applicable to those conditions originating from naturaliy contracted bodily affections, and that the theories as to the genesis of a pathological statement, if based solely upon artificial experimental disease, prove to be often useless, inefficient, and at times even misleading.

Thus I have abandoned experiments with animals in all instances when a certain disease has first to be produced by artificial means, and when it is of greater importance to determine the causative factor or factors underlying the generative processes than to explain mere secondary phenomena or symptoms arising during the course of these processes.

The great divergency of opinion as to the causes of diabetes is undoubtedly the result of too much indiscriminate experimenting on animals. Salivary glands, duodenum,[1] thyroid gland,[2] and other morphological parts were removed from animals to find the cause of the glycosuric symptom.[3] The constant repeating of such experiments, "the re-proving," I deem entirely uncalled for. Moreover, I verily believe at this day that a glycosuria may follow the removal of any vital organ, provided the animal is capable of surviving a sufficient time.

The following observations—more or less experimental in character—were made on patients whose affection I recognized as diabetic deterioration.

In tabulating the history of these six cases I have abstained from enumerating all such incidents as are inessential to the following considerations. This pertains not only to other products of metabolism which occurred normally or abnormally in the urine and the fæces, but also to the duration of the different cases. It was my endeavor to bring forward only the most typical period of the second stage of diabetic

CASE I.

Patient was not seen by me since last year, when he left town.

[1] De Renzi and Reale (Verhandlungen des X. internationalen Med.-Congresses zu Berlin, 1890, Bd. ii., Abth. v., S. 97) experimentally removed the salivary glands and the duodenum from a number of dogs, and assume that a type of true diabetes would follow either operation.

[2] Falkenberg ("Zur Exstirpation der Schilddrüse," Verhandlungen des X. Congresses für innere Medicin, Wiesbaden, 1891, S. 502) believes he has observed a true and chronic diabetes after the extirpation of the thyroid gland.

[3] The experimenting with a number of drugs, whose administration may be followed by a glycosuric condition, naturally belongs thereto.

Status præsens: Patient is afflicted with secondary affections and is laid up, more or less; glycosuria and azoturia persistent, though the percentage of glucose and urea is rather small.

deterioration with its most typical chemical phenomena.

For obvious reasons I have not analyzed the fæces so frequently as the urine, but this must not be construed as if the patients were afflicted with obstipation in the intervals between the examinations.

Urea, biamide of carbonic acid, or—

Carbamide, H O H

$$H\text{-}N\text{-}C\text{-}N\text{-}H, \quad =CO(NH_2)_2$$

is one of the most simple amid bodies and the main product of the oxidation of nitrogenous substances in the system. It occurs in the urine generally in from 1.5 to 2.8 per cent.; in the blood, the fæces, the lymph, the perspiration, the crystalline lens, and the aqueous and vitreous humors of the eye normally in traces only.

It is the general opinion among physiologists and clinicians that the amount of carbamide excreted is dependent upon the quantity of nitrogenous material ingested. Lehmann,[1] experimenting on himself, found:

Kind of Nourishment.	Quantity of Urea Excreted per Diem.
Mixed	32.5 gm.
Animal	53.2 "
Vegetable	22.5 "
Non-nitrogenous	15.4 "

If no nourishment is taken, carbamide continues to

Status præsens: Patient is at a European spa; the diabetic deterioration is progressing.

be excreted, though in lesser quantity, indicating that it is derived from another source than the direct decomposition of proteid ingesta. Thus carbamide is one of the products of retrograde metamorphosis of the plasmatic tissue constituents.

The excretion of carbamide becomes of pathological significance only when it occurs in diminished or excessive quantities. It indicates thus a disturbed metabolism, either retarded or increased plasmolysis. The quantity of excreted urea is proportionally small in diseases of the liver, in cachectic conditions, in different renal affections, and is diminished in fasting; its elimination is noticeably increased after muscular or mental strain, and in the febrile states, when it usually increases in proportion to the intensity of the fever. It is excreted in excess in diabetes mellitus, which phenomenon all observers ascribe to the great consumption of albuminous food.

It is very difficult, however, to determine with any degree of certainty what constitutes an abnormal production and excretion of carbamide. Moreover, the production of urea is not in every instance followed by its speedy or complete elimination; partial retention of some urea—by its reabsorption—is in my opinion much more frequent than is usually supposed. The ingested albuminates cannot serve as a basis for the exact determination of all the produced urea. We may determine the amount of nitrogen ingested, also possibly that which is excreted; the latter, however, by no means represents closely or accurately the nitrogen of the proteid nourishment. In all our calculations the retrograde tissue metamorphosis ought to be taken into due consideration, and, although a great many achievements and discoveries have been accomplished in other fields of scientific research, we have not succeeded as yet in determining that elementary point which is essential (as a basis) for the exact estimation of tissue waste.

Status præsens: Patient attends to his business; is emaciated and very irritable; glycosuric stage persistent; glucose in varying amounts; nitrogen rather steady.

As a matter of convenience only, we may define the diminished excretion of urea as the retention of ingested nitrogen[1]—that is, more nitrogen is introduced into the system than is eliminated, and we may define the excessive excretion of carbamide as an increased plasmolysis of the living tissues—that is, a much greater amount of nitrogen passes out of the system than has been ingested.

I now draw your attention to the tables.

Case I.—From April 17, 1895, to April 29, 1895, the patient was under strict albuminous diet. The daily average of ingested albuminates I calculated as 185 gm. The nitrogen contained in albumin is 15.6 per cent; the ingested nitrogen therefore amounted to 28.86 gm. daily. The average daily quantity of voided urine during this period amounted to 3,002 c.c. The average daily quantity of urea excreted by the urine amounted to 3.2 per cent.; that is, 96.1 gm. The amount of urea in the fæces on April 29th was 1.3 gm., that is the total excretion of 97.4 gm. of urea in twenty-four hours.

Urea contains 46.73 per cent. of nitrogen. The total of N excreted during twenty-four hours amounted therefore to 45.51 gm.

Consequently 16.65 gm. of N more was excreted than ingested.

From May 4 to May 11, 1895, the patient was under a diet greatly abundant in non-nitrogenous material. He voided during that time on the average, 2,415 c.c. of urine *per diem*, containing in the mean 5.5 per cent. of urea, which is 132.82 gm. Examination of fæces on May 10th revealed the presence of 4 per cent. of urea, or 1.52 gm. Under the influence of non-nitrogenous nourishment he therefore excreted on the average, 134.34 gm. of urea daily; that is, 62.78 of N.

On May 18, 1895, for investigation as well as for therapeutic purposes, I kept the patient fasting for seventeen hours, allowing him only a moderate amount of water during that time. He voided in twenty-four hours (counting from the start of the non-ingestion until about seven hours afterward) 1,850 c.c. of urine, containing 3.8 per cent. of urea; that is, 70.3 gm. During that period the solid residue of his fæces amounted to 21.5 gm. and contained 1.3 per cent. of urea, or 0.3 gm. Within the time of fasting and the seven following hours, the patient therefore excreted 70.6 gm. of urea, which equals 33 gm. of N.

Case II.—From December 28, 1895, to January 4, 1896, the patient lived on mixed food. The amount of proteid matter therein contained was not ascertained by me. In this time she voided 1,380 c.c. of urine on the average daily. The percentage of urea in the mean therein contained was 3.4 per cent., or 45.92 gm., indicating 21.45 gm. of excreted N.

From January 6, 1896, to April 13, 1896, the patient's nutriment was exclusively albuminous, consisting of about 200 gm. of proteid matter on the average daily. That is 31.02 gm. of ingested N.

CASE VI.

Status præsens: Patient is emaciated and easily exhaustible, otherwise quite comfortable.

The average of the daily voided urine in this period was 1,617 c.c., with 2.8 per cent. or 45.27 gm. of urea. The fæces were examined four times within this time, and their solid residue averaged 48 gm. for twenty-four hours, with 4.2 per cent. or 2.01 gm. of urea. The average of urea excreted by urine and fæces *per diem* was therefore 47.28 gm., containing 22.09 gm. of N. In other words, there was 8.93 gm. of N. less on the average excreted *per diem* by these channels than had been introduced by the nutriment.

From May 12, 1896, to May 18, 1896, the patient lived on non-nitrogenous food. The average of the daily secretion of urine was then 1,608 c.c., with 2.5 per cent. or 40.2 gm. of urea. The fæces were examined for urea thrice in this period, and weighed when completely dehydrated 89 gm. daily on the average. They contained in the mean 4.9 per cent. or 4.4 gm. of urea. Together, therefore, 44.6 gm. of urea was daily eliminated on the average at this time, representing 20.8 gm. of N.

Case III.—From the date diabetic deterioration was first recognized until October 15, 1896, the patient was under strictly albuminous diet. The consumption of proteid food averaged daily about 180 gm., which represents 28.08 gm. of N.

During that time the average daily secretion of urine amounted to 4,055 c.c., with 2.9 per cent. or 117.59 gm. of urea. The solid residue of the fæces was 38 gm., with 7.3 per cent. or 2.77 gm. of urea. The

[1] This definition naturally presupposes the usual food supply.

120.36 gm. of urea thus excreted represented 56.24 gm. of N. Consequently 28.16 gm. of N less was ingested than excreted.

From October 17, 1896, to November 6, 1896, the patient lived on a mixed diet, that is, about 120 gm. of albumin, representing 1,872 gm. of N, was ingested *per diem.*

The urine on the average was excreted to the amount of 2,800 c.c. in twenty-four hours, containing 3.6 per cent. or 100.8 gm. of urea.

The solid residue of the fæces on November 6th amounted to 41 gm., and contained 5.5 per cent. or 2.3 gm. of urea. Taking this as the average, 103.1 gm. of urea was excreted daily. Thus 48.18 gm. of N left the body by urine and fæces, while only 18.72 gm. of N had been introduced by nutriment, leaving therefore a N deficit in the sytem of 29.46 gm.

From November 20 to December 28, 1896, on account of an albuminuria which had since developed, carbohydrates were prevailing in the patient's food. The amount of albuminates and albuminoids in the nutriment averaged about 70 gm. daily, and contained 10.92 gm. of N.

The quantity of urine voided during that epoch was on the daily average 1,817 c.c., and contained in the mean 3.4 per cent. or 61.78 gm. of urea. The residual fæces on December 11th amounted to 72.5 gm., and contained 1.5 per cent. or 1.09 gm. of urea. Together on the average, 62.87 gm. of urea, holding 29.45 gm. of N, was daily excreted. This means a daily N deficit of 18.53 gm. for this period.

Case IV.—From December 16, 1896, to December 19, 1896, the patient was under an exclusive albuminous diet, 180 gm. of albumin in milk, eggs, and meat being about the daily average. Thus the ingested N amounted to 28.08 gm. *per diem.*

The urine voided during these four days averaged 5,830 c.c. daily, and contained 7.6 per cent. or 443.8 gm. of carbamide. This means the excretion of 207.05 gm. of N, or of 178.97 gm. more than was taken with the food.

On December 20, 1896, I kept the patient fasting. This was done for therapeutic purposes, according to Naunyn's and von Mering's suggestions. The urine voided for the whole twenty-four hours (the fasting did not quite last all that time) amounted to 2,120 c.c., with 8 per cent. or 169.6 gm. of urea. This represents 79.25 gm. of excreted N, while practically there was none ingested.

From December 28 to December 31, 1896, I had the patient under food of a pronounced carbohydrate nature. The proteids which were thus ingested amounted to about 50 gm. daily, and contained 7.8 gm. of N.

The urine passed during this period averaged 4,590 gm. daily, with 8.2 per cent. or 376.38 gm. of urea. The fæces, which I examined for glucose and carbamide on December 31st, weighed when completely dehydrated 84 gm., and held 3.5 per cent. or 2.94 gm. of urea. The total amount of urea therefore averaged 379.32 gm. daily, and 177.26 gm. of N was therein contained. Consequently 169.46 gm. of N more was excreted than ingested at an average daily for this period.

From January 3 to January 5, 1897, the patient was again under an albuminous diet, and consumed about 190 gm. of proteid material daily, which contained 29.6 gm. of N.

The quantity of urine voided amounted in the mean to 5,100 c.c., and held 7.8 per cent. or 397.8 gm. of urea. The latter represents 185.9 gm. of excreted N, 156.3 gm. more than was introduced with the nourishment.

Case V.—Until February 25, 1897, the patient was under a totally albuminous diet, that is, about 180 gm. of different albuminates and albuminoids was daily ingested; 180 gm. of albumin represents 28. 08 gm. of N.

The daily average of urine passed amounted to 1,708 c.c., with 2.8 per cent. or 47.82 gm. of urea. The fæces when examined on February 22d weighed 63.5 gm. in their dry state, and contained just 5 per cent. or 3.77 gm. of urea. Taking the latter as an average, the total daily excretion of urea amounted to 51.59 gm., representing 24.11 gm. of N. This indicates that 3.97 gm. of N more was ingested than was eliminated by the kidneys and bowels.

From February 26 to March 4, 1897, for a period of one week, the patient lived upon non-nitrogenous nutriment. (I would like to add that the patient, a highly intelligent and educated gentleman, readily consented to take an absolutely carbohydrate nourishment with the least possible quantity of hydrocarbons, if it were for diagnostic and experimental purposes.)

The urine voided during the twenty-four hours averaged 1,793 c.c., and contained 2.9 per cent. or 52 gm. of urea.

The fæces, when analyzed on March 2d, in their residual condition, amounted to 97 gm., and contained 4.07 per cent. or 4.57 gm. of urea. Taking the latter as an average of the quantity of the stools, we have 56.57 gm. of daily urea elimination; that is, 26.44 gm. of N. From March 5 to April 16, 1897, and thereafter, the patient was under an albuminous diet again, ingesting about 180 gm. of albumin or 28.08 gm. of N.

The daily average amount of urine was 1,805 c.c., with 2.8 per cent. or 50.54 gm. of urea. The dried fæces on March 11th weighed 78.5 gm., and contained 6.9 per cent. or 5.42 gm. of urea. Taking the latter again as the average quantity of the stools, we have a daily average excretion of 55.96 gm. of urea, or of 26.15 gm. of N, 1.93 gm. less than was ingested.

Case VI.—Until August 4, 1897, the patient was under a mixed diet which contained about 50 gm. of albumin daily. This amount of albumin represents 7.8 gm. of N.

The urine during this period was excreted to the average amount of 1,970 c.c. daily, with 3.4 per cent. or 67 gm. of urea, which latter contains 31.31 gm. of N—this means a N deficit of 23.51 gm. On August 6, 1897, the patient took as nutriment five litres of cow's milk, containing about 215 gm. of casein and albuminates. This proteid matter represents 33.54 gm. of N.

The quantity of urine on that day was 2,600 c.c., and 3.5 per cent. or 91 gm. of urea was held therein. The solid residual fæces amounted to 42.5 gm., and contained 4.6 per cent. or 1.96 gm. of urea. Together 92.96 gm. of urea, or 43.44 gm. of N, was excreted that day; that is, 9.90 gm. of N more was eliminated than was introduced by nourishment.

From August 21st to the end of that month, carbohydrates and hydrocarbons served as nutriment of the patient. The approximate amount of vegetable albumin contained in the food I figured at 20 gm. daily; that is, 3.1 gm. of N.

The average amount of urine voided *per diem* was 1,730 c.c., with 2.2 per cent. or 38.1 gm. of urea. The residual fæces of August 22d and 26th, amounting in the mean to 94 gm., contained 3.3 per cent. or 3.1 gm. of urea; therefore the daily average of excreted urea amounted to 41.2 gm. of urea or 19.25 gm. of N. Thus we had here an excess of 16.15 gm. of N over the amount of N ingested.

A study of the cited cases will demonstrate:

1. That diabetic glycosuria *per se* is not directly dependent upon alimentation.

2. That the ingested carbohydrates do not influence the diabetic condition—to that extent—as generally supposed.

3. That diabetic azoturia is a distinctive phenomenon during the glycosuric stage of diabetic deterioration.

4. That diabetic azoturia is not a direct result of hyperingestion of albuminous materials.

5. That the amount of nitrogen excreted during the second stage of diabetic deterioration nearly always exceeds that of the nitrogen introduced with the nutriment.

Von Noorden,[1] the latest exponent of diabetes mellitus, alluding to his own observations as well as to those of Lusk, F. Voit, Hirschfeld, and Weintraut, still maintains that the waste of nitrogen is the greater the more the food value is depreciated by glycosuria, that this waste is very large as long as the diabetic is allowed to ingest the carbohydrates which are useless to him, and that it diminishes or discontinues when the nourishment consists to the greater part of proteids and fats.

"I am strongly inclined," says von Noorden, "to define the disease as follows: By the term diabetes mellitus is understood a disease in which the capacity of the organism for burning up grape sugar is morbidly depressed. We shall, indeed, see that all the phenomena of diabetes may, without compulsion, be explained by this formula, yet I hesitate to place the definition at the head of this treatise, for the reason that we have as yet no certain evidence that it exhaustively explains the condition actually present."

Von Noorden considers diabetes mellitus still as a disease *per se*, and caused by a disturbed chemismus, particularly of the glycolytic power of the organism, and, though this observer differentiates minutely between glycosuria and diabetes proper, he has not as yet recognized the diabetic deterioration.

IV. Deductions.—Albuminous substances are of a highly complex structure, and the position of their molecules is easily disturbed. Even the slightest influence may cause an alteration in the latters' position, and thus plasmatic bodies are readily changeable or decomposed. There are numerous and varying phases in the process of decomposition of albumin. Some phases will recur often and are deemed normal; others will not recur regularly, and we may consider such phases abnormal.

There is no doubt that the decomposition of albumin under certain conditions will give rise to the formation of dextrose. In glycogen-free animals there will occur a new production of glycogen, if they are subjected even to none but nitrogenous food. Some of the C-H-O molecules of albumin may combine themselves to form a carbohydrate body[2] or a series of similar compounds before their final and ultimate conversion in CO_2 and H_2O, in which form they leave the organism. The N molecule of the decomposing albumin will remain attached to some of the original C-H-O atoms, and may give rise to the simultaneous or alternate formation of a variety of non-colloid nitrogenous substances, as, for instance, amido-caproic acid (leucin), $C_9H_{10}(NH_2)O.OH$; tyrosin, $C_9H_{11}NO_3$; carbamide, $CO(NH_2)_2$, and many others. The ultimate disposal of the N molecule occurs in the form of ammonia. It is, moreover, not improbable that a part of the N molecule of albumin, without undergoing the different processes of transformation, is at once converted into ammonia.

If the formation of a glucose-resembling carbohydrate from the ingested proteids is a definite fact, then I see no reason why the protoplasm of the living organism—under appropriate conditions—should not also be dextrose-generic.

It may be assumed that the molecules of the tissue proteids—when subjected to certain influences—are capable of altering their respective positions in a similar manner as do those of ingested albumins. That is, plasmolysis of the living tissues may occur, normally or abnormally, under the formation of a glucose-like substance. The generation of dextrose by the living protoplasm is not necessarily followed by the latter's spontaneous and complete dissolution. It may regenerate if its production of glucose is a normal process, or it may persist for some time—minus the molecules of the generated carbohydrate—if the process is an abnormal one. In the latter instance, however, there is then no protoplasm as such any more, and it is only a question of time until its ultimate destruction.[1]

The healthy organism by plasmolysis may generate a dextrose-resembling carbohydrate normally, which in turn may undergo a series of conversions until its ultimate disposal as CO_2. One of these intermediate steps may be the formation of glycogen. In the diabetic condition the production of this amylaceous substance from dextrose may be decreased or totally suspended. The direct consequence of this would be diminished or no formation of fat, emaciation, and, if the dextrose has not undergone other alterations, hyperglykæmia and appearance of the glucose in the excretions. The accompanying azoturia may be accounted for by an increased plasmolysis.

The generation of dextrose by plasmolysis is, however, in all probability an abnormal process. In that case the plasmolysis is a catabolic process whereby the plasmatic substance cannot regenerate, and becomes disintegrated. This dissimilation of the living protoplasm occurs more in the character of a deterioration; that is, the protoplasm to all appearances may continue to exist, although it has lost its molecular integrity.

This plasmolytic dextrose-generic process I designate as diabetic deterioration.

In other words, diabetic deterioration is a more or less limited molecular disintegration of plasmatic tissue substance into a glucose-like body and a non-colloid nitrogenous compound.

Diabetic deterioration is always a systemic and general affection. The transitory form of so-called diabetes, the glycosurias of diverse origin—even experimental pancreatic diabetes—is in the first instance always the result of local disturbances. It is true, the causative factor of the deterioration may exert its influence upon the organism through only one channel, but it will not affect one organ more than another, and all the protoplasm will lose its molecular integrity.

I classify among diabetic deterioration, irrespectively of the percentage of dextrose present, all those chronic cases of glycosuria in which the excretion of the urea, the carrier of part of the N molecules of the tissues, continues to be permanently in excess; that is, when the amount of excreted N constantly, during a certain period, exceeds the quantity of that which has been ingested with the nourishment.

In order, therefore, to recognize diabetic deteriora-

[1] "Die Zuckerkrankheit und ihre Behandlung." Berlin, 1895; translation of the same as "Diabetes Mellitus," "Twentieth Century Practice," vol. ii., New York, 1895.

[2] Minkowski ("Untersuchungen über den Diabetes mellitus," Leipsic, 1893) maintains that a hundred grams of albumin split up in the body produce at least forty-five grams of carbohydrates.

[1] Physiological chemistry is limited by natural boundaries. The innermost vital reactions and processes can only be anticipated but never positively ascertained. Interference with the organism for investigating-purposes causes spontaneous alteration of the tissue molecules, and that which we happen to examine scrutinously is a different thing from that which it was in the system. Thus we know nothing definitely about plasmatic substances in a chemical respect. What we may examine is not the protoplasm any more; it has been protoplasm. As we do not know anything about the intrinsic changes in living protoplasm, it stands to reason that we cannot account for many diseases. This is particularly true of diabetes, in which, with exception of eventual secondary changes, nothing is perceivable, neither during life nor in necroscopies.

tion definitely, the patient ought to be kept under rigid observation for some time. His food should always be weighed and the percentage of its nutritive constituents approximately ascertained. This has to be done especially with its proteid matter. The excretions must be carefully measured or weighed, and the urine examined for glucose. Following this, an exact determination of the carbamide contained in urine and fæces should be undertaken and its contents of N calculated. Finally the amount of excreted N should be compared with that introduced by the food. There are very likely other substances besides glucose and urea, as the result of a dextrose-generic plasmolysis, to be met with in the excretions, but I have not made any observations in this respect as yet.

The later stages of development of an individual and the following decade, seem to me to be that period during which dextrose-generic plasmolysis mostly occurs. Thus diabetic deterioration may be described as an affection following individual development.

The underlying causes of the disintegration of protoplasm and its resulting production of glucose and carbamide seem to be a part of a probable inherent quality of the protoplasm, of a purely physico-chemical nature. Whatever they may be, this much I can say with certainty, that digestive disturbances are never the main factors of diabetic deterioration.

My arguments are to some extent based necessarily upon hypothesis. But is not hypothesis the instigator to scientific research? Has it not been the foundation for the establishment of many an invincible truth?

1238 Lexington Avenue.

IS NOT THE MORTALITY FROM SURGICAL DISEASE LARGER THAN NECESSARY?[1]

By CHARLES McBURNEY, M.D.,

New York

With anæsthesia, asepsis, and greatly enlarged and improved operative surgery, the immediate danger to life from surgical interference has very greatly diminished, so that increased confidence has become established in the minds of surgeons, physicians, and patients that few cases of surgical disease can reach such an advanced stage as entirely to preclude the possibility of relief by operation. And it is true that many conditions which formerly were necessarily fatal because they were considered to be beyond the reach of surgery are now safely operated upon, and more or less completely relieved.

Even partial success in these desperate cases is a very proper source of pride to the surgeon, and each one stimulates him to still greater effort to save those who are nearly moribund. The more desperate the condition and the greater the risk, the more intense his interest, provided the possibility of success by care and skill exists. This feeling is to a certain extent shared by the physician, who now, much more frequently than in former times, calls upon the surgeon for aid, even in very desperate conditions. In this way every surgeon becomes familiar with cases for which he can do little or nothing, because the disease has already gone too far.

During the last few years I have been especially struck with the rapidity with which many cases of surgical disease advance from a condition that is entirely curable to one that is entirely incurable, or from one that can be completely and radically treated to one that can be only partially relieved. Probably almost all surgical cases have their time limit, before which with proper treatment complete recovery can be assured, and after which, at least with our present resources, no efforts can be entirely successful. Exactly what this time limit is in each individual case we do not accurately know, but that there is such a limitation which is well worth our constant thought and study I am firmly convinced. Take, for instance, a case of strangulated hernia. Is there not undoubtedly a moment up to which the possibility, after relief of the strangulation, of a return of circulation in the involved gut still exists, and a moment immediately following when such complete re-establishment of the blood current becomes impossible? Or, in a case of progressive septic peritonitis, is there not a sharp limit to the time within which the removal of the primary source of the sepsis and of its local products is capable of putting an end to the disease? And does not after this limit immediately begin a period when such a condition of general sepsis is established as entirely precludes the possibility of recovery? Or in a case of carcinoma of the breast is there not a brief period during which the disease is absolutely local and so open to radical cure, and immediately after this a period when invasion of lymphatic vessels renders operative work only palliative? As further instances I would enumerate carcinomata and sarcomata in many different parts of the body, cases of bowel obstruction due to whatever cause, all wound infections, and especially suppurative diseases involving or threatening to involve the peritoneum. All of these diseases, with certain rare exceptions, when old age or complications of various kinds render surgical treatment inadmissible, are at the proper time susceptible of complete and radical cure. In other words, there actually is a time limit before which death can be averted, and after which death is, immediately or remotely, inevitable.

The question that I would raise is: Do we to-day, with all our eagerness to improve the results of our surgical work, devote nearly enough attention to the limit of time when perfect surgery is possible?

Even leaving out the question of life and death, what shall we say in regard to the extension of disease from one tissue to another, calling at a late period for a much more extensive or mutilating operation than would have been required but a very short time before?

What an enormous difference between a case of strangulated hernia operated on at a time when a complete operation can be done and the hernia radically cured, and a case operated on at a later stage, when gangrene of the gut has occurred, calling for resection of the intestine, followed by intestinal anastomosis or a permanent artificial anus! Compare two cases of appendicitis, one operated on in the period of quiescence after the first attack, and the other operated on during the second attack, when suppurative peritonitis renders a wide-open wound necessary and a large bulging hernia naturally follows. Besides these more marked instances, many others could be given in which the transition from simplicity to complication is less clearly defined. To-day a diseased joint may be safely treated by resection; in a week amputation will be necessary to save life. In the case that I presented to-night, there was a prolonged period when simple extirpation of the tonsil would have been sufficient. When the patient came under my care, the disease had extended so far on to the lower jaw that it was necessary to sacrifice the whole of the ramus. The probability of inoperable recurrence of disease in this case is much greater than it would have been had the operation been done two or three months earlier.

It is clear, of course, that the mortality from surgical disease would be very much diminished if all cases could be subjected to treatment before the time limiting the possibility of perfect cure had been passed. The responsibility for not allowing this limit to be

[1] Paper read before the Practitioners' Society on Friday, November 5, 1897.

passed is then very great, and deserves the fullest appreciation. That in many cases the limit cannot at present be accurately defined is undoubtedly true, and that it will even be thoroughly understood in all cases is not probable. It is easy enough, however, to appreciate the initial stages of many surgical diseases, and knowledge of their natural history should enable a moderately careful professional observer roughly to anticipate the limit before which treatment may be safe and perfect. A natural comment on these observations might be made, that they are trite enough, and that every one knows that, as a rule, the earlier in any surgical disease proper treatment is begun, the more secure will be a completely favorable result.

The point that I wish especially to make is that the sense of responsibility in selecting the time for surgical interference is in many instances not sufficiently acute, and that delay, in some cases of a few hours, in others of days, and in others of weeks, actually directly leads to partial or complete failure, or even to death itself. It is not always easy to decide upon whom this important responsibility rests. Sometimes the surgeon himself is at fault; sometimes, and not infrequently, the responsibility for fatal delay belongs to the medical practitioner who first has charge of the patient; sometimes the division of responsibility among too many persons leads to the unfortunate result; and often enough no one is to blame but the timid patient and his ill-advising friends. I cannot but believe that many of the obstacles to complete surgical success could be removed, and the mortality from surgical disease largely reduced, if the grave importance of selecting the early stages of disease for surgical interference was more clearly realized. Failure to select the most favorable opportunity for surgical interference is responsible for a very large part of the mortality following surgical disease.

MIDWIFERY AND MIDWIFE.[1]

By C. A. VON RAMDOHR, M.D.,

PROFESSOR OF OBSTETRICS, NEW YORK POST-GRADUATE MEDICAL SCHOOL; GYNÆCOLOGIST TO ST. MARK'S HOSPITAL AND GERMAN POLIKLINIK; MEMBER OF THE NEW YORK STATE MEDICAL SOCIETY, NEW YORK COUNTY MEDICAL SOCIETY, ETC.

MR. PRESIDENT AND GENTLEMEN: The subject of my paper, *i.e*, the undesirability of having midwives in New York State under such conditions as at present exist, has lately been brought home to me so forcibly again and again, and has recently been touched upon so frequently in medical societies that I have ventured once more to try to interest your honorable society in the highest therapeutics for this malady, viz., prevention of the disease.

A confinement, as we are all supposed to know, is a perfectly physiological procedure which nature ordinarily can and will take care of. An Indian woman on the march will give birth to a child, wash in the river, and be able to catch up with the tribe, which has left her behind alone to attend to her function. The Esquimaux, when a woman gets in labor, give her provisions for three days and close the door of the ice-built cabin with a big slab of ice. If after three days the wail of an infant is heard, the happy mother and child are liberated. If not, the door is not opened again. We civilized people, however, have become so accustomed to assistance being given our women when child bearing, that our newspapers report a case in which such an event has taken place without attendance, be that on the street or in some public conveyance; and yet they forget to report that usually no bad consequences result to mother or offspring.

[1] Read before the Society of Medical Jurisprudence at its one hundred and twenty-ninth regular meeting, November 8, 1897, at 17 West Forty-third Street.

The dangers of child bearing with us lie in infection firstly, and meddlesomeness secondly. It has been proved time and time again that if the conscientious accoucheur holds it his duty to be simply to see that no complications are present, or likely to arise, and simply to watch nature, he will be much preferable to some charlatan who pretends to an overcredulous public that he can supersede her. That each and every person who comes in contact with the patient is perfectly clean and does not introduce infection, sepsis, blood poisoning—call it what you will—ought to be perfectly understood, but unhappily cases which we know can and ought to be prevented prove that even the medical profession is sometimes too lax in disciplining itself in such a vital matter. Sepsis is practically an unknown disease in lying-in institutions at the present time, but examine the records of death among the poorer classes, just such as are attended primarily by midwives, and you will find them appalling, even while complacent medical men occasionally seem not to be able to write the word sepsis on their death certificates.

Now, let us see why we have to deal with midwives at all. From ancient times on, some women have preferred, and during some periods have been obliged to rely upon the ministrations of their own sex during this critical time. Women like Mme. Siegmund and Mme. Lachapelle have left their mark in the history of obstetrics and given lustre to the highly respectable calling of a midwife in the best sense of the word.

In continental countries such a calling is an essential factor in districts where distance or paucity of medical men make it impossible for them to officiate in all cases. In our country, and especially in our large cities, and again chiefly in this cosmopolis, New York, this institution has remained as a relic of the past, a bond of former home life; or the employment of midwives is propagated on account of financial reasons, for —and now comes one of the sources of dangers to the community—the midwife does not only for a paltry sum minister to the woman during her confinement, but comes for nine more days to wash and clean mother and child and attend to any other household duties which her good nature or her business interest seem to make commendable. That this woman in the best of cases can hardly keep her person and clothes in perfect sanitary order under such circumstances can be understood; that occasion frequently arises when medical advice is asked during those nine days, ay! and later, too, and given with a right good will is no secret. That women apply for fœticide most frequently to those persons who have confined them is a fact.

Let us now see from what material in the older countries midwives are selected and how they are drilled. For all practical purposes their training and duties are the same in all European States. A married woman wants to eke out the scanty wages of her husband, or a widow applies with a certificate of good character to the county physician, with whom she is probably acquainted, and after a good deal of red tape is admitted into one of those lying-in asylums which the government maintains for the delivery of poor women and the training of midwives. Here for six months or a year she is taught, not how to perform obstetrical operations, but first to wash and brush her hands, to keep herself tidy, to be subject always to the orders of a physician, never to prescribe, never to interfere, but to call assistance in such given cases as need be. Now at the same time she is taught in a popular way, theoretically as well as practically, the physiology of labor and her own duties to mother and child during that time, and what she has to do to the reconvalescent woman. She is always under the supervision of people trained to teach just such novices. She is never left unwatched; time and time again her hands are

examined as to their absolute cleanliness; again and again it is dinned into her ears that she can prevent disease, if she be only clean. After a six-months' or a year's sojourn in the institute, if she has passed an examination held by a different board, she swears an oath to attend her duties as prescribed, and may commence to practise. But during all her lifetime she is still under supervision. At certain times her carefully prescribed armamentarium is inspected. In cases of neglect she is quickly prosecuted. If cases of fever occur in her practice with any frequency, or cases are not reported properly, or, in fact, any of the numerous commands laid upon her in the interest of the community are violated, she has her license taken away a great deal faster than she has received it.

It will interest you to illustrate the minuteness with which the State tries to protect its mothers in Austria. For example, to give you a few samples from a criticism by Dr. I. Fischer of the "New Regulations for Midwives," published in the *Wiener medizinische Presse*, October 3, 1897: "It is the chief merit of the rules that midwives are reminded not to make too frequent vaginal examinations." Criticism: "Why are they not told that one or two are sufficient?"

"Washing and scrubbing of hands and forearms must last three minutes, then thorough cleaning of nails is in order, followed by a three-minutes' disinfection in carbolic-acid solution, as mentioned in the older rules, or in a two-per-cent. lysol or a one-per-cent. cresol solution." Criticism: "Why is it not ordered that these three minutes are to be controlled by a clock, or why is not the midwife ordered to have an hourglass with her, as she is in Germany?"

"We are glad that a midwife dares not practise while she is nursing an infected patient, until she brings a certificate from the attending physician that she is not likely to infect the new patient." Criticism: "But why is she not recommended, whenever possible, not to nurse such patient? . . . We also miss an order of non-attendance when her fingers are not in sound condition, as from a felon, a runaround, etc. . . . We admire the paragraph on ordering the temperature to be taken daily, and their being obliged to call in a physician whenever it surpasses 38° C. (100.4° F.). Lastly we are heartily in favor of the yearly control and post-graduate examination which has been ordered."

Now let us consider how New York treats her women citizens. The State as such does not take cognizance of midwives at all in its general laws, but only through special acts, and this only in very recent years.

Besides two or three similar acts, which I think include the cities of Syracuse and Buffalo, the most recent one became a law May 31, 1895, and, contained in chapter 842, laws of the State of New York of 1895, is called "An act regulating and restraining the practice of midwifery in the city of Rochester by others than legally authorized physicians."

Section 1 empowers the mayor to establish a board for the examination, licensing, and registering of midwives, consisting of three members, two of whom shall be physicians of at least five years' practice, and the third to be the health officer *ex officio;* to give them a compensation of $10 a day for time of sittings; and makes the duration of office three years.

Section 2 treats of organization.

Section 3 orders the board to hold at least one meeting each half-year, to charge $10 for each examination and certificate, which is to be recorded, and gives the money thus collected to the city treasury.

Section 4 treats of the limitations as to the power of midwives, forbids obstetrical operations, the administration of poisonous drugs, and treatment of disease except in emergency cases, and then orders a speedy call for a physician.

Section 5 gives the mayor the power to revoke certificate and license on recommendation of the board, which has first to have granted a hearing to the accused woman.

Section 6 makes the crime of a person practising contrary to this law a misdemeanor punishable by a fine of not less than $50 and not more than $100.

New York City has not even such special laws. Here any woman who brings a certificate signed by two registered physicans, to the effect that she is of moral character and therefore probably capable of ministering to a woman during childbirth, is thereby *eo ipso* a midwife, is permitted to register, and her certificates of birth or stillbirth are accepted by the board of health. Whether her training has lasted two days or two years, whether she has retained or ever possessed the first essential of a successful midwife—that is, keeping her person tidy and having her hands at the time in such an aseptic state as to vie with those of a surgeon about to perform a laparotomy—are ignored. Whether she owns her kit of proper or improper instruments is not examined into. No supervision after registration is at present possible or attempted, for whenever one of her patients falls sick, usually through her incompetency, some one, or one of these two licensed practitioners, is available to be called in, and the woman's death certificate is made out according to law, or the patient may recover.

Attempts at a change, which we all, I am sure, will admit, is desirable, have been made, but without success so far.

Midwives themselves will not help us, for reasons best known to themselves. American-born women do not take kindly to a calling which has no standing, while professional nursing gives them a much more honorable and lucrative position in life. There remain those foreign women who have had European training, most of which they have forgotten or misapply, or those graduated from so-called or miscalled American schools of midwifery. These institutes are private affairs, which mostly by advertising promise to make accomplished midwives out of workingwomen, in a given time for a given fee. The same promoters graduate their own pupils for an extra compensation. How much or how little each individual school teaches is indifferent. The system is just as bad as that of our former diploma mills used to be in this State. It is just as hard to have acts establishing separate licensing boards as it was to establish State examinations for physicians. Underground influence is being used, and the old-time cry is raised: "What! a larger fee for a confinement to a poor man in the interest of the money-grabbing rich physician?" The issue is lost in this demagogic logic and the bill slumbers in committee, while hundreds and thousands of wives are killed annually whose lives might be preserved to their families and the community if the legislators could be shaken up from their lethargy.

For one society alone, were it as strong as our own, to undertake this work, would be the work of Sisyphus, but the times are ripe for medical legislation, or I am much mistaken. We have among our prominent members, besides others, the distinguished president and vice-president of the New York County Medical Society, which makes it a special duty to promote public health and license practitioners. There will soon be a meeting of the State Medical Society in Albany, at which our honorable president will play a conspicuous rôle. Under such circumstances, gentlemen, could we not hope for success in securing adequate legislation properly to regulate the practice of midwifery by midwives in our Empire State?

45 Irving Place.

THE OPERATIVE SIDE OF ORTHOPÆDIC SURGERY.[1]

BY NEWTON M. SHAFFER, M.D.,

SURGEON-IN-CHIEF OF THE NEW YORK ORTHOPÆDIC DISPENSARY AND HOSPITAL.

THE founders of the New York Orthopædic Dispensary and Hospital builded better than they knew when, thirty-one years ago, they met and organized the work which calls us together on this occasion.

Thirty-one years ago orthopædic surgery was scarcely more than a name in New York City. It may almost be said that few outside of the medical profession and the technically educated classes grasped the full meaning of the word "orthopædic." A few surgeons, inspired largely by the late Dr. Henry G. Davis, were devoting themselves to the treatment of deformities, especially those occasioned by diseases of the spine and hip-joint. Modern orthopædic surgery was in its infancy, and the work of these pioneers was attracting the attention of the lay as well as the professional public. It was during this embryonic period that the founders of your institution applied to the State legislature for a charter, in the following language: "The purposes of the said corporation shall be to establish and maintain an institution for the treatment of physical deformities and to give instruction in such treatment—and more especially to afford surgical and mechanical treatment to the disabled and deformed among the poor."

It was the mechanical genius of Davis which contributed greatly to this new era in the treatment of physical deformities. It was he and his colleagues who made American orthopædic surgery famous. It was, however, the mechanical rather than the surgical side of orthopædy of those days which brought to the front the names of those who are to-day recognized as the fathers of orthopædy in this country, and it was the mechanical treatment of hip-joint disease and spinal disease, as taught by Taylor, which led to the foundation of your institution and which has had more or less effect upon the development of American orthopædic surgery. It was under these circumstances that your special charter was obtained from the New York State legislature. It would have been a matter of no surprise to me, knowing as I do the sentiment of the profession in those early days, and appreciating also the influences which originated our great work, if the charter had simply designated the mechanical treatment of deformity as the sole object of the corporation. But, with a wise and almost prophetic foresight, the charter was framed in a broad and liberal sense, and the portion quoted above might almost be called a definition of modern orthopædic surgery.

On previous occasions I have called your attention to the relation of orthopædic surgery to general surgery—to the necessity of a thorough mechanical training as a preparation for orthopædic work, and to the future demands of orthopædic surgery from a mechanical standpoint. It would seem only proper on this occasion, therefore, that I should dwell somewhat upon the operative aspect of the treatment of deformities.

The treatment of chronic deformities would be emasculated if mechanical treatment was omitted. Indeed, under those circumstances, there would be only operative surgery left. On the other hand, if operative surgery was omitted, mechanico-therapy would still find an important place in surgical science and the major part of orthopædic work would still go on. To the legitimate orthopædic surgeon, therefore, operative work takes a secondary and minor position, just as the mechanical part takes by far the more important place; and in true orthopædic surgery operative work, *per se*, has no real status. In short, if orthopædic surgery is to maintain its position among the specialties in medicine, it must exist upon a mechanical foundation and its disciples must be experts in the use of apparatus. At the same time the orthopædic surgeon should be well prepared to operate upon those patients who require special mechanical treatment after operation. Hence it is that I maintain that the simple excision of joints is not within the field of orthopædic work, because the general surgeons and the general hospitals are fully equipped to do this work and are glad to receive and care for this class of cases, the after-treatment of which ordinarily requires no special orthopædic training. The same may be said in a general way of the operative treatment of knockknee and bowlegs. The artificial fracture of a bone requires the same treatment as an accidental fracture, and this certainly comes within the scope of general surgery. Under these circumstances there is no occasion to fill the wards of an orthopædic hospital with patients of this class, as long, at least, as there is such a great demand upon it for strictly orthopædic cases, which are not as a rule received by the general hospitals. For example, a patient with knee-joint disease or hip-joint disease needing excision, or a patient with rachitic leg deformity requiring osteotomy, applies for admission to your wards. Am I, as your surgeon-in-chief, justified in receiving the case when there are fifty or more cases of hip-joint disease, spinal disease, clubfoot, etc., which urgently demand your care and which are awaiting admission to your wards? My reply is, "No." We could fill our wards with operative cases in a month, the larger number of which do not require orthopædic care after operation, and which can be cared for in every way in the general hospitals. I certainly feel it my duty to decline them, when the only objects I would have in admitting them would be to gratify a personal ambition to appear as an operative surgeon, and to submit for your consideration at the end of the year an ample table of "operations performed." Some surgeons best known as orthopædic surgeons are wasting their time on work that is well done by general surgeons and well performed in general hospitals. These men are making a serious error, I think, and are retarding the normal growth of true orthopædic surgery. Some day these facts will be appreciated. It may not be in my day, but sooner or later the truth will prevail, and both the medical profession and humanity will be benefited. In the mean time I shall keep on in the course I marked out twenty-four years ago, when at an early age in my professional career I had the opportunity to gratify my surgical ambition in the orthopædic wards of St. Luke's Hospital. Nor is that opportunity lacking now, with the great mass of clinical material which presents in the service of your institution. I am gratified to know that the seed sown nearly a quarter of a century ago is bearing good fruit.

The operative part of orthopædic surgery therefore becomes the simple but necessary adjunct of the mechanical work. One may be an operative surgeon and know but little or nothing of real orthopædic work, but the orthopædist must be the one and know the other. One may perform all the major operations of surgery, and yet not have the requisite technical knowledge properly to adjust a hip splint or a spinal brace. The orthopædic surgeon should be able, if the after-treatment demands it, to excise a joint or to perform any operation which supplements mechanico-therapy, but in all but very exceptional cases he should confine his cutting-work to that field which supplements his mechanical operations.

Nor does it follow, I think, because a deformity exists, that the patient should necessarily come under

[1] A portion of an address delivered before the trustees of the New York Orthopædic Dispensary and Hospital on the occasion of their thirtieth annual meeting, held November 15, 1897.

the care of the orthopædic surgeon, any more than that the general condition giving rise to the retinitis of Bright's disease, or to the tabetic atrophy of the optic nerve in locomotor ataxia, should come under the care of the ophthalmologist. All specialties have their origin in general medicine or general surgery. The existence of a specialty depends upon several factors, the important one being the necessity for the development upon certain lines of a neglected branch of medicine or surgery involving patient study and careful research. It is along these lines that a specialty succeeds, and the danger of specialism of the present day lies in the fact that those who follow it are prone to invade other fields. The fault with many of those who are known best as orthopædic surgeons is that they do not confine themselves to orthopædic work; they often operate when there is no necessity for cutting, and they are not familiar enough with the technique of mechanical work to get the best results from mechanico-therapy. They do the work of the general surgeon instead, neglecting or ignoring the plain path of duty which lies so patent before them.

Why is this so? A few extracts from a recent editorial in the New York MEDICAL RECORD, may help us in answering this question. The editorial referred to is entitled, "Is Gynæcology Destined to Become an Obsolete Specialty?"[1] After a general consideration of the relation of gynæcology to general surgery, the writer says: "Not content with confining themselves to their proper region, they [the gynæcologists] have reasoned that their familiarity with abdominal surgery should render them the equals if not the superiors of general surgeons in the handling of cases which bear no relation to diseases of the pelvic organs." The writer then asks: "How is it that this change has come about in America, when abroad the distinction between the gynæcologist and general surgeon is just as sharp as ever? It appears to be due to some extent to the fact that the commercial factor has become prominent to the exclusion of the scientific." Again: "If gynæcology is to remain a specialty, it must be because its followers continue to demonstrate the fact that they can do the work better than the general surgeon. . . . It is along the line of conservatism that the battle must be fought, not radicalism." Still further: "Gynæcology is the natural outgrowth of general surgery, but the contrary is far from being true, and any attempt to reverse the condition must end in ultimate failure." And finally: "Let gynæcologists prove that their specialty is capable of development along other lines besides those of radical surgery, and there is no danger that it will ever come to be regarded as unnecessary." Comment on these plain statements seems superfluous. But if the words "orthopædic surgeon" or "orthopædic surgery" be inserted in place of "gynæcologist" or "gynæcology," in the quotations given above, the truth will be apparent to the candid observer. It will be along the lines of conservatism that orthopædic surgery will be developed—not on the lines of operative surgery—and it will be all the better for the men now engaged in preparing for future work in orthopædic surgery if they bear these facts in mind.

[The remainder of the address was devoted to statistical facts and the work performed in the institution during the past year.—ED.]

To Abort a Bubo.—Pressure bandage, when suppuration is not too far advanced, by folds of cotton carefully adjusted and a cocoanut-sized wad of tightly compressed cotton placed over the whole and retained by a very tight spica, produced abortion of the process, in nine out of twelve suitable cases.—GAETHER.

New York MEDICAL RECORD, February 27, 1897.

Clinical Department.

ABSENCE OF PAIN AND THE VOLUNTARY MUSCLES AS AUXILIARY AIDS IN LABOR.

BY JOSEPH N. STUDY, M.D.,

CAMBRIDGE CITY, IND.

IT has been said that parturition is never absolutely painless in womankind, and that pain is so constantly present as to characterize it as one of the most prominent clinical phenomena of labor. Pain in labor is usually attributed to the contraction of the involuntary muscular fibres of the uterus encroaching upon the sensory nerves and filaments. The following case well illustrates the title of this subject.

On July 31st, at 11 P.M., I saw Mrs. W——, aged thirty-two, in her fourth pregnancy. I had attended her in all of her previous confinements. The first child I delivered with forceps. The second confinement was normal. She was delivered of twins at the third confinement. She stated that she believed herself pregnant about two hundred and eighty-six days, and with the exception of a slight vaginal discharge had no symptoms of immediate confinement. A vaginal examination revealed the cervix fully dilated, the vertex presenting in the first position. At the expiration of three hours no pain whatever was complained of. The fact that my patient resided nearly five miles from my home and I had an important engagement six hours later caused me to ask the woman to take her position in bed. I then requested her to seize my hands and to make great effort at pressing down, while I aided by pressure over the fundus of the uterus. This effort was repeated every four or five minutes for two hours, when a well-developed male child was born alive. Only when the head was passing over the perineum was pain complained of, and that was insignificant.

A CASE OF PNEUMONIA TREATED BY VENESECTION.

BY ALFRED Q. DONOVAN, M.D.,

ELIZABETH, N. J.

THE fashion of bleeding has become extinct in our practice of to-day, and he would be a bold surgeon who should endeavor to revive it. Yet I believe that it was occasionally beneficial, and I wish to report a case of my own in which I think venesection was of decided service. From the results of this case I am inclined to think that in cases of pneumonia, when the patient is in sthenic condition, it is invaluable.

My patient, aged seventeen years, five feet four inches in height, and weighing about one hundred and eighty pounds, by occupation a fruit dealer, was sent to the Alexian Brothers' Hospital, Elizabeth, N. J., April 13, 1897, suffering from a double pneumonia. On the fourth day after his admission his respirations had gradually diminished to 60, his temperature was 104° F., and his pulse 140. He seemed to be rapidly sinking, and the prognosis was very bad. The ordinary remedies had been used, such as strychnine and digitalis in combination with the supporting plan of treatment, together with inhalations of oxygen, but all seemed to be of no avail. At this period I thought of venesection; I opened the cephalic vein and allowed about ten ounces to escape. After a few hours the temperature fell to 102° F., the respirations to 35, and the pulse to 100, and the man expressed himself as breathing more easily. The blood was examined microscopically, and pneumococci were found. For two days the patient was apparently better. After this period his respirations again went to 50, with pulse and tempera-

ture increased; he was again relieved of ten ounces of blood, and again the respirations fell to 35, with a reduction of temperature and pulse. From this time he gradually improved, and was finally discharged cured, May 10, 1897.

FORCED ENEMATA IN THE TREATMENT OF INTUSSUSCEPTION.

By THOMAS H. HAWKINS M.D.,

[illegible]

A LITTLE child, about eight months old, was brought into St. Anthony's Hospital, by Dr. E. C. Hill, of this city, June 16, 1897. Dr. Hill had already diagnosed intussusception. I made a careful examination and confirmed his diagnosis. Dr. Leonard Freeman was asked to examine the child, and agreed with us as to the nature of the lesion. The child had been vomiting persistently for about twelve hours, with no action of the bowels. A distinct mass could be felt in the right side of the abdomen, two inches above and about two inches to the right of the umbilicus. We advised laparotomy. Before doing the operation, however, Dr. Freeman suggested that it might be a good plan to inject one-half pint or more of warm water, and if this came away tinged with blood there certainly could be no doubt as to the correctness of our diagnosis.

The suggestion of an enema called to my mind several cases of this kind under my care during my residence in New York City, in the years 1874–76. In the latter year I read a short paper, containing a report of three cases of intussusception treated by forced enemata, before the Eastern Dispensary Medical Society. This article was published in the *Medical and Surgical Reporter*, December, 1876. These cases were successfully treated, and there was never a return of the trouble, so far as I have been able to learn. Two of the patients were under my observation for some five years afterward.

I therefore concluded to try the injection method in the present case. The child was placed across the nurse's lap on its abdomen and its body allowed to hang head downward. The nozzle of a bulb syringe was inserted into the bowel and the buttocks were compressed tightly. The water was pumped in rather slowly at first, and was violently expelled; but gradually more force was used, and the water entered more easily. About one gallon was used in this way in from six to seven minutes. When the child had been placed in bed on its back the tumor was again felt for, but could not be found. Dr. Hill, Dr. Freeman, and myself made a careful examination and decided that the invagination had probably been overcome. The vomiting gradually ceased, but there was no passage of fæcal matter for nearly twenty-four hours, though there was considerable discharge of blood and mucus. The child made a perfect recovery.

In the article published in the *Medical and Surgical Reporter*, if I remember correctly, I laid considerable stress on the necessity of using a large amount of fluid with a great deal of force. I also took the ground that there is practically no danger of rupture of the intestine; that, in fact, in cases of acute intussusception the invaginated portion of the intestine, on which the greatest strain is exerted, is also the strongest part of the gut, by reason of the reduplication.

I am led more particularly to report this case because of an article published in the MEDICAL RECORD, July 17, 1897, by Dr. C. L. Gibson, of New York, entitled "Mortality and Treatment of Acute Intussusception." In this article the writer, in speaking of enemata, says that they are distinctly dangerous, and that the amount of pressure which can be used is very limited; that the quantity of water should not exceed one and one-half pints, and the pressure should not be greater than three feet. From this I infer that he uses the fountain syringe. The use of the fountain syringe will certainly not succeed nearly so well as the use of the bulb.

One other point in connection with this last case, namely, that water unquestionably found its way through and passed from the mouth of the child. I do not propose that forced enemata with fluids should be substituted for laparotomy in all instances. I merely call attention to this case and the report of my former cases, that they may be considered for what they are worth in the study and future treatment of intussusception.

ECLAMPSIA DUE TO PHIMOSIS IN A CHILD SEVEN MONTHS OLD.

By HERMAN BESSER, M.D.,

[illegible]

ON August 11th I was called to attend a male infant in convulsions. On arriving at the house the following history was obtained from the mother: The patient was a second child, aged seven months. A previous child had died at six months, of convulsions. The baby had never nursed; it was fed first on condensed milk, 1 to 12, for three months, and later a food of the proprietary type was substituted. This, also failing to agree with the child, was followed with cow's milk, diluted one-half with barley water, with better results. The child had appeared to be getting along fairly well up to a week previous to my visit, when the mother noticed that it became fretful, screaming at night as if in great pain. These attacks were thought to be colicky, as the infant would draw up its legs until its knees almost touched the abdomen. Catnip and fennel teas had been given, without relief.

After I had obtained the foregoing history, the child was stripped and laid upon the bed, when I noticed that all its muscles were relaxed, the child lying perfectly limp. Examining the head, I found it rather large, with parietal bosses decidedly prominent; fontanelle, 1½ x 1. The ribs were beaded, the epiphyses somewhat enlarged, and the child was pot-bellied. The child had passed three green, slimy, undigested stools during the previous twenty-four hours. It had had no fever, the mother believed, but the thermometer then registered 103° F. in the rectum. The respirations were slow and deep, and the pulse was rapid and feeble. The child was apparently in deep coma.

I concluded, for want of more positive signs, that the condition was due to an intense intestinal intoxication, and ordered a mustard pack. While this was in preparation I turned my attention to the child, and as my hands touched the abdomen it seemed unusually tense. The percussion note just above the umbilicus was tympanitic, while immediately below and on either side it was flat, with a decided sense of resistance to the finger. On questioning the mother as to the amount of urine passed, she replied that for the two days previous she thought the diaper had not required changing so often as before, but she had not attached much importance to this fact. I immediately made an examination of the penis, and found that the prepuce was exceedingly long and adherent. Taking a grooved director, I tried to insert it into the orifice of the prepuce and push aside the fold of mucous membrane, but it was with considerable difficulty that I succeeded in forcing back the prepuce far enough to catch a glimpse of the glans. The mucous membrane had become so adherent that the resulting obstruction to the orifice of the glans almost completely prevented the outflow of urine, which was thus dammed back into the bladder, dilating it to such an extent

that it occupied a large part of the abdominal cavity. I finally succeeded in breaking up the adhesions, when the pent-up urine was discharged, saturating the bed and the clothing of the physician. The child was then placed in the mustard pack, and within a few moments was restored to consciousness.

I left a grain of calomel to be given in divided doses, and a fourth-grain Dover's powder every two hours. The following day I found the patient looking bright and happy. He had slept well during the night and passed an abundance of a highly colored urine. He took food eagerly and appeared to be none the worse for the previous night's experience. I suggested to the parents that circumcision would remove any chance of a recurrence of the symptoms, and two days later at their request performed this operation, which was followed by an uneventful recovery. Under suitable diet the child is now doing well.

242 West One Hundred and Twenty-Third Street.

STRANGULATED UMBILICAL HERNIA.

By WILLIAM T. SMITH, M.D.,

Hanover, N. H.,

Surgeon to the Mary Hitchcock Memorial Hospital.

The report of a case of this nature by Dr. Coley, in in a recent issue of the Medical Record, moves me to tell of a case in my own experience, which illustrates a phase of country practice.

I was called to see the patient in consultation with Dr. G. W. Weymouth, of Lyme. She lived in a small, unpainted house, beautifully situated on the lower slope of a mountain. There were two rooms on the first floor—a kitchen and a bedroom. In the latter apartment lay the patient, a woman of some two hundred pounds' weight. Half a dozen children were scattered about, the youngest little more than a baby. The mother from her bed commanded a view of her domain and still directed its affairs. We found a spheroidal tumor, five inches in diameter, tense, tender, dull on percussion. It had been out about thirty-six hours; the bowels were obstructed, and there were nausea and pain. After repeating unsuccessfully attempts at reduction which had already been made, we prepared for operation. There was a stove in the kitchen, and there was wood. The teakettle had been worn out and its place was supplied by a dingy tin pail. For washing-purposes there was the tin basin in the sink, which served the whole family. Under the sink was a pail of refuse. Exploring the pantry for a clean "dripping-pan" in which to boil instruments, we found a utensil of that kind, but it retained so much of its last contents that we discarded it. Neighbors had meantime appeared, and we made requisition on them. We obtained in this way a kettle and pan and some bowls and pitchers. A messenger was dispatched to the store, one and one-half miles away, for towelling and a paper of pins, of which there was none in the house. In the course of time instruments were sterilized, bichloride solutions were made, the field of operation was prepared, and on the bed where we found her we attacked the tumor. An incision was made around it near its base, going through skin and subcutaneous tissue. Skin and subcutaneous tissue were then dissected back as far as the edge of the aponeurosis surrounding the neck of the sac. The sac being opened, gut and omentum were found in it. Some recent adhesions were broken, and the edge of the ring was nicked to permit the return of the gut, which was viable. A mass of congested and matted omentum was tied off with catgut and removed, and the whole sac with the skin on its upper part was amputated. The aponeurotic edges of the ring were drawn together with stitches of kangaroo tendon, which included the peritoneum. The superficial tissues were sewed with silkworm gut and antiseptic dressing was applied. The wound healed by first intention. The patient resumed her ordinary duties in a few weeks, and five months after the operation gave birth to a healthy child. There has been no return of the hernia.

Progress of Medical Science.

Successful Treatment of Circumscribed Traumatic Aneurism of the Right Internal Carotid Artery within the Cranium by Means of Ligature of the Common Carotid.—Hinde (*Journal of the American Medical Association*, December 4, 1897, p. 1,154) has reported the case of a Chinaman, thirty-six years old, who eighteen months before coming under observation had been felled to the sidewalk by a blow from the shoulder, striking the occiput in his fall. The man at once arose and walked home, a distance of a block, and lay down for about ten minutes. On the following day he felt well enough to resume his work. Some time afterward both eyes began to redden, the right one in greater degree, and in a short time it was noticed that the right eyeball commenced to bulge forward. The redness and the exophthalmos on the right side steadily increased until the patient came under observation, when the palpebral, conjunctival, subconjunctival, and anterior ciliary veins of the right eye were found to be greatly enlarged and tortuous. No pulsation could, however, be detected in any of these vessels, and none on light palpation with the fingertips applied to the eyeball. The motility of the globe was preserved, except that in attempts at abduction it halted at a point slightly beyond the mid-position. The reflexes of the right pupil were enfeebled. The ophthalmoscope disclosed enlargement and tortuosity of the retinal veins, but an absence of pulsation. The arteries were of normal size and course. Both arteries and veins, especially on the surface of the disc, were marked by white lines along their walls, indicative of perivasculitis. Disc, retina, and choroid were normal in appearance. The veins of the left eye were somewhat enlarged throughout, but presented otherwise nothing abnormal. The sensibility of the right cornea was less acute than that of the left. The visual fields were alike and normal. The acuity of vision was slightly greater on the left than on the right, but fairly good on both sides. On placing the cup of a stethoscope over the closed right eye, a loud blowing bruit or murmur was heard synchronous with the heart beat, and an intermittence of the heart's pulsation from six to eight times per minute was readily detected. The same conditions, in slighter degree, were present over the right temporal region, and in still slighter degree in the left temporal region. In all of these situations the aneurismal sound was greatly increased when the patient stooped forward. It disappeared completely on digital compression of the right common carotid artery in the neck. On further inquiry it was learned that the patient became conscious of a noise in the head some six or seven days after his fall, and that it had grown steadily louder. The conclusion was reached that an aneurism had formed on the internal carotid artery within the cranium, perhaps secondary to fracture of one of the bones at the base, at a point where the vessel passes on the side of the body of the sphenoid bone between the layers of the dura mater and in immediate proximity to the cavernous sinus; compressing the latter and preventing the return of the venous blood from the contents of the right orbit, but not affecting the arterial supply; compressing the trunk of the sixth nerve, and in slighter degree also the ophthalmic division of the fifth nerve.

To remove the possibility of syphiloma of the brain, large doses of potassium iodide were administered for six weeks, without improvement. Operation was therefore advised, and it having been agreed to, the right common carotid artery was occluded in the neck with two ligatures, one-half inch apart. The immediate result of the operation was a complete cessation of the bruit, with increase in the exophthalmos, which, however, subsequently receded. Under treatment with the faradic current the paresis of the right external rectus muscle and diplopia that had developed were greatly improved. The ultimate result was entirely satisfactory, the patient being freed from all his previous symptoms.

Impetigo and Ecthyma have been shown by Balzer and Griffon, in a bacteriologic study of thirty-one cases of the former and fourteen of the latter (*Le Bul. Méd.*, October 31st), to depend upon the constant presence of streptococci in the form of diplococci like fine grains, included in the protoplasm of the leucocytes or arranged outside of them. Cultivated in bouillon the microbe takes on the features of the classical streptococcus pyogenes. Inoculation experiments show that the organism is truly pathogenic (causing abscess, erysipelas, and even fatal septicæmia).

Obstruction of the Small Intestine by a Gall Stone.—Bradbury (*British Medical Journal*, September 25, 1897, p. 796) reports two cases of impaction of the small intestine by gall stones attended with symptoms of obstruction. The condition is a rare one, having been observed but once in the Manchester Royal Infirmary between the years 1883 and 1896 among fifty thousand in-patients, and only four times during twelve months in some of the largest hospitals of England, representing altogether eighty thousand in-patients and several hundred thousand out-patients. The first case occurred in a man, sixty years old, and was complicated by the existence of cystitis and a general debilitated condition that rendered diagnosis almost impossible. The second occurred in a woman, also sixty years old, in whom there were no symptoms until obstruction occurred. The one case terminated fatally, the other in recovery. In neither case was there a history of jaundice or colic, or of a similar previous attack. In the one case the stone was about one and one-half inches in diameter and nearly spherical. In the other it weighed nearly one-half ounce, was almost two inches long, a little more than one inch in diameter, and had a circumference of three inches. In the second case no indication whatever of any hepatic disturbance existed, and until symptoms of obstruction occurred the patient was quite well. In the first case, however, there were indigestion, tenderness and enlargement of the liver, rigor, and rise of temperature, with profuse sweating. Under chloroform a localized swelling was felt in the right hypochondrium, but this disappeared completely later. Neither hemorrhage nor tympanites was present in either case at any time. Post-mortem examination in the one case disclosed the presence of a gall stone impacted in the jejunum, it having escaped from the gall bladder into the first portion of the duodenum through an opening about one inch in diameter. In the second case the stone was passed after the injection of an enema. In both cases the vomit was copious and almost like pure bile, but toward the end it became slightly stercoraceous in the first. In neither was the pain of exceptionally severe character. In the fatal case the symptoms lasted ten days; in the other, two days.

Cant (*British Medical Journal*, October 30, 1897, p. 1,258) reports three additional cases of obstruction of the small intestine by a gall stone, occurring in a woman sixty-five years old, a man about forty-eight, and a woman about fifty, respectively. In the first abdominal section was performed and the calculus removed, but death ensued about a week after the operation. In the second also cœliotomy was performed and the stone removed, but death resulted shortly after the operation. Cœliotomy was likewise performed in the third case, in which recovery ensued. In two of the cases an attempt was made to break up the concretions with a needle, but without success. None of the patients had previously had symptoms of gall stones, but only bilious attacks; nor had they suffered from severe pain preceding the obstruction. The vomiting was at first of a markedly bilious character and gradually became stercoraceous.

Physiologic Mobility of the Liver.—Dr. Laborde has demonstrated (Société de Biologie) that the lower border of the liver undergoes changes of level much more extensive than has been thought to be the case. Examination by the radioscope during active respiration shows an elevation of as much as six centimetres at times. This is an important point to remember in percussion of the organ.

Purpura Due to the Vapors of Benzin.—Drs. Lenoir and Claude related an instance at the last meeting of the Société des Hôpitaux which would tend to show that benzin might be a causative agent in even fatal instances of purpura. A dyer, twenty-seven years of age, presented hemorrhagic pleurisy as well as purpuric blotches and bleeding from various mucous membranes, leading to extreme anæmia and death. Autopsy revealed numerous infarcts. The occupation in which the fumes of benzin were inhaled had been given up some months before death, but not until several months after the onset.

The Employment of Thyroid Feeding in the Treatment of Insanity.—Cross (*Edinburgh Medical Journal*, November, 1897, p. 471) reports a series of twenty cases of various forms of insanity, including excited melancholia, simple melancholia, enfeeblement, dementia, senile insanity, and chronic mania, in which thyroid feeding was employed as a therapeutic measure. All of the cases showed a greater or less reaction to thyroid administration, as shown by slight rise of temperature and slightly increased respiratory frequency, together with more marked changes in the pulse, which was not only increased in frequency but also distinctly weakened. In all cases the pulse was the first to show any change and was the condition most affected; and this reaction increased and became most pronounced toward the end of the treatment. After the treatment was discontinued, the reaction passed off in the majority of cases, although it was quite noticeable for at least a week. As regards the relation of the mental condition to the amount of reaction produced, no definite statement could be made. One of the cases that improved showed a slight reaction, while one that presented no change mentally reacted very strongly, although the amount of thyroid given was the same in each. None of the eight males treated became excited during treatment, while the only cases of permanent improvement occurred in male cases. On the other hand, seven of twelve females became excited or showed increased excitement during the treatment, although no permanent improvement occurred. Of the twenty cases treated, two showed permanent improvement and both of these had previously been regarded as hopeless on account of the stationary character of their mental condition. Although none of the other cases was so distinctly benefited, it appears to be indicated that thyroid treatment should receive a fair trial before any patient suffering from insanity is regarded as hopelessly incurable.

MEDICAL RECORD:

PUBLIC HEALTH IN RELATION TO THE MILK AND FOOD SUPPLY.

THE strides made toward perfecting a system of public hygiene is one of the features of the present age. The fact is being slowly but surely grasped by the community at large that many of the epidemic diseases which have from time immemorial been regarded with the utmost dread can not only be avoided, but can be absolutely stamped out. This happy result, however, can be attained only by the exercise of great vigilance on the part of the sanitary authorities backed by the co-operation of the people themselves. The boards of health have done much, but if they were convinced that the sentiments of the general public were wholly with them their powers for good would be immensely enhanced. Many of the regulations introduced by them are beyond the scope of the ordinary lay mind, and are looked upon as unnecessary and troublesome. Indeed a large number of the medical profession itself regard some of the present-day notions in respect to hygiene as savoring of faddism, and will require further and more convincing proof before accepting them as anything more than experimental. Nevertheless, on the more salient and important points there is a pleasing unanimity of opinion. The fact is recognized on all hands that an uncontaminated water supply, a pure and wholesome milk supply, an efficient sewerage system, a proper disposal of refuse, and cleanliness in the manufacture and handling of all articles of food, are essential to the well being of each and every individual. Of these, without doubt, the question of pure water is the most important, but the subject of late has been so fully discussed in all its bearings that it would be superfluous to do more than merely refer to it here. Next in importance comes milk, and this again is a matter which has been thoroughly well threshed out. Still it is satisfactory to note that the public and even the lower classes are beginning to understand the benefit of an untainted milk supply, and to appreciate the efforts of those laboring in their behalf to achieve this object. When retailers of milk, both wholesale and retail, become alive to the fact that the people demand a genuine article and will take no other, they will quickly realize the situation and will be careful to supply what is required. One method of adulterating milk, largely practised among dairymen, may be mentioned here—the addition of water is referred to. In the annual report of the commissioners of health of Milwaukee, attention is drawn to this custom in these words: "Analyses of milk made in this department have shown that lake water has been added to the milk as a diluent, and in other instances well water. In several cases of the latter kind it was shown that the well from which the water came was filthy and the water unfit for drinking-purposes, but it had been added to the milk, so that nearly one-third of the entire bulk was water."

The bakeries and candy manufactories of Milwaukee underwent early in the year a systematic examination by the department of health, and their condition was found to be such that legislation was brought into force to abolish the evils.

The custom of exposing fresh fruit, candies, fish, vegetables, and various other articles of food on the streets is very prevalent in many parts of America. This practice is greatly to be deprecated, as it is not only a source of danger, but also extremely disgusting. When one considers the dust and filth that is being continually wafted on the breeze in all towns, this fact will be brought home in all its nastiness. If, as suggested in the Milwaukee health report, the people would take the matter into their own hands and refuse to purchase any article of food exposed to such conditions, the practice would soon be brought to an end. This question should be well ventilated in the public press; the more it is aired, the sooner will the filthy habit be stopped.

OFFICE BORES.

IT is a general belief that the poor doctor is always overjoyed when a patient, no matter of what kind, enters his office to swell his coffers. The number of bores that constantly beset him and tap his energies through the exasperating conduits of long and uninteresting accounts of trivial ailments is never taken into account. Aside from his strain of self-control and the enervating influences of smiling dissimulation, there is a special harm to the victimized adviser's sympathies in the engendering of a retaliatory unconcern in the patient's present condition and an indifference to its final ending. If perchance there is a sudden and unexpected interruption of all the symptoms usually designated heart failure, there comes a feeling of complacency in his contemplation of the obituary notice of the sufferer, which promptly settles all old scores and places the lucky survivor on the high plane of becoming resignation to the decrees of a kindly fate. Time is the only thing that must tell in such a race with the inevitable.

In the mean while the tales of woe must go on. The uprisings and downsittings must be noted by urination at night and defecation in the morning. It is comforting for the innocent professional victim of such constant watchfulness to realize that at such times he is always kept in mind. The urinary bottle with its daily tribute is ever ready to offer its sugges-

tion as to what has been done and still must be done so long as the visits continue. Each receptacle marshals itself in the solemn waiting row of similar odorous companions ruthlessly consigned to dilatory neglect, and the effectual corking of its contents is an implied revenge on the ever-ready fluency of the generous distiller. All such patients mean well, and so does the consultant who naively declares, after emptying the bottle, that "nothing was found" in the specimen.

Then comes the furtive young man, with wavering focal concentration, weak lip, and pasty palm, whose manly substance is tapped in the unguarded hour of sleep, and who wakes only to find that all is gone. Even this may be tolerable in comparison with the livelier and more ambitious youth, who voluntarily courts the pang of repentance in his more progressive ventures in the highways and byways of forbidden pleasures. What is lacking in the effusive mucosity of one is more than made up in the other. The miserly mournfulness of the spermatorrhœic is duly offset by the generous prodigality of the gonorrhœic. On the principle of easy come and easy go, the virus is scattered in the office of the doctor, on his carpet, chair, paperweight, doorknob, and towel, with a zeal that is grimly suggestive of a better cause. The tear of pity, if it ever comes for the oozy sufferer, can never be safely wiped away by the hand that has shaken his.

And lastly, who does not see the young and confiding unmarried female, who has caught cold by temporarily sitting on picnic grass, and who tells the old, old story of a deferred catamenial hope that maketh more than one heart sick?

Or, worse than this, how often does the casual and plausible youth mock the claims of an ordinary credulity when he confidingly asks, on behalf of a dear and absent friend, for the pill that will do the business and end anxiety?

Think of the poor doctor who must be made to believe it all, and sympathizingly play the usual fool besides. "Next—come in, please."

DISPOSAL OF GARBAGE.

One of the most serious obstacles in the way of a more satisfactory system of public hygiene is the disposal of garbage. The question presents numerous difficulties and must be regarded from an economical as well as a sanitary standpoint. There appears to be some confusion as to the correct definition of the term garbage.

The committee appointed by the American Public Health Association define the word as follows: "By the term garbage is meant animal and vegetable waste matter subject to rapid decay, from kitchen, markets, slaughter houses, etc., but not including nightsoil and street sweepings." The methods now in use for the disposal of garbage are one and all in a greater or lesser degree open to objections, but, from the immense amount of interest evinced in the matter, it may be with safety predicted that ere much time has passed a healthy and economical system will have been evolved. From the reports of the committee, collected from one hundred and fifty American cities, it seems that in forty-six of these dumping on and ploughing into land is the practice followed; dumping at sea or into a lake or large river is the plan pursued by fourteen cities; feeding to animals in forty-three cities; reduction to grease and fertilizer in seventeen cities; cremation in thirty cities. The first three of these methods may be dismissed briefly; they are all very imperfect, while feeding to animals is positively dangerous. There are then left the reduction and cremation processes between which to choose. In regard to the relative merits of these methods there exists in this country a wide difference of opinion. On the one side it is argued that cremation is wasteful and expensive; on the other, that in addition to being insanitary reduction to grease is also in most cases as costly as cremation. Mr. Rudolph Herring, speaking of the reduction system, says: "Reducing garbage to grease and fertilizer renders the mass of matter harmless, provided that the work is thoroughly done. It is found, however, that when this system is followed offensive odors are likely to pervade the neighborhood, and that the works will be looked upon as a public nuisance." The truth of these remarks has been proved in many towns, and at the present time a striking illustration of the fact is being afforded by Wayneport. The condition of affairs at this place has so roused public attention that the town board of health of Macedon recently engaged Dr. M. A. Vedder, of Lyons, to investigate and report upon the garbage-reduction works.

The results of Dr. Vedder's observations will hardly tend to tranquillize the minds of those residing in the locality in which these works are situated. After condemning *in toto* the position of the works, and after pointing out the fact that they are insanitary in a very high degree, Dr. Vedder ends by saying: "In short, the entire process is evidently an experiment, and is susceptible of very great improvement. Whether it can be perfected so as to become practically unobjectionable is a question difficult to decide, taking into consideration the present location of the plant. A practical point that is likely to be of wide interest in view of recent agitation in regard to sewage farms is in regard to the necessity for avoiding an impervious clay soil, especially if the surface is nearly level. The result is very much better, if such material be allowed to run over a sandy soil and down a slope, than if it be accumulated in a festering mass, breeding poisonous and foul odors year after year."

The reduction process in this country commends itself on account of its supposed economical advantages as compared with cremation. In America the cost of garbage disposal by cremation varies from three to ten cents per capita. In Europe the cost of refuse destruction is very slight. In some cases, in which the heat is used to generate steam power, there is said to be even a profit. The most interesting experiment in this connection is now being tried at Shoreditch, England, and is a practical application of the idea how to combine the destruction of refuse with the production

of electric light. Of course it would be as yet premature to pass a decided opinion as to the result of this trial, but it is estimated that under the new methods the cost will be reduced by something like two-thirds.

The conclusion arrived at by the majority of experts appears to be that the best system, from a sanitary point of view, is destruction by fire, that is to say, when the methods are efficiently carried out. The small and oftentimes questionable value of the refuse for fertilizing purposes should not be weighed in the scale against the greater value of improved sanitation.

THE GEORGIA FOOTBALL BILL.

Governor Atkinson, of Georgia, has vetoed the anti-football bill which was passed almost unanimously by both branches of the legislature. His objections to the bill are that "legislation which seeks to usurp the responsibility and functions of trustee, faculty, and parent, and take charge of young men and children in their sports, is fundamentally wrong; it is governmental paternalism of the most vicious and pronounced type." The governor says, however, that "some legislation may be necessary to modify the fierceness of football games," seemingly overlooking the fact that there is just as much paternalism in deciding upon the exact amount of violence permissible in a game as there is in prohibiting it. The bill forbade the "sport" only when money was charged for admission to the grounds where the game was played, so that it would have been still permissible to encourage "aggressive manliness," which the governor defined as "a quality amalgamated of courage, endurance, restraint, and the power to act surely and unfalteringly in an emergency —a quality which football tends to foster and to keep alive." But apparently an essential to the encouragement of aggressive manliness is a good pot of gate money.

News of the Week.

A New Public Hospital in Berlin.—There are at the present time three large public hospitals in Berlin, and authorization has recently been granted for the erection of a fourth.

A Woman's Work in Afghanistan.—It is pleasing to see a woman who has a real "vocation" for medical work make such an advance as that achieved by Miss L. Hamilton, formerly of Sundrum, in Ayrshire, Scotland. She was trained as a nurse in the Liverpool Infirmary, and afterward studied medicine in Brussels, taking her degree three years ago. After graduation she went to Calcutta and had begun practising, when the Ameer of Afghanistan offered her a fine salary if she would come to Cabul. She accepted the offer, though efforts were made to dissuade her. Since she has become the physician to the royal family she has gone on successfully treating the sick and enlightening the minds of the Ameer and his people, till she has won his full belief in the practice of vaccination; and now the entire population is being vaccinated with pure calf lymph produced close at hand, and a royal decree demands that no one shall escape this salutary proceeding. This has all been effected through the efforts of Dr. Hamilton.—*Woman's Journal.*

Temperance Drinks.—Not long ago attention was called in London to the popularity among tipplers of certain so-called temperance beverages, an analysis of which showed that they contained more alcohol than many straight-out goods in black bottles. The Massachusetts board of health has recently made a similar discovery concerning tonics and bitters, particularly those recommended as "temperance" drinks, in which the percentage of alcohol was found to vary from 13.2 to 41.6.

Long Life and Alcohol.—The secretary of the Order of Rechabites, a total abstinence workingmen's organization in England, has recently made a careful study of the vital statistics of the society as compared with other associations in which abstinence from alcohol is not a feature. He finds that at the age of eighteen the expectation of life is, among the Foresters, 44.74 years; among the Rechabites the expectancy is 50.62 years—a difference in favor of the latter of 5.88 years. Compared with the Oddfellows, the latter's advantage is even greater by 7.75 years. Applied to the whole population, the expectancy at eighteen among abstainers is better by 8.72 years. The mortality of the Foresters at the same age is 0.723 per cent. and of the Rechabites 0.589 per cent. The percentage of the Foresters' death rate to that of the Rechabites at eighteen is as 123 to 100, and at thirty-eight as 189.3 to 100. The conclusions reached by the compiler of these statistics seem to be corroborated by the report of an English life insurance company in which a distinction is made between the abstainers and the non-abstainers among the policy holders. Among the abstainers the expected deaths were 744, while there were only 432, a percentage of 58.06. Among the non-abstainers, the number of deaths looked for was 1,399, and the actual number who died were 1,131, or 80.84 per cent. of the expectancy. These figures are suggestive, yet there is consolation even for the moderate drinkers to learn that nineteen of them out of every hundred live longer than the actuaries' table says they should.

The Fruits of Sanitation in England.—Dr. Parkes recently published some figures showing the saving of life that had been effected in England during the reign of the present queen, through the efforts of sanitarians. He showed that the mortality from small-pox had diminished by ninety-six per cent. in 1891–95, as compared with the mortality in 1838–42. Since 1871–75 there had been a decrease of ninety-five per cent. in the mortality from typhus, and of sixty per cent. from typhoid fever. Since 1861–65 the mortality from scarlet fever had fallen eighty-one per cent. Diphtheria had prevailed very extensively in recent years, and owing to this greater prevalence the mortality was now very much the same as it was thirty years ago, despite the benefits of the new orrhotherapy.

Epidemics or measles and whooping-cough were as common now as when the Queen came to the throne. The mortality from tuberculosis had fallen forty-six per cent., though it was still high. Cancer, on the other hand, would appear to have increased. The deaths from drink were as numerous as they were twenty or thirty years ago. The general effect of improved sanitation was that six hundred thousand persons now reached the age of twenty-one years who would have died before that period sixty years ago. Notwithstanding this great prolongation of life there is no cause, Dr. Parkes thinks, to fear overpopulation, for the birth rate has been getting steadily lower.

Women Students at Berlin.—About two hundred women have been admitted to attend lectures this year at the University of Berlin, after having satisfied the authorities regarding their proficiency. The faculties chosen by them are those of philosophy, medicine, and jurisprudence.

Increase of Crime in Connecticut.—Some statistics recently compiled by Mr. T. D. Wells, secretary of the board of State prison directors, point to a remarkable increase of crime in Connecticut during the past quinquennium. The figures show that, while the convicts in the Wethersfield State prison increased in number only thirty-three during the fifteen years between 1877 and 1892, the increase in the five years since 1892 has been two hundred and three, or sixty-eight per cent. The prison is overcrowded, and twenty-two convicts are waiting in county jails for room in the State institution, the county jails themselves being filled with prisoners.

Almost a Buried-Alive Case.—The gentlemen who are agitating themselves and Europe into a society for the prevention of being buried alive will doubtless be glad to learn of the narrow escape of a New Orleans girl, thirteen years old, who was supposed to have died one day of yellow fever. The necessary certificate of death was given and the undertaker was notified to inter the corpse, the burial of yellow-fever victims in all cases being immediate. The undertaker was unable to go to the house at once and the funeral was delayed. In the afternoon, when final arrangements were made for the interment, the supposed dead girl opened her eyes, and it was found that she was not dead. The report did not say whether death really occurred later, or whether the resuscitation was complete and permanent as regards that particular illness.

Drug Adulteration.—According to a report of the Massachusetts board of health on the adulteration of food and drugs, there is the largest percentage of adulteration in drugs—50.3 per cent.—milk being next with 35.2 per cent., as found in 4,484 samples examined, while in food in general the percentage of adulteration is 11.6. The principal drugs adulterated or below the standard of strength were ether, alcohol, ammonia water and chlorine water, distilled water, calx chlorata, extracts of licorice and nux vomica, powdered opium, compound spirits of ether, spirits of nitrous ether, tincture of iodine, tincture of opium, and mercurial ointment.

The Women's Health Protective Association.—The annual meeting of this active society was held at the Academy of Medicine a few days ago. The election resulted in the choice of the following officers: *President*, Mrs. M. E. Trautman; *Vice-Presidents*—*First*, Mrs. Mary A. Newton, *Second*, Mrs. Esther Herman; *Recording Secretary*, Mrs. Theresa Barcalow; *Corresponding Secretary*, Mrs. M. E. C. Baker; *Treasurer*, Mrs. A. H. Spencer; *Auditor*, Mrs. E. L. Wakeman. In her annual address, the president, Mrs. Trautman, paid a tribute to Mayor Strong, Colonel Waring, and President Wilson, and stated that through their efforts the death rate in this city had been greatly decreased.

Small-Pox in Georgia.—It is reported that thirty counties in Georgia are suffering from a visitation of small-pox, and the silly local quarantines, of which the pernicious effects were seen during the recent yellow-fever scare, are being established. There have been upward of one hundred and fifty cases in Atlanta, and the board of health has adopted the honest course of publishing the number of cases reported daily in order to prevent a panic through the circulation of unwarranted rumors. The effect has, however, been to frighten all the little towns about, and they have quarantined against the city. A dispatch to the *Evening Post* says that compulsory vaccination has had the effect of frightening the country people away from Atlanta, many of them fearing that they will be hunted down on the streets and vaccinated upon the highways. This, of course, has nearly ruined the Christmas trade. Griffin, Rome, Gainesville, Cartersville, and other small cities are talking about quarantining, and the local papers in these and various other towns are advising the people to stay away from the capital. In La Grange it has been ordered a citizen cannot visit Atlanta without getting a permit from the mayor. The disease has also appeared at Rockhill, S. C., the seat of Winthrop College, where there are upward of five hundred young women, and has created great uneasiness. Every doctor in town is busy day and night vaccinating the inhabitants, and the governor has appointed a commission to visit the town and investigate conditions, in order to determine how to avert the threatened visitation.

The Hospital for Scarlet Fever and Diphtheria Patients.—This hospital will be opened on or about December 29, 1897. It is intended for pay patients, and is situated at the foot of East Sixteenth Street, facing the East River. The hospital is a private corporation, controlled by its own board of governors, and is not connected with any other institution. The president of the board of health and one of the health commissioners are *ex-officio* members of the board. Patients may be attended by their own physicians, if it is so desired. Visiting physicians, L. E. Holt, W. H. Katzenbach, George M. Swift, F. M. Crandall, W. K. Draper, R. J. Carlisle. Consulting physicians, E. G. Janeway, A. Jacobi, W. H. Draper, R. H. Derby, F. P. Kinnicutt, A. A. Smith, J. W. Brannan; consulting laryngologist, H. H. Curtis, resident physician, E. L. Dow.

Society Reports.

THE PRACTITIONERS' SOCIETY.

One Hundred and Thirty-Fourth Regular Meeting, Held on Friday, November 5, 1897.

DR. W. GILMAN THOMPSON, PRESIDENT, IN THE CHAIR.

A Case of Carcinoma of the Tonsil was presented by DR. CHARLES MCBURNEY. The patient was a man, forty-seven years old. In October, 1896, he first noticed a soreness of the throat, which did not increase very rapidly, and it was not until January, 1897, that an enlargement of the left tonsil was observed by his physician, who, suspecting syphilis, put the patient on specific treatment, which was continued for several months. The tonsil, however, continued to enlarge and ulcerated, and when the patient came under Dr. McBurney's observation last June it presented quite a large tumor, which was firm to the touch with an ulcerating surface which bled on handling. The disease had also spread to the pillars of the fauces, and crept up to the soft palate and edge of the tongue; it had also invaded the soft tissues on the inner aspect of the angle of the left jaw, although the bone itself was not affected. Microscopic examination proved the growth to be a carcinoma.

Operation: A preliminary tracheotomy was performed, so that the patient could be etherized without interfering with the field of operation, and to allow such tampons in the pharynx as would prevent blood from passing into the trachea and lungs. An incision was then made along the anterior border of the sterno-cleido-mastoid muscle from a point opposite the lobe of the ear to the thyroid cartilage. From the middle of this incision and at a right angle to it another cut was made upward and inward across the body of the jaw. The two triangular flaps were then dissected away, uncovering the submaxillary triangle. The external carotid artery and the facial vein were tied and the dissection was continued down to the internal carotid, which, together with the internal jugular vein and the pneumogastric nerve, were drawn to the outer side. The operation from this time on was comparatively simple. The larynx and trachea were first protected against blood by a sponge pushed to the deepest part of the pharynx. The pharynx was entered in front of the tonsil and the incision carried down behind it, completely removing the organ, together with a wide margin of tissue surrounding it. Besides the entire tonsil, the affected portion of the tongue and soft palate and all the lymphatic glands and connective tissue of the submaxillary triangle were removed; it was also deemed best to remove the left ramus of the jaw, on account of the disease of the soft parts on its inner aspect.

After the operation a splint was inserted in the mouth and left there for a number of days, in order to preserve the relation between the upper and lower jaws. This splint proved to be of little value excepting for a few days. The final result of the operation was remarkably good. For four days following the operation the man was fed by the rectum, and for the next six days the stomach tube was used; by that time the wound had healed sufficiently to permit him to swallow, and he made a rapid, uninterrupted recovery. He has good use of the jaw, and is able to masticate and swallow very satisfactorily.

Dr. McBurney said this operation was performed last July. Within the past few days he had noticed a small, indurated, and rather tender spot just posterior to the line of his incision; he thought it probable that this was a recurrence of the disease. If this patient had been presented for operation a few months earlier, the extent of the operation and the likelihood of recurrence would have been much less.

DR. JOSEPH D. BRYANT, who had seen the patient before the operation, complimented Dr. McBurney on the excellent result obtained. He inquired whether all the glands in the submaxillary triangle had been removed, or whether some had been found unaffected and were left behind.

DR. MCBURNEY said that he had removed all discoverable lymphatic glands and adjacent connective tissue. Some of the glands were very small and apparently healthy.

DR. ROBERT ABBE thought the result was excellent after such an extensive resection. He was surprised at the man's good masticating power.

DR. BRYANT said that about a year ago, after an amputation of the breast for carcinoma, he opened the axilla and there found one gland that was distinctly involved and a number of smaller ones that appeared to be entirely healthy. They were removed, however, and submitted to Dr. Dunham for microscopical examination, who pronounced them carcinomatous.

DR. MCBURNEY said that infection of the lymphatic glands in malignant disease varies in different patients. In some the disease seems to spread like wildfire, while in others it remains stationary after involving a few glands. In a case of carcinoma of the tonsil, which he operated on five years ago, the patient remaining entirely well up to the present time; there were several lymph glands involved, some as large as pigeons' eggs, and adjacent to these were glands which had remained entirely unaffected.

DR. BRYANT said that Dr. McBurney's patient illustrated the statement made by Kocher, that the prognosis in a case of this kind is not always in proportion to the extent of the disease. In other words, some of the best results have occurred in cases in which the disease had progressed to such an extent that an operative procedure was regarded as almost hopeless.

Adjourned Discussion. — The discussion of the paper, "The Clinical Value of the Widal Test," by Dr. Thompson, and the health board's circular, "Separation for Diagnostic Purposes by a New Method of the Typhoid Bacilli from the Stools and Urine in Cases of Typhoid Fever," submitted by Dr. Biggs, adjourned to this meeting, was resumed.

DR. G. L. PEABODY said: "Dr. Thompson has shown that the Widal reaction is obtained in certain cases which prove to be not typhoid fever. As we do not know for how many years after the occurrence of typhoid fever the reaction may not appear, it would be desirable in all such cases to learn if the patients ever had any illness like typhoid at any previous period."

DR. E. G. JANEWAY said that from his standpoint the Widal test had not proven very satisfactory. In a number of cases coming under his observation the test had failed entirely or had responded so late in the course of the disease that it was not required as an aid to diagnosis. To illustrate this he cited the following case: Last spring a young woman had been admitted to the hospital with suspected typhoid fever. The Widal test gave a negative result, and it was not until the patient had a hemorrhage from the bowels that the diagnosis was positively established. During the third week of her illness the test gave the usual typhoid reaction. In the mean time the patient's sister, father, and brother were brought into the hospital, and in all three of these cases the test proved negative. They had come from the same place as the first patient, and a diagnosis of typhoid was promptly made and afterward confirmed by the course of the disease. The speaker said he had seen a number of cases in which the Widal test, made comparatively early

in the course of the disease, had failed to respond. In one of the sixteen cases occurring among the nurses at Mt. Sinai Hospital, the reaction did not appear until convalescence. In regard to the reaction occurring in persons who claim that they have never had typhoid, Dr. Janeway called attention to the fact that this fever sometimes occurs without producing its characteristic symptoms or taking its usual course. He had seen a number of outbreaks in institutions, particularly among young people, when fully one-half of the cases aborted naturally within from three to ten days. The germ and poison of typhoid fever undoubtedly produce in different individuals a disease of very variable duration. In the outbreak of typhoid at Princeton College, many of the cases did not fully develop. The same is true of the epidemics that occurred at the Deaf and Dumb Asylum and at the Catholic Orphanage in this city. Only about one-half the patients in these institutions developed typical typhoid; in the rest the disease aborted.

Dr. F. P. Kinnicutt asked Dr. Janeway whether he thought the term "aborted" a good one to apply to those cases in which the disease never fully develops. Why should we not rather ascribe their brief duration to the fact that the infection is very slight?

Dr. Janeway replied that such mild cases may be due to the fact that the individual infected has sufficient resisting power to prevent the germs from growing—in other words, that he is less susceptible to the germs than are others; or they may be attributed to a mild degree of infection or a loss of infective power in the germs themselves. We see this same varying degree of infection or susceptibility occurring in the course of epidemics of other diseases. The speaker said that while he was an interne at Bellevue many years ago, an epidemic of typhus fever occurred, and both he and his hospital colleague were continually exposed to infection. Both were taken sick at the same time with the same symptoms; Dr. Janeway said he recovered after two or three days' illness, while his colleague died of typhus and his name is among the list of martyrs on the tablet at Bellevue.

Dr. Andrew H. Smith said he thought it quite possible that many cases of typhoid pass unrecognized. We see many cases of "walking typhoid," in the majority of which the patient is ultimately obliged to take to his bed, but a certain proportion recover without progressing further. The patients do not feel well, and still they are not prostrated to any marked degree. Doubtless the blood of such patients, who never knew they had typhoid, would react to the Widal test. The speaker mentioned the case of a girl who was admitted to the Presbyterian Hospital last winter with typical typhoid, which ran its usual course. In that case the Widal test was given five or six trials, at intervals of two or three days, but it was not until the fourth week that the usual reaction was obtained.

Dr. H. M. Biggs said he wished to emphasize the fact that at the laboratory of the New York health department, in every case when a definite reaction was produced in a dilution of 1 to 20, the reaction taking place within a time limit of ten minutes, it proved to be typhoid fever. The experience of the department now covered between five hundred and six hundred cases, and in every instance when the reaction was produced in the dilution of 1 to 20 the clinical results were entirely harmonious with the laboratory findings. The fact should not be lost sight of that the Widal test is quantitative and not qualitative. More than this, we must revise our ideas somewhat as to what typhoid fever is. If we confine the term to a disease in which there are intestinal lesions, we must also take into consideration the fact that there are typhoid infections in which the intestines escape. Cases of the latter class will give the Widal reaction, and in some of them the urine will contain typhoid bacilli.

Dr. W. Gilman Thompson said the object of the original paper on this subject was to discuss the clinical value of the Widal test. The speaker said he quite agreed with Dr. Biggs that the test should be a quantitative as well as a qualitative one. As regards the accuracy of the test, a number of cases are on record in which the reaction was obtained in a dilution of 1 to 20, and even 1 to 30, in patients who had not typhoid fever and never had had it. The possibility suggested by Dr. Peabody that some of these cases in which the reaction occurred may have had typhoid years before is quite true, but that does not render the test any less uncertain at the bedside. Many hospital patients are unable to give a satisfactory history. The speaker said he had reported two cases in which the reaction was obtained only during the relapse, the results of the test during the original disease being entirely negative.

Dr. Kinnicutt asked in regard to the frequency with which typhoid attacks the same person a second time. He thought this immunity against a second infection more apparent than real, and inquired whether it was due as much to the insusceptibility of the tissues or blood of the individual as to the improbability of his being exposed twice to the contagion. It is recognized that a second attack of typhoid fever is not uncommon in those who are exposed to the infection. He mentioned one case in which the patient had had three attacks.

Dr. Janeway said he had seen a second attack occur within three years after the original attack.

Dr. Peabody said we know positively that persons who have had syphilis or any of a number of other diseases are not susceptible to a second attack. He did not see why the same rule may not apply, at least to a certain degree, to typhoid fever.

Dr. McBurney said he had always been led to believe that many are frequently exposed to typhoid fever, and that comparatively few are liable to take it.

Dr. Janeway said that had also been his idea.

Dr. Beverley Robinson inquired whether people take diphtheria twice.

Dr. J. W. Brannan said he had seen a number of patients at the Willard Parker Hospital who had had at least two attacks of diphtheria, with an interval of only three months in some cases. The second attack may be very severe and even fatal.

Dr. Biggs said there is no doubt that diphtheria may occur more than once in the same individual. It is also true that one attack affords comparative immunity, and that an attack which runs its course affords much greater immunity than one which is cut short by the administration of diphtheria antitoxin. It is the difference between active and passive immunity.

Is Not the Mortality from Surgical Disease Unnecessarily Large?—Dr. Charles McBurney read this paper (see page 881).

Dr. V. P. Gibney said he quite agreed with the writer of the paper that unnecessary delays are often accountable for the bad results of an operation. It is certainly so in the department of surgery in which he is especially interested. The responsibility for such delays is often difficult to settle. In joint surgery it is a well-established fact that in some instances an efficient protection to the affected joint is conducive to an excellent result, and yet there are cases in which the lesion is so severe and extensive that no amount of protection we can give that joint will prove of any benefit to the patient. It is in those cases that we meet with stumbling-blocks; it is here that the extreme conservatives and the radicals clash. We all know there are exceptional cases in which nature has done extraordinary work, and such a patient is

brought forward as an example of conservative treatment. We do not hear so much of the bad results caused by delay, the amyloid degeneration, and other various complications that may set in, when operative interference is out of the question. In a diseased hip-joint, for instance, when the head, neck, and shaft of the bone are involved, we feel that amputation is the best thing, and yet we naturally postpone it until the patient is *in extremis*, and then it does no good.

Dr. Joseph D. Bryant said that the vulnerability of the tissues in different individuals, which was referred to by Dr. McBurney in connection with the time limit for operating in strangulated hernia, is subject to modification by so many extraneous conditions—such as the age of the patient, his previous health, etc.—that it must be regarded as a very uncertain factor. He saw no reason why prompt action should not be taken, irrespective of any lack of knowledge regarding the vulnerability of the tissues. When we come to the question of settling the responsibility for delaying an operation, the speaker thought it rested, first, with the patient; second, with the patient's friends; third, with the physician; and finally and not infrequently with the surgeon himself. How often, for example, will a woman who is suffering from a tumor of the breast keep the knowledge of it to herself as long as possible, and then perhaps confide it to a friend who will be equally uncommunicative? For sentimental reasons the patient may refuse to undergo an examination by a physician, or, even if such an examination is made and the physician suspects malignant disease, he may keep the suspicion to himself as long as possible. In the majority of cases the delay is probably due to the unwillingness of any one who is afflicted to recognize that fact. That feeling is very natural. Many physicians even are averse to having their urine examined or the heart listened to for fear that they may learn an unpleasant truth. Dr. Bryant said he knew of no way by which anything could be accomplished in this matter, unless it would be to instruct those who are in good health and inculcate in them the idea that when any abnormal condition of health appears they shall promptly and earnestly insist on being told what is the matter, and, if the case demands it, that the surgeon shall be called at the earliest possible moment to assist in determining whether his active services are necessary.

Dr. Peabody said he was not quite willing to plead guilty to the indictment that physicians in general cooperate with patients in their fancied security, and lull them gradually into the arms of death. He was willing to admit, however, that a certain number of physicians do delay unwarrantably in this manner. One explanation for this delay may probably often be found in the prejudice which exists against the surgeon in the mind of the patient. While the physician is often welcome in many households, the surgeon is looked upon as a necessary evil, to be averted or postponed if possible. The most sensible view to take is that in any case in which the services of a surgeon may become necessary he should be summoned as soon as possible. He should have an opportunity to see the patient at the earliest possible moment, and if it is then desirable to postpone operative interference the patient should remain under their joint observation. The physician should not take the reponsibility alone of postponing surgical interference in a grave case.

Dr. Janeway said that many elements enter into the question of delaying surgical operations. He has found that one of the most potent causes of delay is the knowledge possessed by the patient that some friend or relative had undergone a similar operation and died. Many refuse to be operated on, or delay the operation as long as possible, because they know of similar cases which were operated on and resulted unfortunately. Another cause for the delay in many cases is the natural desire on the part of the patients' friends to keep them in ignorance of the real nature of their ailment. Some surgeons occasionally make the statement to the patient that unless an operation is performed he cannot recover. Such prophecies sometimes prove false, and are apt to give rise to a suspicion in the minds of the laity that the surgeon is anxious to operate.

Dr. Robert Abbe said that in considering the present surgical mortality rate we should bear in mind the fact that the amount and class of surgery done twenty years ago cannot be compared with that done to-day. The class of cases which still contributes most to the large mortality is that in which there has been too much delay before operation—the neglected cases. These patients, when they come to the surgeon, are in a practically hopeless condition. They seem so at the time to the surgeon; yet occasionally one such patient survives operation, and with that fact in mind the surgeon operates. These help to swell the surgical mortality—cases, nineteen out of twenty of which should never have been operated on. Hence we should study to learn the limit of possible surgical relief. Take, for example, general septic peritonitis; we all know that an operation for this condition when very far advanced usually proves unavailing, and yet very grave cases have been reported as saved, in a few instances. Dr. Abbe said he had studied a large number of these cases, and found that in every instance when albuminuria was present and of very recent onset the case proved fatal. The cases which recovered were those in which there was no albuminuria. If a case of acute septic peritonitis has developed a septic albuminuria from a choking of the renal vessels, the case is hopeless. One important method, therefore, by which the surgical mortality can be largely reduced, is to refuse to operate in what appear to be hopeless cases when more careful study proves operation to be unjustifiable. The occasional successes and falsely reported cases in literature should not be permitted to lure the surgeon on. The occasional refusal of the surgeon to interfere, when his intelligence and conscience justify him in doing so, will ultimately command a larger number of cases brought to him in the incipiency of disease, and thus finally reduce the mortality credited to operations.

Dr. A. H. Smith said that last summer he saw a case of carcinoma of the stomach which he regarded as absolutely hopeless, and so reported to the family. A surgeon who had been highly recommended to the family was called, with the consent of Dr. Smith, merely to satisfy the friends; but to the amazement of Dr. Smith an operation was advised. He then insisted that the family should select another surgeon before proceeding. They did so, and his opinion coincided with that of Dr. Smith. The patient died a few weeks later.

Dr. Beverley Robinson said that, speaking as a general practitioner, he usually prefers to refer his operative cases to a general surgeon rather than to a specialist. The latter, as a rule, does not operate any better than the general surgeon, and he is often led to do an operation which the general surgeon would not do. In all cases which demand it, the opinion of the surgeon should be obtained as soon as possible, providing he is a man who has achieved a position in his profession which has rendered him conservative, so that he will refuse to undertake an unnecessary or overhazardous operation.

Dr. McBurney, in closing the discussion, said that, while the surgical mortality can be easily reduced by refusing to operate on hopeless cases, there is another and better way, and that is to have those patients who are now brought to the surgeon too late

brought in time to be operated on and saved. He agreed with Dr. Bryant that the time limit can never be accurately defined, but in many cases there is a time limit which can be scientifically discussed by the physician and the surgeon. In strangulated hernia, for example, there is a time during which the patient can be successfully operated upon and after which he cannot. If this question of the time limit should receive more serious consideration, we would not so often hear said: "I do not see why we should not wait until to-morrow." In reply to a question, Dr. McBurney said that he never consents to operate unless he believes that the patient may benefit by the operation. The surgeon should never allow himself to be influenced by sentimental reasons, if it is his deliberate opinion that the operation cannot possibly do good.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 27, 1897.

WARREN COLEMAN, M.D., VICE-PRESIDENT, IN THE CHAIR.

Tuberculous Lymph Nodes from a Case of Chronic Bronchitis and Emphysema.—DR. J. H. LARKIN exhibited under the microscope a section of a lymph node taken from the root of the lung of a man, forty-five years of age, who had died of chronic bronchitis and emphysema. There had been no other tuberculous inflammation in the body. The autopsy showed intense venous congestion of the kidney and a nutmeg liver, with a few adenomata scattered throughout the liver. Along the root of the lung the lymph nodes were very much swollen. Around the pericardium they were also much swollen, some of them being as large as a hazelnut. A thorough search was made in the lungs and other organs for tuberculous foci, but none was found. On cutting open the lymph nodes they were found to be nearly three-fourths cheesy, the microscope revealing diffuse areas of cheesy degeneration. Dr. Larkin said that he had ground up some of these cheesy nodes with decinormal salt solution, and had then injected two cubic centimetres of this fluid into each of three guinea-pigs. After three weeks one died, but the autopsy was negative. The other two were killed at the end of eight weeks, and in these animals the post-mesenteric glands were very large and cheesy, and there were several small foci in the liver and spleen. Some pseudo-tubercles were found in the lungs. He had collected the lymph nodes from the guinea-pigs, and had made sections of these also. One of these sections from the post-mesenteric glands was also shown under the microscope, stained for tubercle bacilli. The specimen exhibited several bacilli, which corresponded morphologically with tubercle bacilli. The specimens were presented because of the interest attaching to their occurrence in a case in which death had been due to chronic bronchitis and emphysema, with no other evidences of tuberculosis in the body. It would seem from the findings in this case that the lymph nodes served not only as storehouses for noxious products and various kinds of pigment, but also as storehouses for bacteria—not only the ordinary bacteria always found in the trachea, but for pathogenic bacteria. The case also illustrated one of the ways in which a person might become infected with the tubercle bacilli, *i.e.*, the bacilli first finding a lodgement in the lymph nodes, and afterward, probably as a result of some exposure to some weakening influence, being distributed to the body at large.

DR. HENRY HEIMAN said that it was interesting to recall in this connection that Billroth thought he had observed tuberculous meningitis following operations on tuberculous glands of the neck.

DR. WARREN COLEMAN asked Dr. Larkin what was his view of the ordinary channel of infection in the lung, whether through the smaller bronchial tubes or first through the lymph nodes. He had in mind those foci of infection so frequently met with at the apex of the lung.

DR. LARKIN said he thought a large dose of tubercle bacilli might get in through the bronchi without passing through the lymphatic channel, and might there set up a diffuse tuberculous pneumonia. In other cases a few tubercle bacilli might be lodged in the lymph nodes and remain quiescent for a longer or shorter period of time. The anatomists had possibly thrown a little light upon this matter by referring to the unequal angles of divergence of the bronchi from the trachea. This, of course, was only an attempt to explain why tuberculous deposits occurred by preference in the apices of the lungs, but did not explain the simultaneous involvement of both apices.

DR. COLEMAN said that a most plausible theory in connection with the location of these processes at the apex, and of the channel through which the bacilli passed, was that which assumed that these organisms were taken up by phagocytes and carried into the lymph channels, and that, instead of remaining in the glands at the base of the lung, they passed through these for some unknown reason, and were then carried through the lymph channels to the apex.

DR. LARKIN said that in his case undoubtedly the bacilli had been seized by the phagocytes and had gotten only as far as the nodes; but if the tubercle bacilli did get farther it was hard to understand why the apices should be selected by preference.

DR. JAMES EWING said that he could not see how the lymph nodes at the base of the lung could play a part in tuberculosis. All experimental studies regarding the reasons for the lodgement of tubercle bacilli in the apices by preference had led to the conclusion that it depended upon the character of the blood supply there, and upon mechanical conditions affecting the aeration of those parts of the lung.

DR. COLEMAN said that the statement just made about the circulation at the apex might explain the lodgement of organisms there rather than in other parts. Some years ago he had made some incomplete experiments bearing on this question. They consisted in making an animal inhale lampblack, and also in injecting this lampblack into the pleural sac. It was found in the course of half an hour that these pigment granules had been taken up from the trachea and large bronchial tubes, and had been distributed through the lymph nodes under the pleura and over the whole surface of the lung. These experiments had influenced him largely in arriving at the opinion already expressed.

DR. LARKIN said that in autopsies on cases not supposed to be tuberculous the lymph nodes received very little consideration, yet a large percentage of these lymph nodes in patients dying of diseases other than tuberculosis contained foci of tuberculous inflammation. The case from which his specimen had been taken was only one of a series of about thirty autopsies, in which the lymph nodes had been collected from the roots of the lungs which contained ordinary cheesy areas.

DR. COLEMAN said that an English observer had recently promulgated the theory that tuberculosis, when in a condition to be recognized by the physical signs, was really in its second stage, and that the infection not infrequently gained an entrance to the body through the alimentary tract and mesenteric glands.

Autopsy Made Months after Death.—DR. JAMES EWING presented the viscera from a case on which an

autopsy had been made five months and eight days after death. He was enabled to present this interesting material through the kindness of Dr. A. Jacobi, whom he had assisted at the autopsy. The clinical diagnosis had been tonsillitis and nasopharyngeal hemorrhage; the anatomical diagnosis was peritonsillar abscess and retropharyngeal abscess, with rupture of the right internal carotid artery. An embalming fluid of unknown composition had been injected into the median basilic vein. The body had been interred in dry gravel in a wooden casket, surrounded by the usual outer box. The body itself was rigid and the skin much desiccated, but the features were surprisingly well preserved. There was a large abscess cavity around the tonsil and behind the pharynx, and about one and one-half centimetres above the origin of the internal carotid artery was an irregular opening, five centimetres in circumference, communicating with this cavity. The viscera were so desiccated as to be tough and almost cartilaginous. The spleen and kidneys were remarkably well preserved, and, strangely enough, with the ordinary methyl blue stain it was possible to demonstrate the presence of numerous colonies of cocci around the wall of the abscess cavity.

Dr. Coleman said that in the only case of this kind that he had seen the sections of the kidney were in as good condition as was the specimen just presented, and the hardening was almost as perfect as if it had been done in the laboratory on small pieces of tissue.

Dr. Larkin said that the most approved method of embalming at the present time seemed to consist in puncturing the different viscera with a trocar, instead of injecting the fluid into the vessels. Great care was taken to extract as much blood as possible.

Dr. Ewing said that in the autopsy he had reported there had been no punctures in the skin or viscera.

Preservative Injections in the Intestine.—Dr. Henry Heiman said that about one years ago Dr. Henry Power had conducted certain experiments regarding the value of formalin as a preservative in the intestine. Dr. Heiman said that he had varied these experiments by injecting two to five per cent. solutions of formalin into the rectum of five children who had suffered from gastro-enteritis. For comparison he had examined three cases of gastro-enteritis in which no formalin solution had been injected. The injection had been made immediately after death. It was found that by this early use of the formalin injections the mucous membrane was at once fixed for hardening purposes, thus preserving more epithelium and giving a more clearly defined picture. The autopsy could be made at the usual time. He had used an ordinary irrigator, and had found by experiment that the correct pressure was obtained by elevating the reservoir about six or eight inches only. His plan was to sew the nozzle into the rectum and allow the fluid to run in for some time, twelve to twenty-four hours in some cases. The fluid would reach half-way up the ascending colon, and even the parts in close apposition to those injected became hardened. Specimens were exhibited under the microscope showing the gut in cases so treated, and also those not preserved in this way. The solution used was a 2.5-per-cent. solution, made from the ordinary commercial (40 per-cent.) formalin solution. It did not produce the shrinkage that other hardening-fluids did.

Dr. Ewing said that he had followed the experiments of both Dr. Power and Dr. Heiman, and the results were certainly a marked improvement on those of the ordinary method of leaving the body until permission had been obtained for an autopsy. The mucous membrane, muscular coat, peritoneum, etc.—in fact, all except the superficial epithelium—were very well preserved. It did seem, however, that the injection fluid did remove some of the superficial epithelium; hence the specimens were not so perfect as those obtained from bodies in which the autopsy was made immediately after death, as after electrocutions. The method nevertheless was to be highly recommended for ordinary cases when one desired to examine the intestinal epithelium.

Dr. Heiman said that this method might be employed in diseases of the intestine. He wished here to acknowledge his indebtedness to Dr. Rowland G. Freeman for the material experimented upon.

Dr. Coleman said that the method had been applied recently at the Charity Hospital in cases of gastric carcinoma for the purpose of preserving the gastric mucous membrane for subsequent examination. The result should be even better than in the intestine, because it would stop the self-digestion of the stomach.

Dr. Larkin said that he looked upon formalin as a very tricky preservative, and it was unfortunate that experiments in this direction had not been made with some other preservative as, for example, Müller's fluid. If formalin was used alone, the effect on the staining properties of cells was not so good as if a combination of formalin with alcohol or Müller's fluid was used.

Dr. Coleman remarked that it was generally admitted now that formalin caused swelling of the cell protoplasm, and hence destroyed the intimate structure of the cells to some extent.

Dr. Heiman said that when formalin was added to ordinary chest serum he had found that it did not coagulate it. Wassermann had stated that the addition of formalin to serum prevented its coagulating when heated, and he had found that if egg albumen was placed under the same cover with formalin it would become coagulated after a time. It was evident that formalin acted very differently on different albumins.

Dr. Coleman said that one of the chief virtues of formalin was that it would coagulate the liquid in the alveoli in a case of pulmonary œdema, so that the condition might be demonstrated to students. He had not been able to do this with any other hardening agent.

The society then adjourned.

Correspondence.

OUR LONDON LETTER.

MEETING OF GENERAL MEDICAL COUNCIL, SIR R. QUAIN'S HEALTH, EXIT THE UNQUALIFIED ASSISTANT, MIDWIVES AGAIN, NEW MEMBERS—DR. RENTOUL EXPLAINS OR EXCUSES HIS RESIGNATION—MEDICAL SOCIETY—GLASGOW INFIRMARY—EDINBURGH—TYPHOID—UNIVERSITY PROPOSAL—CENTRAL HOSPITAL COUNCIL—DEATH OF DR. HEDDLE.

The General Medical Council met on Tuesday. The venerable president, Sir Richard Quain, was unable to be present, although his health has materially improved. It is said by those who see him that his mind is unclouded and alert. The letter he sent to the council, sketching the course of business and the subjects coming forward for discussion, shows how thoroughly he still grasps the details of the council's work and duty. This is the first time for thirty-four years that Sir R. Quain has been absent from the council, and regret was naturally expressed by his colleagues, who, on his recommendation, requested the chairman of the business committee, Sir William Turner, to act as his substitute.

The most important act of the session was the decision of the council no longer to tolerate unqualified

assistants. Notice is to be given that their employment renders practitioners liable to be removed from the register, on a charge of "infamous conduct in a professional respect." There was a difference of opinion as to how long notice should be given, but the council has for so long distinctly denounced and punished "covering" that the new departure is only a step in advance. It is strange the determination has been so long delayed. Students in their last year may be utilized as "pupils" for a period of six months.

The midwives question again came up for discussion on the report of last year's committee on the subject, which recommended the appointment of a further committee to report on any bill which may be introduced into Parliament next year. A resolution to the effect that midwifery cannot be safely practised by those who are not fully qualified in medicine, surgery, and midwifery, after a good deal of discussion was laid aside, and it was eventually resolved that it is inexpedient to adopt an abstract resolution which might prevent full consideration of any future bill submitted by the government.

Dr. William Moore was obliged by ill health to resign his seat in the council, to the regret of his colleagues. His successor will be appointed by the privy council.

Sir C. Nixon took his seat as the new member for the Royal University, and Mr. Horsley as the newly elected representative of the registered practitioners, in the place of Dr. R. R. Rentoul. Dr. Rentoul has now issued his explanation of his resignation of his seat. It resolves itself into dissatisfaction with the profession for the feeble support accorded him in his schemes of reform, and the expenses he incurred. Undoubtedly the profession is extremely difficult to rouse. Its apathy must appear to so zealous a reformer as Dr. Rentoul almost as bad as opposition. It is easy, therefore, to understand his feelings. But there is something to be said on the other side. Having sent Dr. Rentoul to the council, we felt our affairs were safe in his hands, that he would do all that was possible in the circumstances. But it was a mistake to send him. His zeal burns within him, and no wonder the stolid opposition of the council turned that zeal to impatience. Then the charge of deserting him pecuniarily is too true. He is still nearly £100 out of pocket by his experience. It is a pity, but reformers have usually experienced similar discouragements.

Then some of Dr. Rentoul's views are not acceptable to many. He proposes that practitioners should be required to pay £1 a year to the council, to enable it to do more work. Now the authority to practise has always been paid for once for all to each licensing body, and so overcrowded is the profession that there are hundreds to whom £1 a year would be a serious item. They would neglect to pay it, be left out of the register, and so be lost to all control, and it would be more difficult than ever to distinguish between qualified and unqualified men. Again, the council has hitherto given little satisfaction. For thirty years it has gone on its way and stolidly refused to reform. Would it be wise to add another £30,000 a year to the £10,000 it already spends in doing next to nothing? Even to please Dr. Rentoul, it can scarcely be expected we should care thus lavishly to endow a body which he himself declares must be radically reformed. Again, he wants an increase in the direct representatives, so as to overcome the resistance of the corporations. This will never be granted, as the government would so far enlarge the council, and the addition of one or two more would have no effect. Besides, direct representation has been shown to be a failure, and there is no hope of reform being furthered by its means. The only effective plan would be to reform the corporations themselves.

The Medical Society's meeting on Monday opened with a paper by Dr. Samuel West, on pyo-pneumothorax. He gave the history of a case of several months' duration, which terminated in recovery about seven months after free incision. Dr. West deprecated the too common practice of leaving such cases to expectancy, and opposed the notion that operation only hastened the end, as well as the frequently expressed idea that pneumothorax tended to prevent tuberculosis. If pyo-pneumothorax were to be treated as empyema now is, better results would follow. He advised operation in the early stage when the symptoms were urgent or paracentesis failed; later on when the effusion was purulent or sero-purulent.

Dr. D. H. Hall related several cases in which the results of operation were disastrous, owing to the lung not expanding. Though when the lung was healthy operation might give good results, when the lung was diseased this seldom occurred. Dr. Thorowgood did not advise operation, except when urgent symptoms appeared.

Mr. Sheild mentioned a case complicated with gangrene of the lung, followed by recovery after operation. He remarked on the risk of anæsthesia in such cases, and recommended the position of the patient to be such as to permit free lung play. Rapidity of operation and no fixed dressing for a day or two were also important.

Dr. Bowles mentioned two published cases of "death under chloroform," which he believed were caused by the patient inhaling pus when turned over for making the incision.

Mr. S. Eccles then read a paper on the "Mechano-Therapy of Movable Kidney." He had had twenty-one cases since 1892, of which sixteen were treated by rest and abdominal massage for from two to eight weeks. He urged that treatment of this kind should be fairly tried before operation could be recommended, supporting this view by details of cases which were greatly improved.

Mr. Freyer said he had never seen a case benefited by massage or mechanical methods, although he had seen one in which all the fat around the kidney had disappeared from massage. Dr. Sansom said patients should not be told they had movable kidneys. Dr. Hall had known a case so diagnosed cured by a pad and bandage.

The misunderstanding at the Western Infirmary of Glasgow threatens to end in a deadlock or a scandal. Already a number of letters have appeared in the local papers. A general meeting was held yesterday, but I hear no result was arrived at.

At the Edinburgh Royal Infirmary a great improvement has been carried out. The surgical out-patient department had been completely separated from the corridors and side rooms attached to the wards, where visitors have often been amazed to find patients waiting, for out-patients may often be inadvertently purveyors of infectious disease.

The typhoid epidemics have been less fatal this week, but some new cases occurring suffice to show they are not yet over.

A general committee has been formed to promote the establishment of the proposed University of Westminster.

The first meeting of the delegates of the twelve teaching hospitals, calling themselves "The Central Hospital Council," has been held. Whether the other hospitals will recognize the right of the larger to dictate to the smaller remains to be seen.

The death is announced of Dr. M. F. Heddle, F.R.S.E., M.D., emeritus professor of chemistry in St. Andrew's University.

THE ROUTE TO CAMDEN, S. C.

To the Editor of the Medical Record.

Sir: In the Medical Record of November 27th, in the mention of the winter health resorts of the Carolinas, I think some injustice is unintentionally done to Camden, which is a very popular resort. It is said in the article in question that to reach Camden you go to Charleston, S. C., and thence by rail to Camden. This is a very roundabout way, and very inconvenient. The way to get to Camden is to come to Rock Hill, S. C., by the Southern, and thence by the O. R. & C. (good connection) to Camden, it being only twenty-four hours' ride from New York by this route.

Knowing your desire for exactness, I write this correction. John W. Corbett, M.D.

Camden, S. C., November 29th.

"IN THOSE DAYS THERE WERE DEVILS" —AND NOW.

To the Editor of the Medical Record.

Sir: In your issue of December 4th Dr. James Weir, Jr., tells interestingly how "In Those Days There Were Devils." The same issue contains proof that in these days and your printing-office the devil is at his ancient tricks.

Having written to you lately correcting a misstatement in the lay press of the results of medical prosecutions conducted by me, and having also suggested that it would be agreeable to me if you should see fit to correct the error as a matter of news without use of my name, I find to my terror that the printer, proofreader, or more probably the "devil," has honored me with the medical degree, power to confer which *causa honoris* was abolished in this State some years ago, and has made me *prima facie* guilty of "appending the letters M.D." to my name; for which misdemeanor, if convicted of it, a considerable fine might be imposed upon me. Pray correct this mistake in any fashion you see fit, or, failing to do so, be prepared, if I am arraigned in court for false use of the sacred letters, to come and testify that they were not appended to my name by me, but by the Medical Record, which has not yet renounced the devil and his works.

By dropping the figure "2," the printer has also regulated the practice of medicine by chapter 5 instead of chapter 25 of the general laws.

W. A. Purrington.

THE ABUSE OF MEDICAL DISPENSARIES.

To the Editor of the Medical Record.

Sir: Permit me to contribute my mite to the literature of dispensary abuse. If one is to judge from the various articles that appear periodically in the medical journals, expressing opinions as regards the causes of dispensary abuses, there must be a great commotion in the medical profession; the nice round incomes must have been reduced to such a low figure that silence is not only not gold but not even copper.

I shall not attempt to mention the various causes given by an army of contributors; space will not permit it. What I want to say is this: After so much has been said and written on the subject, not one person, as far as I know, ever mentioned the primary cause, according to my opinion, of all this charity abuse, reduced practitioners' incomes, increased quackery, and even some of the suicides of practitioners which are attributable to the same cause—all symptoms of one particular affection.

This dispensary epidemic is not limited only to the cities of the East; its ravages are spreading like a prairie fire all over the country—east, west, north, and south.

Now to come to the point. The medical profession, like any other, is subject to the simple law of economics of supply and demand. The proportion of medical men in this country is in inverse ratio to the population. But, ignoring this simple rule, medical colleges spring up like magic in every hamlet of the country. These new-born so-called institutions of learning are naturally struggling to maintain themselves; an unhealthy competition is the result. Dispensaries are created to supply material for teacher and student. The worthiness of the applicant for free treatment is overlooked. The teacher is proud to add professor to his title, and sometimes with it a temporary increase of his fee and income. The ambition of adding the title of professor to the usual M.D. seems to be quite epidemic in our part of the country. To accomplish this an "institution" is started in some two-story frame building and extensively advertised. Students "must" be procured; the institution "must be maintained"! Is it any wonder that such a degenerate parentage gives birth to a diseased progeny? These are, no doubt, the "Youngbloods" of Dr. T. J. Hillis' article. Quackery and charlatanism are their only art and science. The more able and honest, for the lack of compensatory practice, offer themselves gratis to hospitals and other charitable institutions. The people's respect for the medical profession is lessened, and with it the income of the latter. Many of the medical institutions of this country have no other excuse for their existence but some doctors wanting to be professors.

These are, in my opinion, the causes that lead to dispensary abuse, increased poverty, and decreased respect for the medical profession.

Berthold Weisenberg, M.D.

41 J New Avenue, Milwaukee, Wis.

THE TWENTY-FIVE-CENT DOCTOR.

To the Editor of the Medical Record.

Sir: The cohesion of the organization of society is the measure of its civilization. "The wild man of Borneo" knows not a chief, but sixty millions of Americans, in greater or less degree, hold their President in reverence. Individualism is barbarism, is anarchy, while the union of like or congenial forces, be they bad or good, in the long run trends toward progress. Somewhat through invention, more through wise legislation, but most through their organization, have manual labor and the mechanical trades grown into the respect and dignity that they hold to-day. Combinations of capitalists crystallize the effort of individuals into profits for themselves, while in turn the union of those individuals that produce these profits forces the capitalists to a division of these profits, to the benefit of the private condition of each. The peoples that are born with the genius for unity of action are conquerors. The gay, the brilliant, the iridescent Celt, by the sluggish Saxon is ever borne down.

That which has, more than anything else, made modern medicine what it is, had its origin when the quacks, the charlatans, and the empirics of the long ago, for their own betterment formed a sort of Gypsy union, out of which has grown what we are pleased to call "our code of ethics."

"*À propos* of nothing," I have never seen a physician break through that code with any lasting benefit to himself, for in the process he is sure so to rend the phylacteries of his own medical reputation that his last estate is worse than his first.

The true meaning of the code is that the physician

should not do anything to degrade himself, to degrade his brother practitioner, or, what is of far more moment, degrade the dignity of his profession.

Most nobly is the MEDICAL RECORD warring against the abuses that have crept into the profession in the large cities, but we in the country and country towns "have troubles of our own." In every country village of a thousand or more inhabitants will be found two or three circles of men banded together in some order, as Red Men, or Foresters, or under some similar title. These fraternal orders put the medical attendance of their members up at auction to the lowest bidder, or else try to make ridiculous terms with whomever they may. In many places the remuneration for this work is $1 a year per member of the society.

Another abuse is that in this same class of towns are growing up what are called "medical clubs." These admit to membership men and women, old and young alike, anybody that will pay the pittance, which is usually about $1.25 per annum.

The next grievance on the list is the cheap insurance business. There are a number of companies that pay 25 and 50 cents for some form of examinations; and these companies do their largest business among the classes that are able to pay decent medical fees. Only recently I was almost entrapped into lending myself as an examiner for one of these concerns. An agent came to me and wanted me to make out an application to be appointed an examiner. I asked him if it was a twenty-five-cent company, and he replied in the negative. After the application was made out, he said that for a simple "inspection," whatever that may mean, the company allowed twenty-five cents, and for something else in the way of examination fifty cents. I tore up the application and told the agent to get out of the hole the carpenter left as quick as he could. As he took his hat he snapped: "There's lots of docks older and smarter than you be that's more'n glad of the business." Ay, there is the rub—"Glad of the business." I informed him that I was not a twenty-five-cent doctor, at any rate.

As it fell out, there now drives eight miles from another village a doctor "older than you be," to attend to this company's precious interests. However, I give the man credit for being thoughtless about the matter, as he seems to be a very decent sort of a fellow.

The last and meanest degradation of them all is the acceptance of medical practice farmed out for so much a year by rural town boards. The chief occupation of these boards is to cut down all town expenses except their own fees, at least until the next election. Under my observation is a town containing a rural and village population of two thousand. This township covers an area of about ten miles square. The town board has all the poor in this town medically attended for $30 a year. This is blank, black barbarism. The idea that, because a human being has committed the heinous crime of being poor, in the hour of his illness and distress he must accept the medical services of a person that is willing to receive for them whatever a parsimonious town board of hayseeds is pleased to grant! It is sickening!

Is there any remedy for these evils? To a degree I believe there is. Public opinion is but the aggregate of private opinions. Public evils must be remedied by public means. Let the State society appoint a man from each county society to interview the physicians in each county that are engaged in this nefarious business. If they will consent, let them, with the physicians who are above degrading themselves, sign an agreement that they will outlaw the evils that have been mentioned. Then let the names of those holding the degree of M.D. that will not sign the agreement be reported to both the State and county societies. At stated intervals have a list publicly printed and circulated, both by the State and county societies, of those who are doing an illegitimate business.

The remedy is weak, you say; it is. But it seems the best we have. Many that would not sign the contract would become out-and-out quacks. Let them go. Better a dozen enemies outside the walls than a single traitor within.

To me the greatest marvel in the world is the brainlessness of man. Let those who believe in the union of ourselves for our own protection, whenever fitting time presents, act as propagandists among those who are destroying what little of unity there is. Tell them, as they degrade our services by offering them to the cheapest bidder, they, Hibernian-like, are sawing off the limb on which they perch. Tell them that in this crowded world there is no room for the individual unless he stands in unity with those about him; tell them that they are undermining the monument of success which they hope to climb.

W. C. SEBRING, M.D.

PINE BUSH, ORANGE COUNTY, N. Y.

THE DISPENSARY ABUSE OF TWENTY YEARS AGO.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: One feature of the correction of the abuses of medical charities has not been sufficiently brought out in the recent consideration of this matter.

The managers of dispensaries have too generally been spoken of as wholly responsible for the evils which exist, and entirely opposed to any measures looking to their amelioration or suppression.

Just twenty years ago this month, a committee of gentlemen was appointed by the State board of charities to "make inquiries as to the misuse of the benefits of the medical charities of the city." (See first report of committee to State board of charities.)

This committee made its report on May 6, 1878, and stated that they have confined their inquiries to the "general dispensaries, and have submitted the answers of these dispensaries *verbatim*."

This committee was composed of Drs. Joseph W. Patterson, C. R. Agnew, Henry E. Pellew, Edward Oothout, John Sherwood.

The answers elicited by these gentlemen twenty years ago are not only very interesting reading now, but prove very conclusively that the dispensaries were not then averse to having such regulations as would prevent abuses, and while we have no record of the opinions of the managers of the present day, save and except the writings and public speeches of one of the managers who has seen long service (J. Harsen Rhodes, in his addresses before the conference of United Charities and State Medical Association), we know from personal interviews with many prominent dispensary managers that the sentiment is unchanged.

From the MEDICAL RECORD of August 17, 1878, I quote from an editorial review of this report to the State board of charities: "It would appear . . . from this report . . . that the medical profession is not alone interested in checking the growth of the evils connected with our dispensary system, but that distinguished laymen are taking the matter in hand and are working in the direction of reform, with an earnestness of interest and a sincerity of purpose that are worthy of the cause."

From the report itself we note only a few of the answers. There were nine questions asked of the dispensary managers, viz.:

"1. Is it desirable that the general dispensaries should confine their operations strictly to their respective geographical limits?

"2. Is it in your opinion expedient, with a view to restrict the benefits of your institution to the really

necessitous poor, that inquiries should be made of each applicant as to his or her pecuniary ability and special circumstances, at the time aid is asked for?

"3. What, in your opinion, should be the minimum income of the applicants, as modified by the number in the family, and other special circumstances, to deprive them of the benefit of your institution?

"4. If you are of opinion that such minimum of income should be enforced, would it not be necessary and desirable to designate some employee of your institution to act as registrar?

"5. Would this involve much difficulty in your case? If so, please state the points of difficulty.

"6. What course would you recommend for adoption with respect to those applicants who may be denied aid?

"7. Is there, in your opinion, any mode, not open to abuse, by which the names and addresses of good druggists and of doctors residing near such applicants, and willing to treat such cases for a small fee, may be communicated to them?

"8. Is it not, in your opinion, very important to require your visiting physicians to report to your board regularly any want of proper sanitary arrangements in the dwellings visited by them, that such information may be formally and promptly brought to the notice of the board of health?

"9. If, by the conditions of your act of incorporation, you are prevented from making any charge to applicants for relief, would it be, in your opinion, expedient to apply for any legislative change in this respect?"

Question I., answers: New York Dispensary—"We consider it desirable that the general dispensaries should confine their operations strictly to their respective geographical limits, for the reason that the work is more systematic, economical and orderly, and more easily understood and controlled.

"To the visiting physicians who visit patients at their houses, in consequence of their inability to come to the dispensary, it is indispensable that the geographical limits of their respective districts should be strictly defined and observed. In fact, it would be impossible to carry out effectually the objects of the dispensary system if the territory is not limited, as the services of the physicians would be subject to the calls of patients from all parts of the city, thus taking unnecessary time, labor, and expense. Great confusion and conflicting authority and obligations, between or among the dispensaries and their employees and officers, might arise or be occasioned.

"The New York Dispensary now has for its limits all that part of the city on the west side south of Spring Street, and on the east side all south of East Fourteenth Street, First Avenue, Allen and Pike streets.

"This large area is divided into four subdistricts, of which the limits are defined and well known, and to each of which the work of one of the district physicians is confined. These visiting physicians are paid salaries by the dispensary, and it is not too much to say that, if they were to be called into other subdistricts, much less into the districts of other dispensaries, it would be impossible for them satisfactorily to perform their duties. The number of visiting physicians and their expenses would thus be greatly increased.

"On the other side, it is difficult to perceive any advantage to the patients or to the physicians of the dispensary, to throw open the field to distant residents, so long as there are other good dispensaries and visiting physicians who may be called upon.

"In fact, if there are no limits, the aid to be furnished would be subject to the mere whims and caprices of the patients.

"Again, as to the patients who call for relief at the dispensary. While it might be harsh to refuse any relief to a poor applicant residing beyond our limits, and a thing rarely done at the New York Dispensary, as a general rule, unless some fair reason is given for coming from another district and not calling upon the dispensary within that district, it is practically more systematic and orderly to refer the patient to the dispensary of his own district.

"We discourage non-residents coming into our district, and we think they should call upon the dispensary of their own localities.

"We consider it, moreover, statistically of much importance that the district system be preserved."

The Eastern Dispensary, Demilt Dispensary, Northwestern Dispensary, and Northeastern Dispensary all concur.

Question II., answers. New York Dispensary—"In answer to the second question, we consider it important that an investigation of the kind suggested should always be made.

"The fact that a very large number of persons perfectly able to pay for medical advice and medicines fraudulently seek aid at the dispensary as if they were of the class of necessitous poor, is too well established to be questioned for a moment.

"This dispensary for a long time has recognized this fact, and has attempted to correct the above by making an examination of each new and unknown applicant, to learn his or her actual means and necessities.

"It is proposed now to extend this system of investigation. The inquiries suggested are put by the examining physician, who should have printed tables upon which the answers are to be entered. The inquiries are: 1, name and age; 2, residence; 3, occupation; 4, monthly rent paid; 5, amount of daily, weekly, or monthly earnings; 6, whether there are other means of subsistence than those earnings, and, if so, what? 7, if liable for the support of others? 8, if out of employment, for how long? 9, if a woman, single, married, or widow, and if having children how many? 10, other questions arising from the answers to the previous questions. If the application is made for a child, the same questions as to parent, or one *in loco parentis*."

Similar answers were given regarding all the other questions by all the dispensaries addressed, and the committee sums up with the following recommendations:

"1. That no necessity exists for more general dispensaries in districts already occupied.

"2. That a close attention to the rule of geographical limits is most necessary.

"3. That only necessitous poor should receive treatment in the dispensaries, and that those who can pay something would benefit themselves as well as the institution by being required to pay a small sum on the basis either of attendance or of medicine.

"4. That, in general, the means of applicants can more easily be determined by the amount of rent or board paid than by any other method, but that care should be taken to exclude no one from the benefits of the institution through inability to pay.

"5. That it is desirable to establish a uniform definition as to the value of the term, dispensary patient.

"6. That it is desirable that the several dispensaries should, so far as is practicable, act in harmony in respect to the subjects here discussed, and that by occasional conferences, for which provision has been made originally by most of the dispensaries, many of the minor abuses to which medical charities are peculiarly exposed would be most conveniently remedied."

The *Medical Review of Reviews*, in an editorial of November 25, 1897, says:

"It is evident from the perusal of our exchanges that the interest in the question of the proper administration of charitable institutions for the cure of the

sick is not confined to New York City. We do not wish to discuss the question here, further than to correct a possible misapprehension of the aims and purposes of medical men in this city. . . .

"At the annual meeting of the Medical Society of the County of New York, . . . those who did not support a certain ticket were credited with being hostile to the desired reform. This view of the situation is erroneous and misleading. We aver that no class of physicians is more anxious to have unworthy applicants excluded from dispensaries and hospitals than are the physicians and surgeons belonging to the staffs of such institutions. . . . The only real divergence of opinion is regarding the best means of correcting the existing conditions. There are many questions which cannot be remedied by legislation, and if success is to be secured in this instance any proposed measure must be very carefully considered, and so drawn as to avoid any appearance of what we have heretofore termed 'the trades unions idea.' In other words, any measure to be submitted to the legislature must meet the views of the public as well as of the medical profession, and must be evidently for the public welfare. The vested rights of incorporated institutions must also be respected, otherwise opposition from them is liable to prevent all legislation on the subject."

It is quite true that many abuses cannot be remedied by legislation. It is also true that none are likely to be without legislation, as was true twenty years ago when the dispensaries were quite willing to correct the abuses, and, as will be seen by the answers, quite willing to have all cases investigated. Regarding the bill of last winter, there may be evidence of public support in the fact that it passed the legislature without a dissenting vote in either branch.

Corporate rights were not intended to be attacked in that measure. The bill which is now prepared and will be introduced at the coming session of the legislature certainly attacks the rights of no incorporations or persons. It simply aims to have all dispensaries licensed by the State board of charities, and gives the State board power to make rules whereby investigations can be made by a central bureau, or in such manner as it may deem best. That this bill does not affect some dispensaries as they would like is evidenced by the fact that one or two would now like to go out of business, but cannot do so under existing laws, and this bill will probably not help them.

It would seem now after twenty years that the editorial remarks in the MEDICAL RECORD of August 17, 1878, are again appropriate:

"Substantial progress has been made, however, in the direction of better understanding among the different leading dispensaries in the city. There is evidently a disposition to act in harmony in respect to the subjects discussed, and a promise that many of the abuses referable to any lax management of the institutions will be duly corrected."

That the abuses were not corrected at that time seems to have been solely due to the fact that there was no legislation. By united effort we hope now to remedy that defect. W. WASHBURN, M.D.

[illegible]

Tuberculosis.—Although the human race continues to sicken and die of pulmonary tuberculosis, it is the consentaneous opinion of the medical profession, as shown by reports gathered from all parts of the world, that we have in creosote a remedy capable of arresting a certain percentage of cases. This drug should, therefore, be administered carefully, systematically, and continuously in every case of consumption, provided it is well tolerated and there is no contraindication or idiosyncrasy as to its action.—CROOK.

Therapeutic Hints.

Sciatica.—

℞ Sodii glycero-phosphat. . . . . 5 gm.
Aq. dest. . . . . 20 "
M. S. Inject ½ c.c. deeply into muscles near the nerve.

It is not painful, and recent cases soon recover, while inveterate instances are improved.—BILLARD.

Treatment of Cardiac Complications of Arterio-Sclerosis.—To stimulate diuresis and increase the elimination of lime compounds by the kidneys:

℞ Sodium bicarbonate . . . . . 10 gm.
Neutralize with:
Lactic acid . . . . . q.s.
Then add:
Lactic acid,
Syrup . . . . . āā 10 gm.
Distilled water . . . . . 180 gm.
M. To be taken in the twenty-four hours.

—RUMPF.

Whooping-Cough.—

℞ Tr. bellad. . . . . 10 gm.
Phenacetin . . . . . 5 "
Spirit. frumenti. . . . . 15 "
Ext. fol. castaneæ. . . . . 60 "
S. For infants of one year, ten drops. For children of ten years, one drachm every two to six hours.

—LANCASTER.

Acute Pneumonia.—

℞ Beechwood creosote . . . . . 25 gm.
Tincture of gentian. . . . . 50 "
M. S. From 25 to 150 drops a day in wine.

—CASATI.

To Stimulate Involution of the Uterus in Cases of Anæmia.—

℞ Tr. gentian. comp.,
Tr. cinchonæ comp.,
Tr. cardamom. comp. . . . . āā ℥ iss.
M. S. Two drachms before meals.

—DAVIS.

Rickets with Anæmia.—

℞ Syr. ferri iodidi . . . . . gtt. iij.–xxiv.
Aq. dest. . . . . q.s. ad ℥ iij.
M. S. One drachm every four or five hours.

—HARE.

Uræmic Convulsions.—Blood letting, except in the feeble. A vastly greater amount of poisonous material can be discharged in this way than by the slower elimination through the emunctories.—WILSON.

Tuberculosis.—

℞ Creosote (beechwood). . . . . ℥ i.
Tr. gentian. . . . . ℥ i.
Alcohol. . . . . ℥ i.
Vin. albi. . . . . q.s. ad ℥ iv.
M. S. One drachm in wine three times a day.

—SMITH.

Catarrhal Pneumonia.—

℞ Ammon. carb. . . . . gr. xxiv.
Syr. tulu. . . . . ℥ vi.
Spt. vini gal. . . . . ℥ iij.
Syr. senegæ. . . . . ℥ iiiss.
Syr. acaciæ. . . . . q.s. ad ℥ iij.
M. S. Teaspoonful every two hours for a child of two or three years.

—GOODHART *and* STARR.

Chronic Rheumatism.—

℞ Liq. potass. arsen. . . . . ℥ ii.
Potass. iodid. . . . . ℥ ij.
Syr. simp. . . . . ℥ iii.
M. S. ℥ i. t.i.d. p.c. in water.

—DA COSTA.

Amygdalitis.—

℞ Sodii benzoat. . . . . ℥ i. to ℥ iv
Glycerini,
Flix. calisayæ . . . . . āā ℥ i.
M. S. Teaspoonful every hour or two.

—STEVENS.

Simple Angina.—

℞ Potass. chlorat. ..... ℥ iss.
Potass. bromid ..... ʒ ss.
Ext. belladonnæ ..... gr. iv.
Syr. limonis ..... ʒ i.
Syrupi ..... q.s. ad ℥ iv.
M. S. Teaspoonful thrice daily.

—Pepper.

Acute Gastritis.—

℞ Vin. ipecac.,
Tr. nuc. vom. ..... āā ℥ i.
M. S. Two drops in water every two hours.

—Pepper.

Neuralgia.—

℞ Acid. osmic. ..... 0.10 cgm.
Aq. dest. ..... 6 gm.
Glycerini ..... 4 gm.
M. S. Inject 0.01 cgm.

—Chapiro.

Eczema of the External Auditory Canal.—

℞ Acid. phos. dil ..... ℥ iv.
Tr. ferri perchlor. ..... ℥ ij.
Syr. limonis ..... ℥ iij.
M. S. Teaspoonful in wineglass of water after meals.

Aloin comp. pills, one-tenth grain, night and morning, to relieve the constipation.

℞ Acid. carbol. pur. ..... gr. xx.
Ung. zinc. ox. benz. ..... ℥ i.
M. S. Apply.

Begin the local treatment by cleansing the ears with this ointment spread upon cotton on the applicator, then make a free application of the same ointment. No fluids, soap, or water must be used, as they nearly always prove deleterious.—Dr. J. W. May, *Kansas Medical Journal*, May 1st.

Mental Depression in Diseases of the Pelvic Organs.—

℞ Strych. sulph. ..... gr. $\frac{1}{30}$.
Quininæ sulph. ..... gr. iss.
Ext. hyoscyami ..... gr. iss.
Ferri redacti ..... gr. i.
M. For one pill. S. One pill three times a day.

—Tally.

Malnutrition in Infants.—

℞ Ol. olivæ ..... ʒ ij.
Glycerini ..... ℥ i.
Vitelli ovi ..... No. i.
M. et ft. emulsio et adde
Creosoti ..... ♏ xvi.

—*Practitioner.*

Pertussis.—

℞ Infusion of belladonna leaves ..... gr. viij.
Distilled water ..... ʒ v.
Antipyrin ..... gr. xv.
Syrup of gooseberry ..... ℥ i.
M. S. A teaspoonful every two hours for a child of five years.

As a rule, there may be given, for each year of the child's age, gr. viii. of belladonna leaves in infusion and the double dose of antipyrin.—Eschler.

For Colic in Infants.—

℞ Tr. lobeliæ ..... gtt. i.
Aquæ ..... ℥ i.
S. ʒ i. at a dose; give warm and repeat p.r.n.

Holton.

Chronic Nephritis.—Ferran advises a vegetable and fish diet: 1. When the quantity of urine passed exceeds eight hundred grams in the twenty-four hours. 2. When the urea and the density are somewhat augmented, or, at least, normal. 3. When there is increase of phosphates and phosphoric acid. 4. When the quantity of albumin is not exaggerated or subject to great variation. He desires to note that, in order to estimate the real quantity of albumins, he would recommend not to use Esbach's apparatus, owing to the fact that its reaction at the same time precipitates mucin, peptone, etc., which are causes of error. 5. When there is not great abundance of granular casts. 6. When the general condition is satisfactory.

Typhoid Fever.—For an adult:

℞ Salol. ..... ʒ ij. 2.60
Thymol. ..... ʒ ij. 2.60
Tablets of cupric arsenite (āā gr. 0.01) ..... No. xx.
Papoid ..... ʒ ij. 2.60
Guaiacol carbonate ..... ʒ ss. 2
Pulv. saponis ..... gr. v. 0.33
M. ft. caps. No. xx. S. One every four hours with milk.

For children:

℞ Beta-naphthol, dissolved in heated oil ..... gr. xxiv. 1.56
Ol. amygdal. dulcis, dis. in heated oil ..... ʒ ss. 16
Ol. cassiæ ..... ♏ i. 0.06
Pulv. acaciæ ..... q.s.
Glycerini ..... ʒ ss. 16
Aquæ ..... q.s. ad ʒ iij. 96
M. ft. emulsio. S. One teaspoonful every four hours with milk for a three-year-old child.

—E. Viko.

Sciatica.—

℞ Nitroglycerin, alcoholic solution (one per cent.). ℥ ss.
Tinct. capsici ..... ʒ iss.
Aq. menth. pip ..... ʒ iij.
M. S. Five drops thrice daily in a tablespoonful of water for the first three days, and ten drops thrice daily on the following days.

—Troussevitch.

Hemorrhoids.—

Plumb. acet. ..... gr. i.
Mass. hydrarg. ..... gr. ss.
Ol. theobrom ..... q. s.
Ft. suppos. i. Introduce one morning and evening.

—Orville Horwitz.

Vaginal Wash.—

℞ Powdered alum,
Powdered boric acid,
Powdered borax ..... āā ʒ iv.
Hydrastine sulph ..... gr. xl.
Carbolic acid,
Oil of cinnamon ..... āā ♏ lxxx.
Triturate. S. Use one teaspoonful in a pint of hot water for vaginal injection once daily.

—W. B. House.

Seasickness.—

℞ Chloroform,
Tincture of nux vomica ..... āā gtt. x.
Compound tincture of lavender ..... ʒ i.
Water ..... ʒ x.
M. A teaspoonful to be taken every hour until the vomiting and nausea have subsided, care being taken to shake the bottle each time before the dose is poured out.

—Barbas.

Scarlatina.—Begin treatment with the administration of calomel; then give throughout the disease:

℞ Chloral ..... gr. xxx.
Syr. lactucarii,
Aquæ ..... āā ʒ ss.–ʒ i.
M. S. Teaspoonful in ice water every two or three hours.

Complete narcotism should never be attained.—Wilson.

Dilatation of the Perineum in Labor.—The hands are rendered aseptic and an ointment of vaseline with six per cent. each of cocaine and antipyrin is applied to the perineum, vagina, and os uteri. This guards the perineum against rupture, hastens delivery, and greatly diminishes its pain.—Cormolos.

Pruritus Vulvæ.—Free the genitalia from hair, wash out the vaginal canal with sublimate solution so that no pathological material remains, and then cover the diseased spots on the vulva with three or five per cent. carbol-vaseline. The procedure must be repeated every three or four days until a good result is secured.—Ruge.

New Instruments.

AN IMPROVED CENTRIFUGE.

By WILLIAM H. MAY, M.D.,

The accompanying illustration is of a new and simple centrifuge made by Bausch & Lomb, of Rochester, N. Y. It has single gear of hardened bronze, which gives a speed of three thousand revolutions a minute with ease. The horizontal arm carries two aluminium shields, made to contain two taper glass tubes for urine or sputum work. Tubes are made graduated or plain. Milk tubes for obtaining percentage of cream are also supplied. Its simplicity, compactness, and low price should make it a useful help to the general practitioner.

A RETINOSCOPIC TRIAL CASE

By FRANK ALLPORT, M.D.,

Several appliances for retinoscopy have been devised, but none seem thoroughly satisfactory and practical. The ordinary test lens is, after all, the most serviceable. Surgeons, however, do not enjoy transporting their test cases or an assortment of lenses into the dark room for frequent retinoscopic examinations. I have, therefore, requested E. B. Meyrowitz to make for me a small compact case of lenses, to be left permanently in the dark room. The lenses consist of a series of spherical concave and convex lenses, ranging in strength from 0.2 D. to 8 D., which is a sufficient variety. Stronger lenses when occasionally necessary can be made by combinations. A double trial frame accompanies the case, which also contains a solid disc. To permit easy handling in the dark, the lenses are placed farther apart than in the ordinary trial case.

A NEW TRACHEAL TUBE.[1]

By WALTER L. CHAPPELL, M.D.,

The tube which I present to you this evening originated in my endeavors to secure a more perfect instrument for use in children suffering from recurrent papillomata of the larynx. The difficulty experienced in permanently eradicating these growths is familiar to you all. One of the most successful methods of treatment in my practice has been the wearing of a tracheotomy tube for at least a year. This treatment preserves the voice and gives much better ultimate results, but has some drawbacks. The length of the ordinary tracheal tube heretofore employed causes considerable irritation, such as cough, expectoration, and the formation of exuberant granulation tissue around the opening and on the mucous membrane of the trachea. Furthermore, it is considered by some to be responsible for many cases of pneumonia and bronchitis occurring within a short period of the primary tracheotomy. In the writer's experience the chief objection to the old tube is the recurring bronchitis and broncho-pneumonia to which the wearer is liable during cold weather, and in fact at every atmospheric change. The air entering the lungs without first passing through the heat chambers of the upper air tract keeps the tracheal and bronchial mucous membrane in a subacute catarrhal state, which readily passes to bronchitis. I have in three cases employed with entire satisfaction the tube shown this evening; in two under my personal supervision, and in a third case, at Springfield, Mass., under the direction of Dr. F. E. Hopkins. The parts of the tube or obturator are as follows: An outer cannula which extends from the cutaneous surface to the anterior wall of the trachea. Of course this distance varies in different cases, but in a child from three to four years old is about half an inch. A plate or collar surrounds the tube at a level with and rests on the skin. The external end of this cannula is furnished with a male thread. The internal cannula is tube and wire-cage work. The tubular part ceases at the anterior wall of the trachea, and the cage work passes through into the interior of the trachea. The length of the cage work will depend on the antero-posterior diameter of the trachea. The inner end of the cannula is tipped with a smooth saucer-like cap, which presents a smooth surface to the mucous membrane of the posterior wall of the trachea. It is important that this tip shall not press on the posterior tracheal wall. This is prevented by having the external end of the interna cannula fitted with a movable nut, cut with a female thread, to fit the male thread of the outer cannula. By this device the inner cannula can be lengthened or shortened an eighth of an inch or more, to suit the diameter of the trachea and to relieve any pressure which may exist. The importance of this arrangement is well illustrated in the case which was under Dr. Hopkins' direction. The tube was inserted and worn with perfect comfort for some days, when the tip of the inner cage began to impinge on the posterior wall of the trachea, and created considerable irritation. The inner tube was then temporarily withdrawn and a cork placed in the outer cannula. This, being very short, gradually slipped out and allowed the tracheal wound to close. It is evident that, if the pressure on the trachea cannot be

[1] Read before the laryngological section of the New York Academy of Medicine November, 1897.

relieved by the movable nut, the only safe procedure is to remove the entire tube and introduce an ordinary tube, until the necessary alterations can be made. The accurate adjustment required in each case necessitates a new tube, or one specially fitted for each person. This is some objection, but cases of recurrent papillomata are so important that the end justifies the trouble. A small plug accompanies the tube, and may be used as occasion demands. It appears to me that the following advantages may be claimed for this tube:

1st. It is easily and safely retained by passing a piece of perforated adhesive plaster over the head of the cannula as far as the plate, and then pressing it against the skin.

2d. Being short and light, it produces little irritation.

3d. The open cage work in the trachea allows the patient to breathe through the tracheal opening or larynx at will. This is of great advantage, as has already been mentioned.

4th. With the plug inserted, the patient is able to speak more clearly.

5th. Should there be much laryngo-tracheal catarrh, the mucus can readily be coughed into the pharynx.

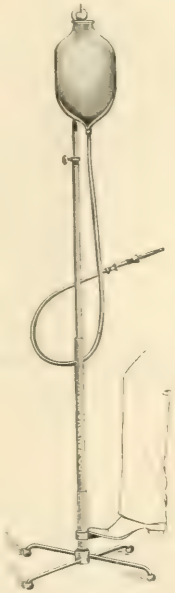
Regarding the use of this tube in other than the cases mentioned, I have had little experience. The large tube which is shown this evening has just been made for a case of epithelioma of the larynx, but has not yet been tried. It seems reasonable to predict that this tube will also prove serviceable in cases of diphtheria necessitating tracheotomy.

AN ADJUSTABLE IRRIGATING STAND WITH PEDAL CUTOFF.

By CEPHAS L. BARD, M.D.,

This device is presented to the notice of the profession with an assurance, based upon a thorough trial, that it will materially contribute to the fulfilment of some of the requirements of an aseptic operation.

Although applicable, at least its cutoff, to the stationary irrigators of the hospital, it is especially designed for use in connection with a fountain syringe, preferably of large capacity. It is manufactured in two forms—the detachable and non-detachable. The former, placed in a case one yard in length, is easily carried to the home of a patient by the surgeon, in his hand or carriage. Its component parts being placed in position, it will sustain at varying heights a four-quart fountain syringe, filled with water and weighing eight pounds. Aside from the immense advantage of its cutoff, about to be described, its use obviates the necessity of suspending the syringe bag from a bedpost, chandelier, or nail driven in the wall, and as it is conveyable it is unnecessary to carry the patient to the syringe, as hitherto has been the case. The non-detachable form is intended for hospital use. By reference to the accompanying cuts, it will be seen that the tubing of the syringe passes through an opening of the hollow standard, and, when the instrument is not in use, is compressed between the convex top of a slide rod, situated interiorly and actuated by a coiled spring at its base, and the concave face of a block placed directly above the opening. Pressure of a foot on a pedal, connected with the lower end of the slide rod, removes the compression of the tubing, and a stream is obtained which continues as long as the pressure is exerted. When it is desirable to have the flow without the constant foot pressure, the pedal by a sidewise motion of the foot may be pushed and fixed in a slot provided for that purpose. The pedal cutoff enables the operator to obtain and to arrest a flow of liquid instantly, with but slight exertion on his part, and as the nozzle, which should preferably be of glass, is the only portion of the apparatus touched by his hand, the danger of infection from that form of contact is absolutely removed. An additional security may be provided by slipping a sterilized muslin sleeve, a foot or more in length, over the delivery end of the tubing. The various hand-controlled cutoffs are without doubt frequently sources of infection, and



their disuse will contribute to the safety of the patient. The control of the cutoff is so complete and so easily effected that the services of an assistant in managing the flow are seldom required, a feature which will be fully appreciated by those operating ouside of the walls of a hospital. With it, for example, a curettage and minor gynæcological operations can be performed by a surgeon whose only assistant is the anæsthetizer. Its convenience will be fully appreciated by the nurse when douches are required in septic cases in the lying-in room.

It is made by Charles Truax, Greene & Co., of Chicago, to whom I am indebted for their faithful adherence to my ideas in its construction.

Uretero-Ureteral Anastomosis. — 1. Uretero-ureteral anastomosis is a perfectly feasible procedure. 2. Uretero-ureteral anastomosis, whenever possible, is far preferable to any other form of ureteral grafting, to nephrectomy, and to ligation of the ureter. 3. It should be done preferably by lateral implantation, or by oblique end-to-end anastomosis, though the transverse end-to-end or the simple end-to-end method may be safely employed. 4. The constrictions of the calibre of the ureter do not usually follow attempts at suturing in closure of complete transverse section of the duct. 5. Nephrectomy for transverse injuries of the ureter, *per se*, is an unjustifiable operation. 6. Simple ligation of the ureter, to produce extinction of the functions of the kidney, is too uncertain to justify its practice. 7. Drainage is not necessary if the wound be perfectly closed and the tissues throughout are aseptic. — J. Wesley Bovee.

A PAIR OF RETRACTORS.

BY RAMON GUITÉRAS, M.D.

NEW YORK.

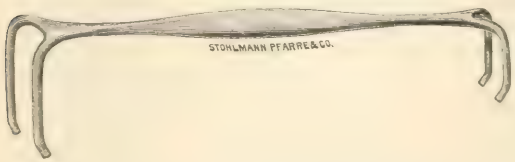
In all of the various operations in surgery, no instruments are more important to the surgeon than is a pair of well-formed and well-devised retractors. Different surgeons have their own favorite instruments which they are in the habit of using, and which through constant use they are led to consider the best.

In teaching operative surgery to post-graduate students, however, most of whom have had considerable practice in operative work, one cannot help being led by their various comments to see certain defects in the instruments in common use.

Retractors have always seemed to come in for a fair share of criticism, and the different varieties have been from time to time so commented upon that I decided to try to devise a pair which could be used in any operation with comparative satisfaction by the general practitioner.

The results of my observations have guided me in devising the pair of retractors which I am about to describe.

Description.—The shaft is seven inches long with a pair of prongs at either end. These sets of prongs



vary in length. The larger pair is two inches long, and they are separated by a distance of three-quarters of an inch from one another. This allows the tissues to bulge out between them, and thus help to hold it in position. At the end of the prongs there is a slight curve inward. This prevents the deeper tissues from slipping, and consequently holds them with a firmer grasp. This larger pair is especially useful in abdominal cases for retracting the abdominal parietes, and is also valuable in operations on deep tissues elsewhere, as in the gluteal region, the thighs, back, etc.

The smaller pair of prongs on the other extremity is just one-half the length of the pair described. They are separated only by half an inch. Their shape is the same, and they also have the ends turned inward, to prevent the tissue from slipping. This smaller end of the retractors is of service in operating where the tissues are not so thick, as on those about the neck and the extremities.

Another advantage that these retractors have over many others is that the assistant's hand is not obliged to grasp the shaft, and thus be directly in the way of the operator, either by partly covering the field of operation or by throwing a shadow over it; for, if one end of the retractor is in the wound, the other end can be supported by the finger of one hand, in such a way that the hand itself is eight or ten inches away from the field of operation.

West [illegible] Street.

The Strawberry Tongue in Scarlet Fever.—The tongue which is characteristic of scarlet fever, and is pathognomonic when it is present, is the bright-red, clean tongue with prominent papillæ, and not the tongue which presents a white coat with the swollen red papillæ protruding, which occurs earlier in the course of the disease.—FUSSELL.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 11, 1897:

	Cases.	Deaths.
Tuberculosis	220	97
Typhoid fever	56	14
Scarlet fever	169	16
Measles	302	17
Diphtheria	161	17
Laryngeal diphtheria (croup)	8	7
Chicken-pox	32	0

Hall Caine Jollied.—Under the title of "Hospital Happenings," Mr. Hall Caine's "Christian," with its unfair lies in regard to hospital management, has been jollied capitally in a little paper called the *Guyoscope*. The celebrated ball at St. Bartimæus' is sketched as follows: "Last Tuesday the first students' ball of the season took place in the operating-theatre of St. Bartimæus Hospital. The arrangements generally reflected great credit on the members of the dance committee, who by the way were distinguished by wearing Murphy's buttonholes in their coats. The floor had been carefully scrubbed with softsoap and lysol, and would have made an admirable dancing-surface had there been room to dance. As it was, the majority of the guests preferred to take advantage of the magnificent promenade afforded by the spacious corridors of the hospital. . . . The proceedings opened with a solo clog dance on the operating-table by Sir William McCormac, who was attired in mackintosh and sterilized overall. Next, in response to vociferous appeals, the matron of the hospital obliged with a serpentine dance, all first years' students having been previously anæsthetized. After these two superb displays of Terpsichorean skill a general move was made for the supper room, a delightfully airy apartment used on more prosaic occasions as a dissecting-room. Boyish students might be seen pledging their laughing-eyed partners in foaming beakers of hyd. perchlor. (1 in 2,000, 1897), while their staider elders fortified themselves with modest injections of brandy and strychnine. We can personally testify to the exhilarating qualities of the formalin cup, which was much appreciated by those privileged to partake. If a criticism can be permitted us, we venture to think that the conduct of the surgical-instrument keeper in boiling the spoons between every course was somewhat unnecessary and certainly inconvenient." As *The Lancet* remarks, this is excellent fooling, and is the right way to treat a book at once so stupid and pretentious as "The Christian."

Jonathan Hutchinson on the Medicinal Employment of Coffee.—In his *Archives of Surgery*, Jonathan Hutchinson says: "I have often been in the habit of prescribing coffee as a medicine in certain states of great debility. It appears to me to be a remedy quite unique in its usefulness in sustaining the nervous energy in certain cases. Apart from its general usefulness, I have found it of especial service after operations when anæsthetics had been used and in a state of exhaustion when alcohol had been pushed and a condition of semicoma followed. In these latter cases I have sometimes prescribed it as an enema when the patient could not swallow, and with the best effects. Its value as an antidote to opium is of course well known. Tea and coffee seem to me to be much alike

in many respects, but I would give preference to the latter, as to its sustaining powers. It would, I think, be a great advantage to our working classes and a great help toward a further development of social sobriety, if coffee were to come into greatly increased use, and if the ability to make it well could be acquired."

The Sleep Problem.—As town life extends and intellect is aroused, the problem will be more and more that of too little, not of too much sleep. Perfect or nearly perfect health is of course the first condition of sound sleep. But scarcely any one is quite healthy, and so we must aid the sleepless to acquire that which is lacking. The one great thing to do is to fatigue the attention; not only to tire out the body but also the active mind; to quiet the vasomotor centre and so drive the congested blood from the brain. Quiet and regular habits, a certain monotony of light evening occupation, will tend in this direction, while a great variety of evening engagements is generally fatal to the victim of insomnia. It is unwise to go to bed on either an empty or very full stomach; a slight meal before rest is the wise course. A hot bath the last thing, taken under the following conditions, is perhaps the very best aid to sleep: As recommended by Eccles and others, the bath should be taken in a room with a temperature of 65° to 70° F. The patient should stand with his head over the edge of the tub, douching head and face with water at 100° F. The cooling of the body by the air and the hot sponging of the head first send blood to the brain, dilating its vessels. Then the entire body, except the head, is immersed in a bath at 98° F., rapidly raised to 105° or 110° F.; in a few minutes the bath is left, and the body wrapped in blankets, which absorb the moisture, and with the least possible exertion the patient gets into his night clothes and to bed with a warm bottle to his feet and perhaps a little warm liquid food.—*Spectator.*

The Relation between Chorea and Scarlet Fever.—Priestley (*British Medical Journal*, September 25, 1897, p. 805) relates that during the years 1894, 1895, and 1896, among eighty-three hundred and sixty cases of scarlet fever under treatment at the Northeastern Hospital of the metropolitan asylums board, thirteen cases of chorea were observed. Five of these cases presented rheumatic manifestations, which in each instance immediately preceded or presented themselves simultaneously with the chorea. These symptoms set in considerably later than the usual period at which the articular complications of scarlet fever occur—that is, after the first week. Of the thirteen cases cardiac murmurs developed in seven. The average interval between the onset of the scarlet fever and that of the chorea was over thirty-five days.

Sudden Hyperpyrexia in a Fatal Case of Delirium Tremens.—Bell (*Lancet*, October 2, 1897, p. 859) reports the case of a man, forty-seven years old, who came under observation suffering from the effects of excessive indulgence in alcohol. Vomiting was the chief complaint, and was relieved by the administration of an effervescing mixture with fifteen minims of tincture of opium every three hours. Improvement gradually set in, but in the course of two days symptoms of delirium made their appearance. The temperature, which had previously been normal, rose to 105° F., following a "fit," with loss of consciousness. The man was placed at once in an ice sheet, with an ice bag to his head, and potassium bromide and antipyrin were given every three hours. The temperature, however, rose rapidly to 109.8° F., and death ensued. On post-mortem examination the brain and meninges were much congested, but no hemorrhage could be found. The heart was fatty and the liver was enlarged with commencing cirrhosis, but no other lesions could be made out.

"Catching Cold" as a Cause of Disease.—From a general survey of the subject, Chalmonski (*Deutsches Archiv für klinische Medicin*, B. 59, H. 1, 2, p. 140) concludes that "catching cold," in the ordinary sense, is not a causative factor in disease, playing in general a very subordinate part as an etiologic agency. In inflammatory diseases it may act as only a predisposing factor. "Catching cold" depends upon the activity of thermic agents which are usually not to be avoided; that is, upon the influence of slight degrees of cold. The degree of cutaneous reaction to the given thermic stimulus is an indication whether the individual may take cold under certain conditions. The degree of disposition to "catching cold" forms no constant peculiarity of the given individual. Individuals of advanced age, febrile patients, and those suffering from renal disease appear to be more disposed than others to disease resulting from "catching cold." Between the predisposition to such disease upon the one hand, and the nutritive state and the temperature sensibility upon the other, there is no connection. The prophylactic measures directed in general toward "catching cold" are not only attended by a directly opposite result, but they further expose the organism to far greater danger than is to be anticipated from disease resulting from "catching cold." Protection against such disease may be secured by increasing the reactive capability to thermic irritants by means of suitable exercises.

Croup.—Croup is asthenic localized inflammation, whose causation is connected always with some exposure to cold, wet, etc.; it is never epidemic. Diphtheria is a general disease, usually epidemic and asthenic in type; the local inflammation in it is secondary to the constitutional affection. In croup the false membrane is a solidifying exudation upon the surface of the mucous membrane; in diphtheria it involves its substance also. Croup is not attended by albuminuria or followed by paralysis; both occur not infrequently with diphtheria.—HARTSHORN.

Anæmic versus Organic Heart Murmurs.—An anæmic is distinguished from an organic murmur by its blowing character; by always accompanying the first sound of the heart; by being audible in several of the arteries at the same time; by not being constantly present, occasionally disappearing when the circulation is tranquil and returning when it is accelerated; by the presence of the general signs of anæmia; by the absence of the physical or general signs of organic disease of the heart; by entirely disappearing under treatment calculated to relieve the anæmic state of the system.—W. H. HARRIS, *Journal of Medicine and Science*, June, 1897.

A Prescription.—The appellate court of Indiana holds that a prescription is to be defined as meaning "a statement usually written of the medicine or remedies to be used by a patient and the manner of using them." The following writing was not admitted as falling under this head: "B. W. Tilford, druggist, Martinsville, Ind. R. Spt. frumenti, qt. 1. For medical use. Date, November 10, 1895. B. W. Tilford, M.D." We are forced to admit that, if intended for an infant and to be given at one dose, some unfortunate complication might have arisen.

Specialism.—The following declarations concerning the mutual obligations of the specialist and the physician have been formulated by the Medical Society of the Ninth District of Vienna: 1. The specialist is a physician who renounces practice in all branches of

medicine with the exception of a well-defined part. 2. The specialist should undertake no treatment without an understanding with the physician of the patient or of his family. 3. The physician should be informed of the diagnosis made, and his advice should be sought for important interventions. 4. If it is not possible for the physician to direct the treatment to be followed, the specialist should permit him to take part in it to the extent of his aptitude. 5. The patient cannot be sent by the specialist to a third physician unless with the consent of the physician in ordinary.

Acute Pleurisy a Form of Tuberculosis. — That cases of acute pleurisy are often tuberculous has been known for some time; that they are almost invariably so seems now to be proved. Attention was first drawn to the fact by continental writers. In 1890 Dr. Alfred G. Barrs read a paper before the Leeds Medico-Chirurgical Society. As the result of carefully compiled statistics he confirmed the conclusion of Mayor, that "the majority of cases of simple idiopathic pleurisy or pleurisy from exposure to cold conceal or reveal a tuberculous process. In 1893, however, Dr. William Osler in his Shattuck lecture concluded that two-thirds of the cases were non-tuberculous. In 1895 Eichhorst published the results of injecting the fluid obtained from cases of serous pleurisy into the peritoneal cavity of guinea-pigs. Two-thirds of the animals developed tuberculosis. The *Boston Medical and Surgical Journal* of August 5, 1897, contains an important paper by Dr. George G. Sears. On injecting tuberculin in ten cases of acute pleurisy, he obtained a reaction—rise of temperature—in nine. He limited the reaction to this by using a small dose—one milligram, increased if necessary. His results are nearly identical with those cited by Netter, who obtained a reaction in thirteen out of fifteen cases. The question is of practical importance. Though the prognosis as regards the attack is good, there remains the tendency to develop other and more serious forms of tuberculosis.—*Lancet.*

The Onion and the Teacher.—In Topeka a schoolmistress forbade the eating of onions by the scholars, whereupon all the scholars took to the diet and the teacher was overpowered and yielded. In onion there is strength.

Early Diagnosis of Pregnancy.—Rinman observed in two cases, as an early symptom of pregnancy, slender cords radiating from the nipple, which he believes to have been the hypertrophic acini of the glands. Secretion was not yet present. This observation has been confirmed by others.

Male Nurses in England seem to have difficulty in obtaining adequate instruction. It is said that no general hospital gives a course of training for males.

In Doubt.—Having read the directions on the box, "Take one every two hours till gone," she sent in haste to the prescriber, to know if he meant her or the pills.

The Wolffian Body in its Relations to Gynæcology. H. Peters (*Lindemann's klinische Vorträge*, October, 1897), after a complete and interesting survey of the embryology of the parts involved, considers the pathological conditions of the female ratus referable to the Wolffian body and duct. These he divides as follows: 1. Cysts of parovarium. A not rare form of thin-walled intraligamentous cyst, seldom larger than a child's head and characterized by lying close to the unchanged ovaries. The contents are usually of a thin, colorless, sometimes slightly opalescent fluid. Their growth is very slow and they are prone to spontaneous rupture and subsequent refilling. When small they give little trouble and do not require any interference, but larger ones may require extirpation. 2. Cysts of ligamentum latum and referable to the paroöphoron. These are usually small and thin walled, holding a colorless limpid fluid, and are of little clinical importance, as they seldom attain a size to call for interference. 3. Cystomyomata, embracing adenomyomata of the lateral and posterior wall of the uterus and similar growths of the broad ligaments and tubes. These are of importance as producing chlorosis, dysmenorrhœa, menorrhagia, sterility, inflammatory processes in the peritoneum, or vesical and peristaltic disturbance, etc. Their prognosis is more serious than that of most myomata, and total extirpation is indicated. The author concludes that the Wolffian body and its duct play an important part in gynæcology, although it is to the future we must look for a clear distinction between its domain and that of the Müllerian duct.

How to Use Knockout Drops.—The following directions were found on a sneak thief recently arrested: "The one most dangerous is any one affected with heart trouble, as it takes immediate action on the heart, causing the heart to beat so rapidly as to finally kill. Fifteen drops of aromatic spirits of ammonia given immediately with a hypo. injection of atropine will always counteract the effect. When you are about to administer, take fifteen drops in a small homœopathic vial, hold in palm of hand, drawing the cork with thumb and forefinger of same hand, reach over the patient's glass, calling his attention, and—why, 'Bang!' he is yours. This is about as explicit as is possible without demonstration. You know the penalty to be caught with it in your possession." The "drops" are composed, it is said, of chloral.

Health Reports.—The following statistics concerning yellow fever, cholera, plague, and small-pox have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended December 11, 1897:

A UNIQUE CASE OF COMPLETE REMOVAL OF THE STOMACH—SUCCESSFUL ŒSOPHAGO-ENTEROSTOMY—RECOVERY.

BY CARL SCHLATTER, M.D.,

PRIVAT-DOCENT AT THE UNIVERSITY OF ZURICH, AND ASSISTANT AT THE SURGICAL CLINIC.

Introductory Remarks by Dr. Edmund Charles Wendt, of New York.—During my recent stay at Zurich, Switzerland, I was enabled, through the kindly courtesy of my friend, Dr. Carl Schlatter, personally to study the remarkable and unique case about to be described. At the date of the present writing, December 9, 1897, over three months since the operation of total ablation of the stomach, the woman is still under observation at the county hospital; but she is to all intents and purposes a well woman, and does her full share of the daily work of the ward. On the date of my first visit I found her in a very cheerful frame of mind, and quite loquacious. She is already beginning to realize the interest and importance attaching to her case, as she has had medical visitors from many quarters of the globe. The lay press of all Europe has got wind of this extraordinary instance of a "live woman without a stomach." Garbled reports of her case have appeared in London, in Paris, in Berlin, in Vienna, and, perhaps, by this time, in New York. It seems to me that the readers of the RECORD may well be congratulated upon receiving a detailed account of this case from the pen of the operating surgeon himself. It is only fair to mention, however, that, at the request of the editor of *The Lancet*, an abstract of this case has just been forwarded by Dr. Schlatter to London.[1] I take this opportunity of expressing my sincere thanks to the young *savant*, who so cordially assisted me in my efforts to obtain for the American profession an authentic account of the case. On my several examinations of the patient I was particularly struck by her ruddy complexion, fair general appearance, clean, moist tongue, absence of all fœtor ex ore, moderately full and vigorous pulse, and general alacrity. She informed me that her appetite was good, but that she was never allowed to feel really hungry. She relished her meals and her taste was unimpaired. The bowels acted naturally once in twenty-four hours. Her sleep was normal. She complained of no pain.

In a word, save for some degree of emaciation, a noticeably dry skin, and her abdominal cicatrix, the woman at present[2] offers no apparent departure from ordinary average health. How long can she survive the non-existence of gastric digestion? Who can tell? Clinical observation sometimes rudely disturbs our most cherished school-taught physiological dogmas.

Total Ablation of the Human Stomach not Hitherto Done.—It is quite well known that gastrectomy so called is not tantamount to total extirpation of the stomach. The recorded cases of gastric excision are, without exception, instances of partial (chiefly pyloric) removal of the stomach. At the hands of some surgeons, it is true, very large portions of this organ of digestion have been removed, even in ordinary cases of pylorectomy. Some recent operations of this kind have resulted successfully. I recall one case in particular, which occurred at the surgical clinic of Professor Krönlein, of Zurich, which necessitated the almost complete removal of the stomach. This case[1] was one of gastrectomy for colloid cancer. Twenty-two centimetres were removed from the greater curvature and thirteen from the lesser. The patient recovered. Hacker and Maydl have also lately recorded similar cases.

Quite recently several cases of so-called total extirpation of the stomach have also been recorded. But as a careful study of the published reports shows that some small part of the stomach was always allowed to remain, these cases cannot be, strictly speaking, considered as instances of complete removal of the organ.[2]

Writing in the *Deutsche medicinische Wochenschrift*, Langenbuch, in 1894, referred to two cases of alleged total excision of the stomach. The patients were women, respectively fifty-eight and fifty-six years of age. But proof is wanting that no part of the stomach was left behind. One of the patients died six days after the operation. Moreover, in the successful case, while fully seven-eighths of the stomach was excised, the remaining cuff-like parts of the pyloric and cardiac portions proved sufficiently large to admit being joined together by suture.

Professor Schuchardt, of Stettin, removed the major part of the stomach in a case of cancer in 1895. In advance of a detailed account of his case, soon to be published, he has kindly sent me the following particulars of this interesting observation: "The patient, whose stomach was almost completely excised in 1895, has just died after an interval of two and a half years of apparent perfect health. The autopsy showed that from the cardiac stump a new stomachal pouch, with a capacity of over one pint, had been formed. It was in consequence of the new formation of this post-operative stomach that the patient, who at first was unable to take more than very small quantities of nourishment, was finally able to partake of ordinary meals in the ordinary way."

Animals have Survived Complete Destruction of the Stomach.—It has been known for some time that dogs are able to survive the artificial obliteration of the stomach and the loss of its functions. This interesting physiological observation was made as long ago as 1878, by Czerny and his pupils, Scriba and Kaiser.[3] Indeed the so-called "Czerny dog" survived the oper-

[1] It is also proper to state that in preparing the English version of Dr. Schlatter's case I have relied on reprints of an address delivered by him before the Swiss Medical Congress, and that this address has just appeared in the current issue of the Correspondenzblatt für Schweizer Aerzte.

[2] The date of my [illegible] December [illegible]

[1] Krönlein: "Chirur. Erfahrungen über das Magencarcinom." Beiträge zur klin. Chirurgie, vol. xv., p. 326.

[2] Ewald read a paper at the International Medical Congress at Moscow entitled "Erfahrungen über Magenchirurgie, vornehmlich bei malignen Geschwülsten" (Berliner klin. Wochenschrift, 1897, No. 37, p. 798). The case of ablation there referred to was also incomplete, about one inch of the cardiac end not having been excised. The patient died three days after the operation from hemorrhage.

[3] F. Kaiser. "Beiträge zu den Operationen am Magen," in Czerny's Beiträge zur operat. Chirurgie, 1878.

ation of gastric excision for five years, and was then killed for purposes of anatomical study. But even in the case of this "celebrated" animal, the post-mortem showed that a small part of the cardiac end of the stomach had not been excised. And it was further seen that a small sac had gradually been formed from this remnant, and had fulfilled gastric functions.

In 1893 Drs. Pachon and Carvallo published the results of their observations in connection with a gastrectomized dog, which was still alive and gaining weight five months after the operation. This dog frequently vomited, and the ejected matter showed the presence of organic acids.

Last year Monari[1] published a further contribution to this subject. The dog in his case, however, lost weight steadily after excision of the stomach. Nevertheless Dr. Filippi failed to discover any noteworthy alterations in the physiological functions of this animal, more particularly in regard to metabolism. One year later a post-mortem showed that the lower extremity of the œsophagus, as well as the stomachal extremity of the duodenum, had become distended, although not yet to any very considerable degree.

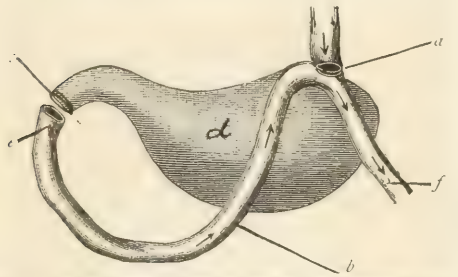

FIG. 1.—Showing Preparatory Steps for Operation. *a*, Œsophageal cut; *b*, duodenum; *c*, duodenal slit; *d*, stomach; *e*, slit closed by suture; *f*, jejunum.

FIRST COMPLETE EXCISION OF THE STOMACH IN A HUMAN BEING.

History of the Case by Carl Schlatter, M.D., the Operator.—The personal observation forming the subject of this paper, relates to a woman, fifty-six years old. In her case I completely excised the stomach, even beyond its cardiac extremity, and then restored the continuity of the alimentary canal by stitching a loop of small intestine into the lower end of the œsophagus, *i.e.*, œsophago-enterostomy.

History of the Present Case.—Anna Landis, aged fifty-six years, silk weaver by occupation, claims that cancer is hereditary in her family. As a child she recalls having had frequent attacks of abdominal pain. According to her own notion these attacks were due to the poor quality of the food at the orphan asylum where she was brought up. Later on she often complained of severe pains in the stomach, accompanied or followed by vomiting. She never saw bloody admixtures in the ejected matter, but large quantities of bile often came up. Medical treatment had never afforded her any relief. Ever since the spring of 1897 the attacks of vomiting were of daily occurrence. Progressive emaciation also ensued. Several weeks before her admission to the hospital a physician told her that she had a tumor of the stomach.

I first saw the patient at the surgical polyclinic on August 26, 1897. An inspection of the abdomen revealed a marked bulging between the left hypochondriac region and the umbilicus. The abdominal parietes were flabby, and palpation easily revealed an oval mass of hard consistency in the region of the stomach. The tumor was freely movable. Its size was about that of two fists. Very marked emaciation was found. The patient was unable to retain any kind of nourishment. She clamored for relief by surgical interference.

She was admitted to my wards for further careful observation. I did not feel confident that gastrectomy, or even gastro-enterostomy, could be successfully performed, on account of the large size of the tumor.

The patient continued to reject almost everything, including fluids. The iodide reaction of her saliva (after exhibition of iodide of potassium) required forty-seven minutes for its first appearance. The chemical examination of her gastric secretion showed no trace of free hydrochloric acid. An operation was, therefore, no longer delayed.

Description of the Operation.—On September 6, 1897, acting for Professor Krönlein, I performed laparotomy under morphine-ether anæsthesia and with strict antisepsis—incision in the median line, extending from the ensiform process to the umbilicus. As I had anticipated, the entire stomach presented itself in the shape of a hard mass extending from the cardiac to the pyloric extremity. Strangely enough, the tumor was freely movable. It was readily lifted out of the peritoneal cavity. Three rather soft lymph nodes were found at the greater curvature near the pylorus. The stomach being diseased *in toto*, a gastro-enterostomy was impossible. I at once decided to attempt to excise the entire organ, or take recourse in a jejunostomy. I first freed the stomach from all its attachments at the greater and lesser curvature, having previously shut off the general cavity of the peritoneum by sterilized compresses. The omentum was incised between Péan's forceps. Silk sutures were used. The stomach was then forcibly dragged downward so as to enable me to reach the œsophagus. The left lobe of the liver had to be constantly held upward by an assistant, in order to permit me freely to manipulate within the field of operation. In this way I finally succeeded in securing the œsophagus rather high up, by means of a Wölfler clamp. A Stille forceps was next fastened closely to the cardiac end of the tumor. Then the stomach was severed directly beneath the œsophageal extremity. As the œsophageal incision appeared somewhat oblique, I proceeded to place a small occluding suture at the gastric wound. The same steps were now repeated at the pyloric end of the stomach.

I next mobilized the duodenum, as far as possible toward the head of the pancreas. Then, having applied a duodenal compressor, and likewise a tumor clamp, I removed the entire stomach, between the two points of compression. I also dissected out the lymphatic nodes above mentioned. The patent lumen of the duodenum was treated like the œsophageal opening with iodoform gauze. The broad bridge joining together different divisions of the alimentary canal had now been entirely removed.

I next tried to pull the duodenal opening upward toward the œsophageal cleft. It was only with considerable difficulty that the two could be made to touch. It was manifestly impossible to join them by direct suture. I, therefore, invaginated the duodenal rim, and closed the opening by a double suture. I then searched for a suitable coil of small intestine. Beginning at the duodenal-jejunal fold, I followed down the intestine for about fifteen inches. The presenting knuckle of intestine I grasped, and, pulling it over the transverse colon, I placed it against the œsophageal slit.

A piece of this intestine, about five inches in length, was secured between two Wölfler clamps. By means of sutures not going deeper than the serous coat, the intestine was then attached to the œsophageal stump. A longitudinal slit about one inch in length was then made into the bowel. Then the mucous membrane of the œsophageal end was firmly united with the intes-

[1] Beiträge zur klinischen Chirurgie, Vol. XVII, 1896, p. [illegible].

tinal mucous membrane, by a continuous circular suture. The material employed was silk. Above this, a second suture, extending through the muscular and serous coats, was introduced. A Lembert suture finally completed the stitching, which now seemed to hold.

The œsophageal and duodenal clamps were then removed, the former having remained in position for over two hours. On dropping back the organs into the abdominal cavity, the sutured portions showed marked retraction upward, toward the œsophageal part of the diaphragm. The abdominal wound was closed in the ordinary way by silk ligatures. Less than eight ounces of ether had been employed during the narcosis, which had fortunately been a very quiet one.

Pulse after the operation, 96 a minute, steady, and of fair volume.

There had been only a very slight loss of blood during the course of the operation, which, however, had lasted nearly two hours and a half.

Clinical Observations Following Removal of the Stomach.—Shortly after the operation the patient received an enema containing brandy and two eggs. Temperature in the evening, 36.4° C.

September 7th.—Two nutrient enemas containing milk, eggs, and brandy. Pulse rate has risen to 142, but in volume remains moderately good. Patient has taken per os, in the course of the afternoon, a small quantity of tea and milk, which is apparently well borne. No signs of peritonitis. Evening temperature, 37.3° C.

September 8th.—Nutrient enemas no longer retained. Claret wine in teaspoonful doses given, until half a glass has been taken. Patient complains of sudden abdominal pains, which, however, quickly subside. Evening temperature, 38.1° C.; pulse, 160, but of moderately good volume.

September 9th.—Subjective symptoms considerably improved. At intervals of two hours, very small quantities of milk, eggs, bouillon, and wine are given.

Small quantities of pepsin and muriatic acid have been tentatively added to the food. Pulse better, 146 per minute. Highest temperature, 38.1° C.

September 13th.—Dressing removed. The abdominal wound found united by primary intention without a trace of local reaction. Stitches removed. Patient allowed a little scraped meat for the first time. The first movement of the bowels since the operation took place September 10th. Since then the patient has had from two to three fluid stools daily.

Occasionally there is some regurgitation of ingested milk, but actual vomiting has not occurred.

September 16th.—Patient feeling remarkably well; temperature normal; pulse, 100; slight diarrhœa.

From now on the patient was able to take fairly large quantities of food. Mornings at 7, a cup of milk with one egg; 9:30, cup of milk with one egg. Dinner, very soft scraped meat, or a cup of thin gruel with an egg; 4 P.M., cup of milk with egg; 7:30 P.M., a cup of milk or gruel. In addition to these regular feedings, she also takes tea and Malaga wine, amounting in the course of the day to from five to seven ounces.

On September 16th, for the first time since the operation, vomiting occurred. It was preceded by nausea, apparently superinduced by the patient having witnessed a change of dressing in a neighboring surgical case. There was a good deal of retching, and about seven ounces of bilious and slightly acrid fluid were ejected.

September 26th.—Patient is allowed to have half a chicken, the last remnants of which she swallowed at 4:30. At 6:30, customary milk and egg. At 7:30, attack of vomiting with considerable retching and marked contractions of the abdominal muscles. The ejected matter amounted to about ten ounces, and consisted largely of milk and meat fibres. For some time before this attack patient had complained of a decidedly bitter taste in her mouth.

October 2d.—Another attack of vomiting. The ejected fluid measured over six ounces. It was yellowish in color and not offensive. This attack came on one hour after eating. Examination showed that undigested egg and milk had been thrown up.

October 4th.—An attack similar to the one just noted was observed.

October 8th.—Another attack of vomiting. The slimy fluid was sent to the laboratory for chemical examination. The report received stated that the reaction of the fluid was distinctly acid. This was owing to the presence of lactic acid, as no free hydrochloric acid was found. Trypsin reaction was also discovered. Bile acids and bile pigment were likewise present in appreciable quantities. It should be

Fig. 2.—Photograph of the Patient, Showing Abdominal Cicatrix. (Taken December 1, 1897, nearly two months after the operation.)

mentioned, in this connection, that the patient was no longer taking pepsin and muriatic acid.

October 11th.—Patient left her bed for the first time since the day of the operation, *i.e.*, September 6th.

November 25th.—Patient feeling quite well and able to walk about comfortably.

There was a steadily progressive increase in the weight of the patient after removal of the cancerous stomach. This is readily seen by the following:

TABLE SHOWING WEIGHT OF PATIENT AFTER OPERATION.

Date of Weighing.	Actual Weight in Grams.	Increase in Grams.
October 5th	33,600	
October 11th ..	33,750	150
October 18th ..	35,260	1,510
October 25th ..	35,500	240
October 29th	36,000	500
November 5th	36,200	200
November 19th ..	36,500	300
December 3d.....	37,500	1,000
December 9th.....	37,800	

[1] The patient was not actually weighed on the day of the operation, but the minimum increase from September 6th to October 5th has been estimated at [illegible]

Pathological Report on the Excised Stomach.—The specimen consists of a human stomach measuring twenty-eight centimetres (eleven inches) along the greater curvature, and twenty centimetres (eight inches) along the lesser. The greatest width between the curvatures amounts to ten centimetres (four inches) (see Fig. 3). The gastric cavity is so completely occupied by a neoplasm that it is difficult to force a finger in at either extremity.

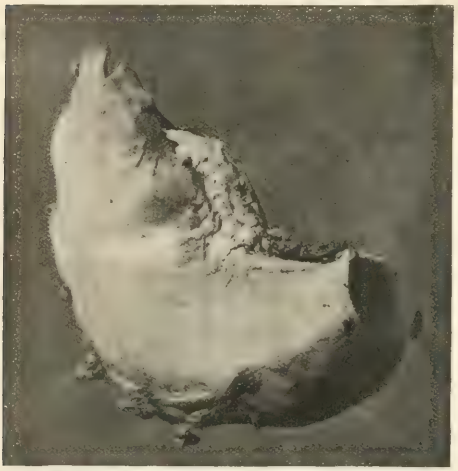

FIG. 3.—Front View of Excised Stomach. The specimen has undergone shrinkage, owing to the action of alcohol, in which it is preserved. The slits visible at the greater curvature are due to removal of specimens for microscopical examination. The œsophageal and pyloric extremities show where portions of the organ were excised *post operationem* for anatomical study.

From both the cardiac and pyloric ends, small portions were cut off and sent to the Pathological Institute of the university (see Fig. 4). Professor Ribbert made the following report on these specimens: one piece is unmistakably œsophageal in histological structure. The other specimen is just as unmistakably duodenal. Microscopical examination showed the neoplasm to consist of a small-celled alveolar glandular carcinoma. According to the microscopical report of Professor Ribbert, already alluded to, there can thus be no question that in my case the gastric excision extended into the territory of the œsophagus. Nevertheless, anatomical considerations did not make it clear to me why, during the course of the operation, it had seemed so easy, comparatively speaking, to gain access to the œsophagus. Of course it must be remembered that I made use of considerable traction downward by pulling on the stomach itself, and it was in this way that the subdiaphragmatic portion of the œsophagus became markedly elongated.

This practical demonstration in the living subject received anatomical corroboration from the prosector at the anatomical institute of the university. I was informed that it was always possible under normal conditions to elongate by traction the lower subdiaphragmatic portion of the œsophagus.

The accompanying lymph nodes were found to be non-cancerous.

Practical Anatomical Observations.—I would like in the first place to say a few words in regard to the technique of the foregoing operation. Langenbuch,[1] in connection with his recorded gastrectomies, has published the following statements: "Of course my gastrectomies did not amount to total extirpation of the stomach. And, indeed, total ablation appears to be practically impossible toward the cardiac extremity of the stomach. For the cardiac portion has, like the head of the humerus, an anatomical as well as a surgical neck. Bearing in mind this anatomical peculiarity, it seems admissible to regard my operations as instances of total exsections of the stomach. For in both cases I removed as much of the organ as was technically possible."

Now the boundary-line between the œsophagus and cardiac extremity of the stomach is clearly defined. The former is supplied with pavement epithelium; the latter shows the cylindrical variety. Personal observations and experiments on the cadaver fully confirmed this observation.

In the case of my patient it should also be borne in mind that as soon as the Wölfler clamp was removed, marked upward traction of the œsophageal stump was witnessed. Possibly the weight of the neoplasm had previously contributed its share toward dragging down the œsophagus. I cannot, therefore, accept the quoted statements of Langenbuch.

Dietary Considerations Following Removal of the Stomach.—In attempting suitably to regulate the nutrition of my patient after the operation, it became first of all necessary to bear in mind what functions had been done away with by complete ablation of the stomach. It seemed to me *a priori* possible that the patient should survive, on account of the previous practical elimination of all gastric functions, owing to the large size of the tumor. Nevertheless it became an object of my solicitude to discover means for the compensatory substitution of something new in place of the loss of the old. It is true, modern physiological research no longer vouchsafes to the stomach its old rôle as chief organ of the digestive apparatus. Nevertheless, its importance in chemical as well as in physical respects should not be underestimated. It is still a question whether the human organism can long survive the total elimination of all gastric activity.

Physiological Observations.—It is well known that, considered merely as a food reservoir, the stomach exercises a highly beneficial influence over all ingesta. Food is retained for a shorter or longer period in the stomach, according to differences in its nature. To the bowel there is thus insured a measurable degree of safety from overloading. As a corrector of widely different degrees of temperature of various kinds of food, the stomach certainly fulfils an important office. The well-known chemical and mechanical activities of

FIG. 4.—Posterior View of Excised Stomach. The photograph shows distinctly where portions of the wall of the organ were cut out at either extremity for microscopical study. The neoplasm fills out the entire cavity of the stomach.

[1] Deutsche medicinische Wochenschrift, p. 969, 1894.

the stomach, as also the disinfecting potency of its secretions, need not be specifically dwelt upon to establish the manifold importance of this organ. The bactericide action of gastric juice in cholera and other diseases need only be mentioned in passing. The capacity for absorbing certain liquids, while not so important as was formerly believed, should nevertheless also be borne in mind.'

Clinical Observations in Connection with the Obliteration of all Gastric Functions After the Operation.—There being no food receptacle after ablation of the stomach, it became obligatory to feed my patient at first with minute quantities of food, given at short intervals. The results of this method of procedure were in all respects happy ones. Quantities of food approaching ten ounces seemed to excite vomiting. So, too, cold fluids resulted in diarrhœal discharges, and may have been partly responsible for the rise in temperature, observed for some little time after the operation.

Keeping in mind the absence of mechanical function, the patient's dietary was at first a strictly fluid one. But as early as the second week after removal of the stomach, semi-solid and even solid food was allowed. It was retained and digested without discomfort. The patient having only a single tooth, mastication was of course quite imperfect, otherwise it seems to me possible that an ordinary mixed diet might have succeeded at a still earlier date.

Some weeks after the operation the patient's ordinary daily dietary was as follows: At regular intervals of from two to three hours she took milk, eggs, thin gruel or pap, tea, meat, rolls, butter, and Malaga wine. The daily quantity amounted to one quart of milk, two eggs, two to three ounces of pap or gruel, seven ounces of meat, seven ounces of oatmeal or barley water (as thick almost as gruel), one cup of tea, two rolls, and half an ounce of butter.

Personally I felt most concerned about the obliteration of all chemical activity on the part of the absent stomach. I soon perceived that adding pepsin and hydrochloric acid to the food was theoretically as inadmissible as it had been found practically valueless. The alkaline fluids of the intestine at once neutralized the acid, and rendered the pepsin inert.

Fortunately it soon became apparent that despite the absence of acid pepsin, proteids were readily assimilated in the intestinal tract.

Does Gastric Acidity Influence the Decomposition of Intestinal Contents?—This moot question received contributory elucidation by the careful study of the patient's discharges after the operation. The urine and fæces were examined every day at the chemical laboratory of the university. Products of abnormal intestinal fermentation or decomposition (skatoxyl and indoxyl) were either not at all found, or else discovered only in traces.

These observations tend to corroborate the views of v. Noorden,[2] while it negatives the opinion held by Kast and Wasbutzki. The most recent results of laboratory experiments announced from Professor Baumann's institute, viz., that hydrochloric acid inhibits intestinal decomposition, thus received no support from actual observations in the living human subject.

Does Removal of the Stomach Affect the Rapidity of Intestinal Propulsion?—Observations on this point are still being made, and at the present time I am unable to present any very definite conclusions. The patient objected to swallowing charcoal. Huckleberries were at three different times found in the passages, twenty-four hours after having been swallowed.

The Urine After the Operation.—Apart from a daily recurring diminution in the quantity of excreted chlorides, the urine of this woman has remained normal since ablation of her stomach. The daily excretion of chloride of sodium has been found to vary between the limits of 0.6 per cent. and 0.95 per cent. It should be stated in this connection, however, that, complying with the wish of the patient, her food is prepared with less salt than that of the other ward patients.

Microscopical Examination of the Fæces.—The stools were well formed, of normal consistency, and light yellow in color. The microscope showed large numbers of fat globules and fatty crystals, some undigested vegetable fibres, but no undigested animal fibres or connective tissue. Large quantities of triple phosphates were observed. The number of microorganisms was normal. Altogether repeated examinations revealed no noteworthy departure from a condition of perfect health.

Vomiting without a Stomach.—How can a person vomit without a stomach? No matter what theoretical physiological notions we may have imbibed from lectures and text-books, the woman under observation had repeated attacks of ordinary nausea, retching, and vomiting. We must needs conclude, therefore, that the rôle of the stomach (*i.e.*, its antiperistaltic efficacy) in this direction has been very much overrated. While the vomited substances showed an acid reaction, this was not due to the presence of free hydrochloric acid.

In view of the fact that the patient ejected as much as thirty ounces at one time, it seems reasonable to suppose that the remaining portion of the duodenum may have already begun to show distention sufficient to produce a sort of compensatory receptacle for food — perhaps nature's attempt in the direction of the new formation of a stomach.

In endeavoring to explain vomiting without a stomach, we should remember that the act itself is far from being a simple process. It is due to nervous action on a complex motor apparatus, consisting of pharynx, œsophagus, stomach, diaphragm, and abdominal muscles.

It is not surprising, therefore, to have witnessed in this woman an ordinary attack of bilious vomiting, superinduced by a mere psychical disturbance.

Conclusions by Dr. E. C. Wendt.—While it would be manifestly unfair to indulge in sweeping generalizations on the strength of this single case, so boldly rescued and ably described by Dr. Schlatter, it seems at least justifiable to formulate the following conclusions:

1. The human stomach is not a vital organ.
2. The digestive capacity of the human stomach has been considerably overrated.
3. The fluids and solids constituting an ordinary mixed diet are capable of complete digestion and assimilation without the aid of the human stomach.
4. A gain in the weight of the body may take place in spite of the total absence of gastric activity.
5. Typical vomiting may occur without a stomach.
6. The general health of a person need not immediately deteriorate on account of removal of the stomach.
7. The most important office of the human stomach is to act as a reservoir for the reception, preliminary preparation, and propulsion of food and fluids. It also fulfils a useful purpose in regulating the temperature of swallowed solids and liquids.
8. The chemical functions of the human stomach may be completely and satisfactorily performed by the other divisions of the alimentary canal.

[illegible] I have thought it advisable, in order to curtail the length of this communication, considerably to abbreviate this portion of Dr. Schlatter's interesting remarks.—E. C. W.

[2] V. Noorden: "Lehrbuch der Pathologie des Stoffwechsels," p. 245, [illegible]

9. Gastric juice is hostile to the development of many micro-organisms.

10. The free acid of normal gastric secretions has no power to arrest putrefactive changes in the intestinal tract. Its antiseptic and bactericide potency has been overestimated.

COMMON SENSE IN THE TREATMENT OF DIGESTIVE DISORDERS.[1]

BY DAVID INGLIS, M.D.,

DETROIT,

PROFESSOR OF MENTAL AND NERVOUS DISEASES, DETROIT COLLEGE OF MEDICINE.

THE writer feels that an apology is due for the initial claim implied in the title—that of assuming to have common sense. So uncommon does common sense appear to be, that to claim it seems presumptuous.

Let me then interpret my meaning by saying that the effort of this article is simply to recall, for our fresh contemplation, certain physiological laws, familiar to us all—the object of this being to prevent us from being led away by certain enthusiasms.

There have arisen in these times certain enthusiasts in the mechanical treatment of gastric and intestinal disorders. These form one detachment only of the great army of medical mechanics. From the top of the head to the sole of the foot, no organ is safe from the man who proposes to effect dynamic changes by mechanical means. Let us grant that there are many things which can be accomplished by mechanical means, but let us keep in mind the fact that the constant play of function in every organ of the body is the result of dynamic activities which are wholly out of reach of mechanical assistance.

Keeping this in mind, what judgment shall we form of the present attempt to explain dyspeptic disorders by a mechanical theory, that of dilatation of the stomach, and their treatment by mechanical means, the stomach tube? As a basis, let us take some statements from a recent author, Bouchard, whose book, "Auto-Intoxication," has had a considerable circulation. Bouchard first states that "dyspepsia is accompanied by dilatation of the stomach in seven-eighths of the cases" (p. 161). Again he says: "In a ward in a hospital, out of ten patients taken at random, you will find three with dilatation." Once more: "Dilatation of the stomach may exist without inducing anomalous sensations, without dyspeptic or gastralgic symptoms, in two-thirds of the cases. It is a disease which does not announce itself; we know that it passes unperceived."

Put into concentrated form, these statements mean that of all dyspeptic patients seven-eighths have dilatation of the stomach, but that this very considerable number by no means represents the total; on the contrary, for every dilated stomach which causes dyspepsia, there are two others which do not. And finally, about one-third of our hospital patients of all sorts have dilated stomachs.

Here is a great field for mechanical therapeutics, but we have by no means exhausted its importance, for Bouchard goes on to enumerate the symptoms of dilated stomach, a disease which, he naively says, "does not announce itself"—"it passes unperceived." The symptoms of dilatation of the stomach are as follows, according to this writer: Pulmonary phthisis, chlorosis, eructations, sensation of heaviness at epigastrium, sensation of heat at epigastrium, pyrosis, regurgitations, catarrh of stomach, ulcerative gastritis, false cancers, inflammation of large intestine, membranous enteritis, hepatic congestion, jaundice, ectopia of right kidney (fourteen times out of one hundred), feeling of morning depression, painful circle around the head, headache, uneasy disposition, sensibility to cold, insomnia, vertigo, obscuration of sight, hæmiopia, diplopia, weakness of the right internal muscle of the eye, hallucinations of sight, dropsy of the limbs, contracture of the extremities of the hands, transitory aphasia, fatal syncope, sensation as if two or three fingers were dead, palpitation, flushing of the face two or three hours after meals, false angina pectoris, nocturnal perspirations, bilateral intercostal neuralgia, ezcema (thirteen per one hundred), pityriasis versicolor, urticaria, acne in young girls, catch cold easily, cough habitually, bronchial mucous secretion, recurrent bronchitis, dyspnœic respiration, recurring coryza, morning sneezing, albuminuria (seventeen per one hundred), peptonuria, loss of physical energy, loss of moral energy, emaciation, lax obesity with pallor, abundant deposits of urates, increase in acidity of urine, phlebitis, purpura (two or three per one hundred), joint nodes (twenty-five times in one hundred cases), rachitis, osteomalacia, coma.

It seems odd, to say the least, that a disease possessed of such remarkable disruptive powers should, in two-thirds of the cases, fail to announce itself. But nothing staggers our enthusiast, for he goes on to say: "I have asked myself the query, whether people who in appearance are not ill, but still have the physical signs of dilatation of the stomach, are truly healthy?"

Gentlemen, you may say that this is ridiculous. No; it is serious, for Bouchard represents the extreme of a class of enthusiasts who are looking for dilated stomachs and finding them, and who when they find them honestly believe that the first thing to do is to cure that dilatation. To this end there are multitudes of people who are having their stomachs washed out day after day for weeks and months; they are being electrified and massaged; they are being fed as if the digestion in the stomach went on as it would in a crock on a warm shelf.

It is worth while to look at dilatation of the stomach from another point of view, and here I quote our enthusiast for the last time. He says: "While very frequent in the sick, it is relatively uncommon in the healthy."

Unconsciously he gives the key to the whole matter. The stomach is subject to all sorts of variations in size in perfectly healthy people. Its muscular walls may at one time keep well contracted when it is empty, or at another time they may relax. We may form an excellent idea of the varying conditions at different times in the same individual, by recalling the contracted or relaxed scrotum. The scrotum, which is habitually exceedingly lax, still retains the power of firm contraction; as a rule, so does the stomach.

Dilatation of the stomach can be easily produced. Leaving altogether to one side these cases in which pyloric obstruction, however produced, is the efficient cause, let us note that the gases liberated by fermentation of undigested foods cause but a slight pressure; they form much as the bubbles in yeast, yet, gentle as is the internal pressure, the walls of the stomach easily yield. It is only when a sufficient nervous impulse starts a contraction that we so much as become conscious that the stomach is full of gas.

The dilatation of the stomach is mainly a matter of lack of nervous stimulus to set up peristalsis. Now we see why, "while very frequent in the sick, it is relatively uncommon in the healthy." The sick, in the usual course of things, have a lowered nervous tone: they have dilated stomachs for precisely the same reason that they are constipated, and the latter disorder is probably quite as dangerous as the former.

We can, indeed, set up an arbitrary standard for the

[1] Read before the Detroit Medical and Library Association.

size of a normal stomach, but in reality there is no such standard. It is the old story of the displaced uterus—either there is no fixed normal for the uterus, or a very large percentage of women demonstrate the fact that an abnormal position of the uterus is a matter of absolutely no importance. So with the stomach: if we set up an arbitrary standard, then it is again true that deviations from that standard constantly occur without harm to the individual.

A diagnosis then of dilatation of the stomach is arbitrary, and when made does not, taken alone, demand any treatment at all. Because a man has a dilated stomach is not of itself reason for using either the stomach tube, electricity, a limited dietary, or drugs. We are not even certain that he may have a dilated stomach next week. Something more is needed—there must be other indications for treatment, and the other symptoms which accompany dilatation of the stomach are by no means to be looked upon as the results of the dilatation. Bouchard simply makes himself ridiculous when he enumerates the long list of symptoms of dilatation of the stomach. The symptoms he gives occurred in people whose stomachs happened to exceed his standard of size. Being otherwise in poor health, they also had dilated stomachs; in most of the cases they were probably constipated.

As regards the use of the stomach tube, the great majority of dilated stomachs need no stomach tube. Get the sick well of their other sicknesses, and their dilatation will disappear. I suspect that if those other people with dilated stomachs, who obstinately persist in appearing to be well, would cultivate a little invigorating training for their general muscular apparatus, they too would get rid of their dilated stomachs without a stomach tube or anything else. It ought never to be forgotten that the stomach tube is a purely mechanical device, and that the functions of the stomach, while partly mechanical, are mainly the result of dynamic changes. The stomach tube will wash off a lot of stringy mucus, will clear out a lot of fermenting, irritating material; the abnormal irritation of lavage will stimulate muscular contraction, but the real difficulty lies back of all this. To say nothing of the annoyance of the procedure, the steady continuance of lavage sets up an entirely unphysiological habit in the stomach.

Enthusiasts, led on very naturally by the exceedingly brilliant results obtained in some cases, are in danger of forgetting that the real problem is to re-establish that normal action of secreting cells, muscular fibre, and nerves which characterizes a stomach which knows no stomach tube. They are in danger of overlooking other affections, as happened when a patient had his stomach washed out for several months and a rigid and debilitating diet kept up, while he was suffering from the gastric crises of locomotor ataxia.

It is also sometimes forgotten that a patient can drink a lot of salt water or borated water by the ordinary use of his œsophagus, and vomiting can be induced without running a tube into the stomach.

There is a field for the stomach tube. Within its limits the careful use of the stomach tube is capable of rendering services so valuable that it can fairly be claimed as one of the greatest advances in practical medicine. In cases of pyloric obstruction with retention of stomach contents and fermentation changes, lavage is capable of affording very great relief, even when the nature of the pyloric obstruction makes cure impossible. The stomach tube has greatly aided in the diagnosis of gastric affections. Lastly, in cases in which, without actual pyloric obstruction, the above-mentioned fermentative changes are going on; in cases of chronic catarrh of the stomach, however caused, lavage is again a valuable aid. There may be dilatation of the stomach in these cases, often is, but it is the ability of the stomach to effect complete digestion and obtain the normal rest of an empty stomach which decides the need of lavage—not the mere size of its walls.

In these cases the stomach tube does its good by its action on the mucous membrane rather than upon the muscular coat. In cases of complete atony, lavage and electricity are unquestionably of much value. Even in such cases these measures ought to be regarded as makeshifts, until by measures directed to the nervous system something of the normal nervous stimulus can be re-established.

Let us now take up another matter, that of "enteroptosis." We discover that things drop down. There was once a wave of enthusiasm over "falling of the womb." Every gynæcologist of any real note had a pessary named after him. I am not certain, but I think gynæcologists are rather shy of having their names printed on the pessary box nowadays.

The stomach drops down; the colon does; the kidneys slip out. Fortunately or unfortunately, pessaries cannot be invented for these; but abdominal supporters can be used, and massage and electricity come in play. What are the facts? Inasmuch as the stomach is to all intents and purposes merely a dilated piece of intestine through which foods go by peristaltic movements, it really makes very little difference whether the pyloric end points west or south. As for the intestines, nature has planned for the greatest possible mobility. We used to think that the appendix had a local habitation as well as a name. We now know that the appendix claims pretty much the whole right half of the belly, and even strays across the line.

Suppose the colon does drop down. Why, if an adult were found with a sigmoid flexure which started at the ribs, dipped down to the pubis, and wound back to the neighborhood of the left kidney, that would be a frightful drop; but young infants get along nicely with that sort of sigmoid flexure.

Unless the canal is obstructed by the displacement or an actual obstruction to the normal blood supply ensues, the precise position of stomach or bowels is of little importance. The same thing is mainly true of displaced kidney; occasionally a displaced kidney causes pain and at times reflex nervous troubles, but pretty generally a displaced kidney "does not announce itself," and the patient would be all right if the doctor were not too careful a diagnostician.

I suspect that it is not the displacement of the viscera which is the important matter, but the relaxation of the abdominal walls, which takes away the normal support for the diaphragm. When the diaphragm is itself dragged upon in its regular respiratory effort, the matter may be important, for the whole respiratory and circulatory mechanism is likely to be disturbed.

To afford support until such time as the abdominal walls can be restored to normal vigor, a proper abdominal bandage is important.

Still more valuable is the use of electricity and massage. It is not enough to support the abdominal walls; it is necessary to bring back muscular tone. But not less important is it to set up an increase in the nervous vigor by the use of such drugs as strychnine, or such measures as increase the entire nutritive activity.

Finally, a word in regard to diet. It is undoubtedly true that the idea of a test meal is logically sound, but here again there are unhappy limitations. I grant that it is feasible to give a test meal and from the examination of the stomach contents safely to state the relative abundance of lactic or hydrochloric acids, but the range of information to be gathered in this way is very limited. There are probably not to exceed ten men in Michigan whose training would enable

them to make an exact analysis of the stomach contents. The time and labor involved make such an analysis necessarily very expensive, and it is of course entirely out of the question to have such an analysis done for the various dyspeptics. The test-meal analysis is then simply a rough test of limited extent. Even in the matter of stomach acidity the result of the test is not always of certain application. There are certain individuals who go through life with habitual hyperacidity, and who are adjusted to degrees of hyperacidity which would be very damaging to the average person.

Before leaving this subject of examination of the stomach contents, I wish, in parenthesis, to call your attention to a matter of grave moment. I refer to the examination of the stomach contents by the coroner or county physician. There occur many cases in which the coroner makes a post-mortem and has the stomach contents analyzed. In some instances very grave questions of a criminal nature depend upon the result of this analysis. It is worth careful consideration to decide whether the average coroner or county physician has the very great chemical skill required to make such an analysis as ought to be made. Failure to detect poisons would let a murderer easily go free. How many county physicians could so securely demonstrate the presence of a fatal dose of poison as to warrant the condemnation of a murderer? How many analyses of the stomach contents are paid for by the State or counties?

To recur to the matter of diet. The test meal having a limited range, we need to be careful lest we regulate the patient's diet too much by theory, too little by practical results. The dietetic treatment of diabetes is very important, truly, yet I am thoroughly satisfied that not a few diabetics are brought to an early death by a too sudden change and too rigid adherence to a diet whose principle is correct enough in theory.

So with dyspeptics: we need to remember that it is the patient we are treating, not his disease. The advance in the study of digestive disorders does not absolve us from remembering and practising what we have learned in other ways and in older times.

41 State Street.

Colono-Enteric Irrigation in the Treatment of Intestinal Obstruction.—Dr. Pynchon (*Chicago Medical Recorder*, December, 1896) urges that in all cases of intestinal obstruction distensive enemata of from ten to twenty or more pints of water be employed. His clinical observation, together with a study of literature pertaining to the conditions of acute bowel obstruction, lead to these conclusions: Copious enemata promptly and persistently employed are indicated in the early stages of acute intestinal obstruction. The patient must be anæsthetized and suspended in a position of inversion. The water should be as hot as can be safely used, and there should be available no less than three gallons. A rectal tip must be used which will positively control the escape of water from the rectum, and no long colonic tube is required. No air must be allowed to enter the gut and the water pressure must be constant and not intermittent; the earlier method of alternately filling the gut as far as possible and then allowing it to empty itself is not approved. While the pressure must not be allowed to weaken, the onward flow of water can be made to alternate with forcible abdominal massage. The fall of water may be varied from fifteen to thirty feet, according to the age of the patient and the stage of the trouble, providing a lesser fall, of, say, six feet, in alternation with massage is not successful.

SOME QUESTIONS OFTEN ASKED ABOUT DRINKING-WATER, AND THEIR ANSWERS.

By B. C. LOVELAND, M.D.,

Clifton Springs, N. Y.

In the routine of a doctor's life a great portion of his time is taken up in answering questions, and sometimes it requires much patience and the exercise of the greatest tact and ingenuity to give answers which will either satisfy the patient's curiosity or convince him of the wisdom of the order that may be the subject of his inquiries. In the present day, when the practice of medicine has become so far removed from the old-time practice of "physic" and the physician has to depend on his knowledge of physiological law, and the thoroughness with which he enforces obedience to physiological law among his patients marks his degree of success, the questions elicited by the regulations he may impose may be of great importance, for the patient to-day is a rare one who will go ahead and unquestioningly obey the advice of the physician, and who will not, like the proverbial boy, always have his mouth set for "Why?" In trying to induce my patients to drink the amount of water, nine or ten glasses a day, regarded as a physiological necessity by the medical profession, I have been met with a host of questions, mostly raised as objections, some samples of which, with their answers, will comprise this paper, and my hope is that they will help some one who is trying to secure obedience to this part of nature's requirement.

"Will not water make me fat?" It is a well-known fact that most people dread becoming unduly fat, and this question is a very common one. The answer is yes and no. Water will make you fat if it increases your ability to assimilate food, if by drinking more water you are enabled to take into the system more of the food that you eat. In no other way will it make you fat. There is evidently no fat in water. It will not make you fat if your digestion is perfect already, and you do not eat a great abundance of such foods as produce fat. In fact I have often seen people reduce fat, who needed to do so, by drinking a large quantity of water and using a properly regulated diet.

"Will not so much water strain my kidneys?" is another question which is asked almost as frequently as the preceding one. The answer is simple. Water does not strain the kidneys any more than more help in building a house strains the workmen. The excretion of the kidneys is twofold—water and certain other materials which are the result of the wear on the tissues. This water is the vehicle in which are carried in solution all the ingredients of waste tissue which the system is trying to get rid of. The flow of water through the kidneys to the bladder simply furnishes a current in which to carry off the dissolved detritus; therefore the drinking of a physiological amount of water cannot strain the kidneys.

"If water will thin my blood when it is too thick, will it not make it too thin if I continue to drink so much?" This question is often asked by patients of plethoric habit and lithæmic tendencies whom I am trying to impress with the necessity of getting the system thoroughly washed out, and the question seems a logical one. The answer, however, makes it plain. The blood craves a certain percentage of water; that certain percentage it will take up and hold, providing a continual supply is being added, but with the blood pressure and circulation automatically regulated by the mechanism which is called the sympathetic nervous system, and with the ready outlet afforded by the kidneys, all water taken in above the amount required to keep the blood at its normal proportion of fluid and solid is passed on, through, and out, and does its duty simply by washing the system of its impurities. It is

often the case that water given in free quantity to a patient suffering from anæmia so assists the digestion that it will help thicken the blood, while in a person of plethoric habit the action is quite the reverse.

"Will drinking a large amount of water continuously produce catarrh of the bowels or bladder?" This question has been seriously asked by patients, from the fact that a person unaccustomed to drinking the physiological amount of water finds the first effect of drinking such an amount to be the necessity of a frequent evacuation of the bladder, and not infrequently it may also cause looseness of the bowels. But we find by experience as well as by logic that the use of such an amount of water as is a physiological necessity does not produce catarrh of the bladder, but rather helps such troubles by so diluting the urine as to render it less irritating, thus giving nature a chance to cure the trouble. And not infrequently catarrh of the bowels may be due to an insufficient elimination by the kidneys, in which case the bowels attempt to take up work left undone by the kidneys, and the expression of this effort is indicated by the catarrh, which will be relieved by drinking a sufficiently large quantity of water.

"Will not drinking water make me perspire unduly?" Drinking water up to the physiological amount in the case of a person who has not perspired for years, owing to a lack of sufficient water, may temporarily produce excessive perspiration, such perspiration lasting only, like the flushing of the kidneys, until the system has been relieved of the poisons that can be excreted in that way. In other words, free action of the kidneys and skin, following the use of a normal amount of water when the patient has been for a long time deprived of that amount, is only nature's expression of joy at having once received her deserts.

"Will not cold water chill my stomach and thereby cause harm?" The reply to this question is, unduly cold water might; ice water, for instance; but water at a temperature making it pleasant to drink, say from 45° to 60° F., will not chill the stomach. An illustration from nature is shown in the fact that nearly all our springs are cold, very few hot. Most of the water we drink should be cold; hot water should be used for other purposes than to supply the system with the necessary fluid.

But my patient says: "Water drinking gives me gas on the stomach, and if it does so I should not drink it, should I?" Why not? There is no gas in water. If gas appears in the stomach, or is noticed in the stomach after drinking water, it simply shows that gas was there before, and the water, displacing the gas, causes more or less eructation, and is frequently one of the best methods to relieve the stomach of gas.

"Doctor, if water turns sour on my stomach, I suppose it is a sign that water disagrees with me, isn't it?" Water does not turn sour in any one's stomach. It may bring to the knowledge of the patient the fact that an acid condition exists in the stomach, in the same way that it brings to him the knowledge of the presence of gas in the stomach, but it will not produce acidity any more than it will produce gas, and if acid is in the stomach it was there before, and instead of making it worse water will manifestly make it better. The more water we put into vinegar the less acid it is, and the more water we put into the stomach the less concentrated will be the acid, be it fermentation acid or not. Consequently the answer to this question is that it is not a sign that water disagrees with a person, but a sign that something else needs attention, and the water is not contraindicated.

"Will not water, drunk at meals, retard digestion?" In a majority of cases the answer will be, No. It does not retard digestion unless it is drunk in undue quantity, and used as a means of washing the food down, to save the labor of properly masticating it and mixing it with saliva. A moderate quantity of water in most cases aids digestion by increasing the fluidity of the contents of the stomach, and thereby favoring the admixture of the gastric fluid with the food.

"Shall I drink hot or cold water?" The use of hot water is valuable when there is pain or distress in the stomach, and should be then favored. In the case of a delicate, sensitive stomach, when the patient cannot be induced to drink the necessary amount of cold water it is often easier to get him to take it hot, but for general purposes most of the water drunk should be used cold, or cool, for the tonic effect of cool water on the stomach is greater than that of hot, just as its tonic effect on the skin is greater.

"I should not drink water, should I, unless I am thirsty?" The reply to this question is that the lack of thirst in a grown person is no indication of his need of water or not. A child is always thirsty, and we would be thirsty at proper intervals, so that the appetite would be a guide, if we did not from preoccupation or some other cause which makes us inattentive to the impulse neglect it, until we find it often absent altogether. When such a condition exists, manifestly thirst is not to be regarded as an indication of the patient's need, for many patients say they are never thirsty.

Several of the questions asked and answered in this paper owe their origin to theories that have come down from our ancestors in medicine, and perhaps from our grandmothers, who were not our ancestors in medicine. The absurdity of the old-time notions about water may be well illustrated by the following extract, on the medical view of the use of water about three centuries ago, taken from *The Hospital:*

"It needed a very bold man to resist the medical testimony of three centuries ago against water-drinking. Few writers can be found to say a good word for it. One or two only are concerned to maintain that 'when begun in early life it may be pretty freely drunk with impunity,' and they quote the curious instance given by Sir Thomas Elyot in his 'Castle of Health,' 1541, of the Cornishmen: 'Many of the poorer sort, which never, or very seldom, drink any other drink, be, notwithstanding, strong of body and like and live well until they be of great age.'

"Thomas Cogan, the medical schoolmaster of Manchester fame, confessed in his 'Haven of Health,' 1589, designed for the use of students, that he knew some who drank cold water at night or fasting in the morning without hurt; and Dr. James Hart, writing about fifty years later, could even claim among his acquaintance 'some honorable and worshipful ladies who drink little other drink, and yet enjoy more perfect health than most of them that drink of the strongest.' The phenomenon was undeniable, but the natural inference was none the less to be resisted.

"Sir Thomas Elyot himself is very certain, in spite of the Cornishmen, that 'there be in water causes of divers diseases, as of swelling of the spleen and liver.' He complains oddly also that 'it flitteth and swimmeth,' and concludes that 'to young men, and them that be of hot complexions it doeth less harm, and sometimes it profiteth, but to them that are feeble, old, and melancholy, it is not convenient.'

"'Water is not wholesome cool by itself for an Englishman,' was the version of Andrew Borde—monk, physician, bishop, ambassador, and writer on sanitation—as the result of a life's experience. And to quote the 'Englishman's Doctor':

> "'Are enemies to health and good digestion,
> Both water and small beer, we make no question.'

"But the most formal indictment against water is that of Venner, who, writing in 1622, ponderously pro-

nounces: "To dwellers in cold countries, it doth very greatly deject their appetites, destroy the natural heat, and overthrow the strength of the stomach, and consequently, confounding the concoction, is the cause of crudities, fluctuations, and windiness in the body.'"

CASES OF LONG-RETAINED PLACENTA FOLLOWING ABORTION.

BY NEWMAN T. B. NOBLES, M.D.,

CLEVELAND, OHIO,

DEMONSTRATOR OF ANATOMY AND ASSISTANT DEMONSTRATOR OF SURGERY, CLEVELAND MEDICAL COLLEGE.

THE following cases are important as illustrating how long the placenta may be retained *in utero*, after escape of the fœtus, unless they are removed by early manual interference.

CASE I.—Mrs. D—— was pregnant for the second time, four months advanced. She concluded not to have this child, so after repeated efforts with drugs she at last succeeded in puncturing the membranes. After several hours the fœtus was expelled, followed a few hours later by a substance which the attending physician pronounced placenta, but which, in the light of subsequent events, must have been coagulated blood. At any rate the hemorrhage continued, with the exception of short intervals, for twenty-two days, unabated in spite of all efforts to control it. Ice was employed both externally and internally, the vagina tamponed; ergotin, iron, and quinine were given in massive doses, whiskey and brandy without restriction—all with no effect so far as the hemorrhage was concerned.

Finally, after the woman had flowed for over three weeks, the physician resigned the case or was discharged, and I was sent for. I found the patient in a deplorable condition, presenting all the classical symptoms of alarming hemorrhage. Digital examination showed a rigid os uteri; the womb was anteflexed and much larger than normal, even after an abortion. I naturally concluded that the placenta had not been expelled. The friends and relatives insisted that both they and the former attendant had seen the afterbirth three weeks before, and I must be mistaken. I was determined to be satisfied as to the true condition, and so the cervix was dilated, and then digital examination revealed a soft, fleshy mass in the uterine cavity, firmly attached to its internal parietes. With curette and placental forceps a well-organized placenta was removed. The membrane was normal in appearance and fortunately non-putrescent. The after-treatment consisted of antiseptic intra-uterine injections, nourishing diet, and the usual drugs. A good recovery was the result, though the convalescence was tedious.

CASE II. — Mrs. K ——, aged twenty-eight, the mother of four children, suffered from abortion caused by fright on March 14, 1896. The fœtus escaped during the night, and the next day the woman went about the house as though nothing had occurred. After a few weeks an offensive sanguineous and excoriating discharge appeared. Soon her health began to fail and she became greatly emaciated. During this time a physician attended her. On June 29th, over three months after the abortion, she was suddenly taken with a most profuse hemorrhage. It stopped for forty hours and then began afresh. Finally, twenty days after the flooding and one hundred and twenty-five days subsequent to the abortion, I was called in. As in the previous case, the uterus was enlarged and anteflexed, and the os was so contracted that it was next to impossible to introduce a sound. After it had been dilated sufficiently a large, soft, fleshy mass attached to the uterine walls was discovered. This when removed proved to be a well-organized placenta. After the operation the patient went into profound shock and for hours her life was despaired of. She rallied under the liberal use of stimulants and made a good recovery. A slight rise in temperature appeared forty-eight hours after the operation, but this disappeared upon intra-uterine injections of antiseptic solutions.

GANGRENE OF THE LEG FOLLOWING TYPHOID FEVER; AMPUTATION BELOW THE LINE OF DEMARCATION; RECOVERY.

BY J. Q. ALLEN, M.D.,

MONTROSE, COL.

ON September 26, 1896, I was called to see a girl, sixteen years old, living five miles in the country. She had been quite sick for some days, and I found a well-established case of typhoid fever. This ran the typical course of a severe attack for four weeks, when on October 24th indications of gangrene appeared in the left foot and leg. Just before this there was evidence of the fever having spent its force. The circulation was not good and the extremities were cold. I ordered mild stimulants and artificial heat. Several bottles were filled with hot water, wrapped in flannels, and laid alongside the legs. By some means the covering of the bottles became displaced and the hot glass came in direct contact with the skin, producing numerous blisters on the lower part of the leg. The discoloration spread out from these blisters, but I am convinced that there was first an occlusion somewhere in the course of the main artery. In a few days a well-defined line of demarcation was formed, about six inches below the knee.

Then came the perplexing question of what was best to be done. With a pulse above 160 and so weak as to be almost imperceptible, temperature of 105.5° F., rapid shallow breathing, and complete unconsciousness, death appeared imminent. Whether "to become executioner" by attempting to amputate in the ordinary way, or to allow her to die without an effort at surgical interference, was the problem which haunted me day and night. Finding no relief from literature, I decided to wait. Accordingly I commenced to poultice the dead limb, at the same time pushing the internal administration of sulphate of strychnine to the limit. The poultices were made large enough to cover every part of the leg from the toes to the knee, and changed every two hours day and night. Contrary to my expectation, she began to improve.

On November 7th separation commenced at the line and advanced rapidly, while healthy granulations soon appeared above. Without a precedent (that I know of) I decided to amputate below the line of demarcation.

Dissecting down carefully between the dead and living flesh, I reached the bones. The patient was still unconscious, and by the use of a small dose of chloral I was enabled to saw the bones, without her knowledge; nor did she know the leg was off for some weeks afterward. Thus nature and I performed an amputation without shock and without the loss of a drop of blood.

There was nothing very reassuring about her condition before the middle of December, after which time she improved rapidly. On May 24th, she having sufficiently recovered to allow the safe administration of chloroform, I split up the stump, turned back the flaps, and sawed off the protruding bones, without losing more than a tablespoonful of blood in the operation. The wound healed by first intention, and she is now, June 22d, able to ride about in a buggy.

I am fully convinced that had I attempted to give

an anæsthetic and amputate in the ordinary way, she would have died during the operation; and I am equally convinced that if more of these extremely weak patients were treated in this way a larger percentage of them would recover.

Clinical Department.

ANTITOXIN ADMINISTERED PER OS.

By J. LINDSAY PORTEOUS, M.D., F.R.C.S. Ed.,
YONKERS, N. Y.

Many of the readers of the Medical Record must have noticed the great dread some children have of the hypodermic syringe, especially the larger-sized syringe used in the administration of antitoxin, and the pain caused by injecting the comparatively large quantity necessary often makes the child scream and twist about (especially when competent assistance is not present), to the actual danger of seriously injuring the patient. In a case of severe diphtheria in a girl of eight years (mentioned below) the sight of my syringe almost caused a convulsive attack, and on no account would she permit me to use it. Having implicit faith in antitoxin and no improvement taking place with other remedies, I thought that if I gave it by the mouth there might be a chance of helping the little sufferer. After boiling a silver spoon I poured the liquid into it; the child swallowed the medicine, and said it had no bad taste and that she would take as much as I liked to give her. The results I will now give from my clinical notes, as also those obtained with other patients similarly treated: S. M——, aged eight years, complained of sore throat on April 28, 1897. I saw her on the 29th of the same month. On examining her throat I could see on the right tonsil four small whitish spots about the size of a pinhead. They at first did not give the characteristic wash-leather appearance of true diphtheria. I prescribed spraying with a saturated solution of boric acid, and a mild laxative. I took a culture from the fauces and on the 30th the bacteriologist reported numerous Klebs-Loeffler bacilli. I ordered the throat to be painted with iron and glycerin. On my visit in the morning of May 1st, the patient said she felt better; she had less pain and she had no fever. May 2d, I found a large patch on both tonsils, of more characteristic appearance. The temperature was 102° F. and treatment was continued. May 3d, 10 A.M., the patches were much larger, extending over almost the whole of both tonsils and a part of the soft palate. The temperature was 103.4° F. At 8 P.M. I gave by mouth one thousand units of antitoxin. May 4th, I found that the patient had slept fairly well, and retained the draught. At 9 A.M. her temperature was normal and the patches of membrane were partly curled up. On May 5th, considerably more than half of the membrane had disappeared. May 6th, very little membrane was left. May 7th, the membrane had entirely disappeared. A culture was taken one week after this, and the bacteriologist reported no bacilli. I consider the case a most typical one, and had it been a unique one it alone might prove that antitoxin is as beneficial when taken by the mouth as when given hypodermatically. But I carried my experiments further and with the same success, as the following brief notes demonstrate:

F. W——, aged eight years, boy, complained of a sore throat on May 6th. May 7th, I found two large patches on both tonsils. The temperature was 102° F. I gave one thousand units of antitoxin by the mouth. May 8th, the temperature was 100° F. The patches seemed much smaller. May 9th, the temperature was normal. There was very little membrane visible, but there was a good deal of tonsillitis. May 10th, the membrane had entirely disappeared. May 15th, the culture showed no Klebs-Loeffler bacilli. Inflammation of the tonsil was much less.

About the same time I treated three other children, in ages ranging from five and six to ten years, in the same way, and all made excellent recoveries.

If this mode of administration has been tried before, I am not aware of it. My object in writing these notes is to prove that the antitoxin of diphtheria is not rendered inert by changes in the stomach, and that this is an easy method of giving it to nervous children.

A CASE OF MUSHROOM POISONING.

By L. L. VON WEDEKIND, M.D.,
[illegible]

The interest attaching to this case is not that in it there is anything new, so far as symptoms or treatment are concerned, but it is in the violent and alarming results following the ingestion of a small quantity of a poisonous fungus.

The patient, aged thirty-seven, an officer in the naval service, is much interested in botany, and up to a short time ago believed himself to be quite an expert in the classification of the different varieties of mushrooms growing in this section. He is a habitual smoker, using strong tobacco in the pipe—which habit has, I believe, blunted to a considerable degree his acuteness of taste. This particular fungus, differing in many ways from those usually found, excited his interest, and he, believing it to be of the variety Amanita, tasted a small portion, intending to expectorate it in the event of finding the pepper taste. Owing to the blunted acuteness of taste he failed to detect the "pepper," and swallowed a small bit of his specimen—calculated to be about one-tenth of the whole. Immediately after swallowing it acute burning of the pharynx occurred, and he realized that it was a poisonous variety. He hurried home, walking about one-half mile, and while on the way was attacked by vomiting and purging. After thoroughly emptying the stomach and bowel he fainted, and was discovered by some men, who brought him around with cold water and assisted him to his home, where he again fainted. The purging and vomiting continued almost constantly for six hours, when I was sent for.

I found him with pupils minutely contracted; pulse, 120; temperature, 105.5° F.; markedly prostrated, and making violent efforts at emesis. He had taken a dose of olive oil and whiskey, which was not retained. He was given a cold bath, reducing the temperature to 102° F.; one-fifteenth grain of atropine, and later one-thirtieth grain of strychnine; also one-half ounce of castor oil and twenty drops of tr. opii. He retained the oil one hour, and then vomited. The pulse eight hours later was 60; temperature, 104° F.; there were constant delirium and hallucinations, very profuse perspiration, very great thirst, and abdominal pain. He could retain nothing on the stomach. Heat was applied to the abdomen and an ice cap to the head, atropine and strychnine were given alternately, and cold baths frequently when the temperature warranted.

This condition—high temperature, slow pulse, great gastric irritation, insomnia, constant delirium and hallucinations, with very marked asthenia—lasted for four days. Morphine was injected in large doses, one-half grain every eight hours, causing some sleep and allaying for a time the great effort at emesis; the stomach and bowel were cleansed with warm boric

solution. I made no effort to feed the patient, as both stomach and rectum were intolerant. Mustard was used quite liberally on the abdomen and hot water bags were applied to the sides and back. The hallucinations were present at all times for a period of seventy-two hours, and these, with the slow pulse and high temperature, caused a suspicion of some cerebral trouble, depending possibly upon the poison for its origin.

After four days the acute symptoms subsided and were followed by a typhoid condition, with a morning remission and an evening rise to 104°–105° F. for about one week, when convalescence was established. The patient showed marked evidence of his illness in his appearance after recovery, but gained very rapidly after the fever abated. Feeding was resumed on the fifth day, clam broth and milk with Vichy water being the main support. Cold baths controlled the temperature.

U. S. N. [illegible], Annapolis, Md.

TRIPLETS.

BY J. TRACY MELVIN, M.D.,

[illegible]

PERMIT me to report, merely for statistical purposes, the following case of triplets, there being nothing unusual except that fact. Mother, aged thirty-four, married fourteen years. Seven children, all single pregnancies. Health good. Labors normal. No plural pregnancies among her relatives. Father, aged thirty-six, laborer; average health and size. One sister had twins once, but the family has not been specially prolific. This pregnancy was marked even in its early weeks by severe abdominal pain of a stretching nature, at irregular intervals. These pains became so severe during the later months as to confine the woman to the bed a part of the time.

I was called on the two hundred and forty-third day after menstruation and the two hundred and thirty-sixth day after the probable date of conception. There was a slight bloody flow with very slight pains in the back. The cervix was effaced and the os was very slightly dilated. It was a vertex presentation. I had previously diagnosed twins. I gave an anodyne and the patient rested well for twelve hours, when a slight labor pain caused the friends to send for me again. The presenting child was born with one pain, the second of the labor; it weighed four pounds. Without tying the cord I waited for the second child, which was born with one pain, breech presenting, five minutes later; weight, three and three-fourths pounds. After tying the cords and instructing the nurse, I turned to examine the mother, who was complaining of the most severe labor pain yet experienced, and found the uterus still large and a third child presenting by the vertex. Two very moderate pains expelled it, a girl, who weighed five and one-fourth pounds. Ten minutes later two placentas were delivered—one weighing twenty-two ounces and connected by two distinct cords with the two children first born; while the second, weighing fourteen ounces, was wholly distinct and connected with the last born. The two children first born presented every appearance of being of at least two weeks shorter gestation than the last born, which was evidently of about eight months' development. The children were thoroughly oiled, their faces and mouths were washed, and they were placed without dressing in a box containing bottles of hot water and plenty of cotton batting. The mother passed an uneventful puerperium with no unusual flowing, and furnished an abundant quantity of milk for all the babies, who are now a month old and have gained eight, nine, and twelve ounces respectively.

ACUTE ARSENICAL MULTIPLE NEURITIS FOLLOWING THE ADMINISTRATION OF FOWLER'S SOLUTION IN A CASE OF CHOREA.

BY PHILIP MEIROWITZ, M.D.,

[illegible]

MAY W——, the patient, is a schoolgirl, thirteen years of age. She came to the clinic, October 5, 1896, suffering from an attack of Sydenham's chorea. This was perhaps the fourth or fifth attack of St. Vitus' dance that she has had. Her first attack dates back three or four years. The second attack occurred about a year ago. During the past twelve months she has had several attacks, with intervals of rest of about three or four months. The arms, legs, and neck were principally involved. The face, excepting the eyelids, escaped. The upper extremities were more affected than the lower. There was considerable weakness in the arms; she could with difficulty hold objects in the hands. For a time her speech was affected. The choreic movements continued during sleep and appeared to be worse than during the day. Sleep was often interfered with. There had never been any mental disturbances aside from a certain degree of dulness. She is thin and undeveloped for her age.

A week and a half before she came to the clinic she complained of a sense of stiffness in the knees, but had no difficulty in walking. A few days later she had the sensation of "pins and needles" in the soles of the feet, the legs became weak, and she experienced severe spontaneous pains in the lower extremities below the knees. Friction of the legs was extremely painful. Walking was interfered with to such an extent that she was confined either to a bed or to a chair during the entire week preceding the visit to the clinic. Shortly after the pains appeared in the legs they were felt in the upper extremities, which also became painful to the touch. It was with very great difficulty that she was brought to the hospital.

Her examination at that time showed the following: Once seated in a chair, it was with the greatest difficulty that she could arise, repeated efforts being unsuccessful. She had to employ the arms, exerting downward pressure on the seat of the chair or seizing hold of some neighboring object. Standing alone or walking unaided was entirely beyond her ability. Her gait was markedly ataxic; the legs were raised somewhat higher than normal, and the toes touched the floor first, the heel following. There was considerable emaciation, which, as the mother of the patient explained, developed rapidly after the onset of the pain in the extremities. The left upper arm was decidedly thinner than the right. This discrepancy in the size of the superior segments of the arms was observed by the mother last summer. At that time and previously the child had made no complaint which might have been referred to this region. Measurements of the upper extremities gave the following:

	Right.	Left.
Middle upper arm.	6¼ inches.	5¾ inches.
Upper third of forearm. . . .	6¼ "	6¾ "
Lower third of forearm. . .	4⅞ "	4⅞ "

The muscles in all of the extremities were quite soft and flabby, and painful to manipulation. The movements on the right side were somewhat better than those on the left. In testing various groups of muscles it was found that the grip was very weak, even when the hand was passively extended. She could not cause the index hand of the dynamometer to move when she exerted her strength. Extension of the fingers was imperfectly performed. She could not spread the fingers well, or accurately touch the tips of

the fingers with the tip of the thumb. There was partial drop wrist. Flexion of the wrist was extremely weak. The movements of the forearms and upper arms were relatively stronger, yet were under the normal. The flexed forearms could be passively extended without the slightest effort, even when the patient exerted herself to the utmost. Extension of the forearm was stronger than flexion, and the patient resisted fairly well efforts to overcome it. The muscles of the shoulder seemed not involved.

Turning to the lower extremities, it was found that the legs below the knees were cold to the touch; the feet were slightly warmer than the legs. The muscles were soft and flabby and hyperæsthetic to pressure, more so in the legs than in the thighs. The knee jerk could not be elicited in either leg. The movements of flexion and extension of the thighs and legs were weak. There were typical drop feet. It was impossible for her either to extend or to flex the feet.

Tactile sensation was in the main normal. There were some slight disturbances to touch in the hands and feet. Sensation to mechanical pain, such as that produced by the point of a pin, was normal; but the pain resulting from the application of a strong faradic current was not felt in the legs by the patient. The temperature sense was not affected; she could easily distinguish between a hot and a cold test tube.

The electrical examination discovered marked reduction of the faradic irritability of the muscles of the legs. The reaction to faradism in the arm muscles appeared normal.

There had never been bladder or bowel troubles.

Since August 17, 1896, when she first came to the clinic—*i.e.*, in the period of seven weeks—the patient has taken four ounces of Fowler's solution. She began with five-drop doses three times daily, and each day increased the dose by one drop, until she was taking fifteen drops. She then began to vomit and there developed some œdema of the eyelids. The dose was now reduced to ten drops, at which the medicine was continued up to a few days prior to the examination, when only five drops were given.

202 West One Hundred and Third Street.

A SOMEWHAT UNIQUE CASE OF SPONTANEOUS FRACTURE OF THE CLAVICLE.

BY THOMAS H. MANLEY, M.D.

On the 16th of September a case of clavicular fracture came under my care, in the West Side German Dispensary, which belongs to a very rare class, and seems to me to be of sufficient interest to be incorporated in the annals of surgical literature.

The patient was a man, thirty-four years old, married, American; by occupation a billiard player. He seemed to be a person of good physique and was free from any organic malady. He denied specific disease, and in no structure was there evidence of tubercle or cancer. He never before had sustained a fracture, said he had never had epilepsy, and was not addicted to excesses of liquor. For the past ten years from time to time he had had rheumatic pains in the knee and ankle joints, but had never had acute rheumatism.

He said he retired the night before in his usual good health, at about eleven o'clock. At about three in the morning he was suddenly awakened by a severe, most distressing pain, which involved the whole shoulder and extended down the arm into the hand on the left side. He was startled to find that he was entirely unable to move the arm without producing the most agonizing pain in the shoulder. The use of thermal applications and liniments only aggravated his condition, as the surface was hyperæsthetic and no motion at the joints could be tolerated.

On examination it was noted that he was pale, of a plaintive expression, with a weak pulse, but had no elevation of temperature. As he stood up the left shoulder was noticed to be much lower than the right, and the hand on that side was carried in an opening of his coat, which supported the arm as a sling. When the chest was stripped, on viewing it from the front a well-marked deformity of the outer aspect of the left clavicle was evident. Now by seizing the arm and making gentle motion, it was seen that there was a complete fracture at the outer third of the left clavicle with considerable overriding of the fragments.

In an examination of the literature on fractures by American and foreign authors, I am unable to find a record of any similar case; the nearest is found in Malgaigne's works ("Traité des Fractures," vol. ii., p. 464). He publishes the case of a young robust woman, who fractured the clavicle by turning over in bed.

All surgeons are agreed that this fracture commonly results from muscular action in any violent motion or exertion of the body or the shoulder; but there is no record of any instance in which, as in this case, muscular contraction was involuntary and the individual was entirely unconscious of any effort.

RITUAL CIRCUMCISION.

BY ARTHUR STERN, M.D.,

[illegible] THE STERN [illegible] SEXUAL, ELIZABETH, N. J.

I was recently called to attend a child, ten days old, who had been circumcised two days previously. Upon inquiry it appeared that the operation—or, more properly, the cutting, since no attempt at stitching had been made—had been done by the ritual circumciser, who directed the family to dress the wound with a piece of lint well soaked in carbolic-acid water! I found the child cyanotic. Its wrappings were saturated with urine of a dark greenish color. The lint dressing had stuck fast to the wound. Around the penis at the scrotum, in the inguinal parts, and wherever the solution had touched the skin, an erythema had developed. I immediately ordered that the application of the carbolic-acid water should be discontinued, that the child should be treated with a talcum preparation, and should have an abundance of liquid, with a view to getting the desired diuretic effect on the kidneys. In addition to this I prescribed a solution of bicarbonate of sodium. The next morning the child was somewhat better; cyanosis had disappeared, and the urine was of a lighter color. The child recovered finally.

Cases similar to the above have been reported by Bogdanik and Melzer.

The rite of circumcision is so firmly intrenched in many minds as a desirable custom—partly for its supposed therapeutic value, but more especially by reason of its religious sanction—that opposition to it would perhaps meet with little result. But it does seem, from the data at hand, that some measure of skill and care should be exacted of those who take upon themselves the task of performing the operation. It is true that great numbers of children undergo this operation every year, and that the reported cases are comparatively few in which death or even serious sickness is alleged to be its result. Reported cases, however, usually have in them something exceptional. It is well known that many minor evils and some very grave ones are justly chargeable to the carelessness and want of skill with which the circumcision is done.

An excellent treatise on the delicacy of this operation, and the danger to life and health involved in its

being carelessly done, is given by Dr. Löwenstein, in vol. 54, part iv., of the *Archiv für klinische Chirurgie*. Dr. Löwenstein is strenuous in insisting that no ritual operator should be allowed to circumcise until he has first received a modern hygienic education and knows something at least of latter-day methods. He submits it to be an outrage that an operation pregnant with so many possibilities to the life and health of the young should be intrusted to an ignoramus. I apprehend there are few physicians who do not share his views.

218 East Jersey Street.

Progress of Medical Science.

The Protective Activity of Anthrax Serum.—Sobernheim (*Berliner klinische Wochenschrift*, October 18, 1897, p. 910) has shown that the blood of oxen, sheep, and rabbits treated with attenuated cultures of anthrax bacilli, and thus rendered immune to infection with virulent anthrax bacilli, appears to contain no specific protective substances. The treatment of rabbits with the serum of such animals was attended with the slightest protective influence. Nor were specific properties found in the blood of oxen that had recovered from attacks of anthrax occurring spontaneously; and a like result was observed in the case of a man. In animals treated for a long time with virulent cultures, however, with the development of active immunity, specific changes in the blood were found. The blood serum of calves thus treated proved capable of conferring only relative immunity upon rabbits, but complete immunity upon sheep.

Recovery from Hemorrhagic Purpura following Treatment with Injections of Artificial Serum.—Pigot (*Gazette Hebdom. de Méd. et de Chir.*, October 17, 1897, p. 990) has reported the case of a debilitated patient who had been suffering for two weeks with symptoms of hemorrhagic purpura and bleeding from the gums. The whole body was covered with hemorrhagic areas, which were especially marked upon the extremities. Blood was also discharged by the bowel. There was complaint of a painful sense of burning in the epigastrium, and the breath was fetid. On auscultation a small cavity was found at the apex of the left lung. The liver was slightly enlarged; the spleen was normal. The temperature was elevated. Ferric chloride, ergotin, and lemons were administered, and a mouth wash of potassium chlorate was ordered, but no improvement followed. Finally two hundred and fifty cubic centimetres of artificial serum was injected subcutaneously, and within twenty-four hours marked improvement had taken place. A second and a third injection of the same amount of fluid were given on successive days, and within forty-eight hours convalescence set in and progressed to ultimate recovery.

Chorea Complicated by Pregnancy Relieved by the Induction of Abortion.—Collier (*Birmingham Medical Review*, October, 1897, p. 243) has reported the case of a married woman, twenty-one years old, with a child a year and a half old, who came under observation suffering from chorea, affecting chiefly the head, the face, and the right arm. The choreic movements had begun six months previously, following a severe fright from being nearly run over by horses. In spite of treatment the movements had increased in severity. On examination it was found that the woman was about four months pregnant. The heart sounds were normal and there was no history of rheumatism. Treatment with arsenic, and later with chloral, bromides, morphine, sulfonal, inhalations of chloroform successively failed, and maniacal symptoms developed, with evidences of exhaustion. The induction of abortion being decided upon, under chloroform the cervix was dilated, the membranes were ruptured, the vagina was plugged, and a hypodermic injection of ergotin was given. Labor failing to set in within twelve hours, chloroform was again administered and the cervix further dilated; two fingers were introduced into the uterus, a leg was pulled down, and a five-month's fœtus delivered, the placenta coming away a few moments later. The uterus was thoroughly washed out with a strong solution of iodine. The temperature rose within a short time to 105.8° F., but was reduced two or three degrees by sponging, and it gradually fell to normal during the following twenty-four hours, five grains of quinine sulphate being given every fourth hour. From now on the patient made rapid improvement, the movements becoming less and less marked, and eventually ceasing.

Hydrophobia of Long Incubation.—Feltz and Archambaud (*Gazette Hebdom. de Méd. et de Chir.*, September 30, 1897, p. 925) have reported the case of a man, twenty years of age, previously in good health, who after several days of dissipation was seized with chill and difficulty in respiration. The temperature was normal, the pulse not accelerated. There was complaint of pains radiating from the sternum, and difficulty in swallowing. In a short while the face became pale, the expression terrified, the eyes deep. There was intense dyspnœa, with pharyngeal spasm and inability to swallow; also precordial pain, radiating toward the left arm. After a while furious delirium set in and sanguinolent froth was ejected from the mouth. Respiration and pulse became accelerated, the pupils dilated, cyanosis developed, and death ensued. A diagnosis of hydrophobia was made, and on inquiry it was learned that the patient had been bitten on the lip six and a half months previously by a rabid dog.

Origin of Pressure Deformities.—Ferd. Bähr (*Volkmann's klinische Vorträge*, No. 194, October, 1897) concludes that Julius Wolff's "transformation theory" is inadequate to explain the beginning stages of these malformations, and maintains that it is to the modified "Hüter-Volkmann pressure theory" that we must look for light on the earlier phases. After the deformity is fairly inaugurated, the author thinks that the Wolff theory comes into play and aids in the adaptation of the misshapen parts to the new conditions. The origin of pressure deformities shows the following steps: 1. Defective action of braces (ligaments, etc.), with lessened power of resistance of bone. 2. Unfavorable pressure, with (*a*) deformity of epiphyses, (*b*) deformity of diaphyses (curvature), or (*c*) both at once in varying proportions. 3. Adaptation of deformed bony parts to the new relations.

Chylous Ascites in the Course of Cancer of the Stomach.—Drs. Hertz and Georges Luys (*La Presse Médicale*, October 9, 1897) report the case of a woman whose history gave no evidence of neoplasm of the stomach. On her entrance to the hospital she presented phenomena of ascites, necessitating abdominal puncture. A white milky liquid was drawn off, the chemical analysis of which showed chylous ascites. At the autopsy cancer of the stomach was found spreading to the pancreas, as well as to the perigastric ganglia, and continuing in the form of a thick vein all along the aorta to the point of origin of the renal arteries. Histological examination of the neoplasm showed it to be typical epithelioma. It would seem in this case, as in the similar instances of Straus and Whitla, that rents in the thoracic duct caused by the cancer were to blame for the chylous ascites. Dr.

Letulle thinks that this case confirmed the necessity of a rigorous differentiation between chylous and chyliform ascites, these two kinds of peritoneal effusions arising from different causes. Letulle mentions a case of temporary chyliform ascites in a woman affected with cardiac cirrhosis. At a given time the ascites was sufficient to necessitate numerous punctures; the first of these would give a clear pale yellow fluid; then without any known cause the liquid would cease to be clear and become chyliform; then this aspect would disappear, and the later punctures would again yield the clear yellow fluid. This does not seem to have any plausible explanation. Dr. Letulle has also observed temporary chyliform ascites in children. Some autopsies have shown that in these cases the chyliferous vessels are damaged; these are then instances of chyliform and not chylous ascites. Dr. Iroisier recalls the fact that he has already reported three cases of cancer of the throracic duct; two of these were not accompanied by chlyous effusion, the third did not even present ascites. Chylous ascites would seem to be the exception in the course of cancerous degenerations of the thoracic duct. Rupture of the thoracic duct seems improbable. The consequences of cancerous infiltration of the walls are in effect a thickening and a diminution of the lumen of the canal, a diminution which has as its consequence a complete and fatal obliteration of the canal. In these conditions it is easy to understand that the thoracic duct cannot rupture. It ruptures only where the structure is normal. Variot thinks that there exists a relation of cause and effect between the *régime* of the patient and the chylous appearance of the ascitic liquid. In a child having chronic nephritis and kept on a milk diet for five months, there followed a chyliform ascites. It is necessary to add that in this case the blood serum was milky, and Dr. Variot thinks that there was a correlation between these different symptoms.

Search for Lead in the Salivary Glands in Acute Lead Poisoning.—Dr. Renon (*La Médecine Moderne*, October 5, 1897) has noted the presence of lead in the salivary glands of two guinea-pigs poisoned with white lead. These were the only positive results obtained from the examination of ten guinea-pigs which had succumbed after receiving for nine days either red or white lead mixed with their food. These facts, analogous to those reported as observed by Ellenberger and Hofmeister in sheep inoculated by injection of plumbic acetate beneath the skin, are interesting by reason of the rôle lead plays in certain forms of parotiditis in man.

The Care of the Perineum in Labor, and its Repair afterward.—Upon the basis of an extended clinical experience, Happel (*Memphis Medical Monthly*, November, 1897, p. 485) offers the following deductions: He insists that the condition of the patient before delivery should be accurately known, in order that all of her secretory and excretory organs may be suitably regulated. If leucorrhœa exists, hot douches, medicated when necessary, should be employed. If the patient be a primipara of advanced years, massage of the perineum and vulva before and during labor will be beneficial. During labor the physician should keep informed by educated touch as to the dilatability and degree of dilatation of the outlet. When labor is normal in every respect, the perineum will need little or no support, but the palmar surface of the hand should be ready to furnish support, should it be needed. When the perineum yields slowly and irregularly, the hand should be ready to give support at any moment, and this support must be given in a proper manner during the least expulsive pains. Chloroform should be employed freely and the woman exhorted not to bear down. In case of rupture, an immediate operation for repair should be undertaken, but for the purpose of determining the fact of a rupture it should not be necessary to subject the woman to indelicate and needless exposure. If educated touch cannot detect laceration, then repair is not needed. If doubt exists with regard to a laceration, careful inspection of the parts should be made. Slight fissures and abrasions do not need sutures. More harm may be inflicted with sutures by invasion of the deeper structures of the canal than good effected by closing these rents in the mucous membrane of the vagina. No other antiseptic is needed in primary operations than water, which should be boiled and used as hot as can be borne by the patient.

Diagnostic Importance of Exact Pulse Examinations.—W. Janowski (*Volkmann's klinische Vorträge*, October, 1897, pp. 192, 193) deprecates the modern tendency to regard lightly the information to be obtained from the pulse, and attaches much importance to the results obtained by an intelligent use of the sphygmograph. He recognizes eighteen forms of arterial pulse, which are to be grouped as follows: (*A*) Pulse whose characteristics are recognizable from the inspection of tracings of a single beat. 1, Pulsus durus; 2, pulsus mollis; 3, pulsus celer; 4, pulsus tardus; 5, pulsus magnus; 6, pulsus parvus. (*B*) Those forms which require for their recognition tracings of a succession of beats. 7, Pulsus frequens; 8, pulsus rarus; 9, pulsus irregularis; 10, pulsus embryocardia (a rapid, short systole, followed by an equally rapid and short diastole, the pause being altogether lacking); 11, double pulse, in which each beat is closely followed by another, a pause then intervening before the next beat (triple and quadruple forms are also found); 12, unequal pulse, characterized by unequal heights of the wave summits; 13, alternating pulse, in which small waves succeed larger ones in a definitely proportionate manner; 14, the so-called pulsus paradoxus, in which the character of the single waves is influenced by respiration; 15, alternating form of double pulse, in which the first of the two beats is larger than the second; 16, hemisystolia, two heart beats giving rise to but a single pulse wave; 17, condition of total arrhythmia, presenting differences in size and rhythm not governed by any rule perceptible; 18, pulsus differens, a pulse different in the two halves of the body. Each of the above is exhaustively but practically treated, and the value of the discussion is furthered by numerous reproductions of pulse tracings taken at the bedside.

Lupus Vulgaris.—A new treatment by currents of hot air has recently been introduced by Dr. Holländer, of Berlin, following out the suggestions for local treatment of various processes by hot vapor. An eschar is produced without involvement of surrounding parts, by simply overheating the diseased area. The instrument devised for the purpose consists essentially in a long, hollow, metallic arm, terminating in a fine point. Through the central opening a current of air is made to pass by means of a rubber bag, like that of the Paquelin apparatus, the extremity having been heated in a spirit-lamp flame. In this way a temperature of 300° F. or over may be utilized. The curative power of this superheated air is attributed to its antiseptic and hæmostatic qualities. It is thus suggested as a means of treatment in gynæcology, as well as for metrorrhagias and infectious processes. Illustrations of lupus before and after treatment are given in *La Presse Médicale*, October 30th, which gives an account of the new method. When applied to healthy skin the current of hot air produces a vasoconstriction causing

ischemia of the region acted upon, while in diseased areas with newly formed vessels such as exist in lupus, there is a rising up of the skin above the surrrounding surface. While healthy skin loses its pallor and regains the previous normal appearance after a few days, the lupus skin begins to mortify. A repetition of the operation several times, it is claimed, results in cure in mild cases, but those of moderate intensity should be kept under observation for three years before lasting cure can be claimed.

The Occurrence of Necrosis of Intestinal Glandular Epithelium in Cases of Diabetes Mellitus.—It is known that necrosis of the epithelium of various glandular organs may take place in cases of diabetes mellitus, and it has been supposed that the lesions were due to the elimination through the affected viscera of certain poisons circulating in the blood. Ludwig (*Centralblatt für innere Medicin*, 1897, No. 43, p. 1,105) reports a case, which he believes to be the first, in which such necrosis was observed in the glandular apparatus of the intestine. The patient was a woman, thirty-six years old, whose father had died of cirrhosis of the liver, one brother of diabetes mellitus, another of some acute pulmonary disorder, and a sister of erysipelas. The patient herself had suffered from repeated attacks of facial erysipelas. For a period of five weeks there had been noticeably increased thirst and an increased sense of hunger, as well as increased elimination of urine. In spite of the ingestion of an abundance of food, there were rapid emaciation and loss of strength. The appetite had, however, become impaired, and there were besides, headache, slight vertigo, and extreme languor. The knee jerks were preserved. The pulmonary percussion note was relatively impaired on the left side above and below the clavicle, and posteriorly above the spine of the scapula, as well as over the lower lobe. In the area first named expiration was accentuated, and in the last enfeebled. There was scanty expectoration, and no tubercle bacilli were found in the sputum. The amount of urine passed in twenty-four hours equalled about sixty-four ounces; the specific gravity was 1.025; a slight amount of albumin was present, together with sugar and acetone. In the sediment were found hyaline, granular and epithelial tube casts. The patient grew gradually worse and death ensued. Upon post-mortem examination the epithelium of the upper portion of the ileum was found discolored in small areas, readily detachable, and in some places actually wanting. Farther down there were transverse losses of substance, with distinct limitation and a hemorrhagic necrotic base. A number of areas of similar appearance were present also in the large intestine. Microscopic examination of the affected portions of intestine confirmed the supposition reached from macroscopic observation, that the lesions consisted in necrosis of the cylindric epithelium of the tubular glands. The appearances corresponded with those of a deep-seated cellular and purulent inflammation of the glandular epithelium, together with necrosis, and the conclusion is reached that the latter was the primary process in consequence of toxic influences related to the constitutional disorder.

Myxœdema in the Adult. Dr. Briquet (*La Presse Médicale*, October 9, 1897) calls attention to the following points as the most interesting in his paper on this subject: "A persistent thirst which yields to treatment is very marked with this class of patients. Marie found it necessary to discontinue the use of the thyroid body in his patient, as it caused an intense thirst. This disease usually follows overwork, prolonged fasting, late hours, and fatigue. It has been known to last nineteen years in spite of little nourishment being taken. We have no method of treatment as yet that can be relied upon. The history of the matter is brief. In 1890 grafts of the thyroid body were tried. Improvement was noted, but there were no cures by this method. In 1891 Murray tried hypodermic injections of thyroid extract. This treatment was then tried by others, and in the thesis of Derrien we find seventeen series of experiments related in detail. Howitz, of Copenhagen, in 1892, administered the natural thyroid gland, and his attempt was crowned with success, and he has many imitators. The thyroid gland of the sheep has two lobes, and Massée advises giving one lobe every day during the first four or five days, then a lobe every other day for two or three weeks. It is necessary to continue to give one or two lobes a week after cure. Vermehren has tried thyroidin, and in 1896 Baumann used thyroidin, also called idiothyrin. It has been this last remedy that has given the best results. The capsules that are employed are prepared with the same gland deprived of foreign elements, fat, etc. We should carefully note the symptoms that come on at the beginning of treatment. With our patients we noted enervation, vomiting, oppression, and severe pains in the limbs. Scarlatiniform erythemas followed by desquamation and pigmentation, urticaria, abundant perspiration, glycosuria, and sometimes a dangerous tachycardia have been noted. Several deaths have been reported, mostly of children, though there have been some fatal instances in adults as well. The necessity of close watching after the first doses cannot be too strongly emphasized. Since we do not know much about the active principle of the thyroid gland or the means of isolating it, the choice of medication will have to remain in abeyance. Thyroid glands may be more or less active, and the preparations will vary accordingly. Different trials made on stout persons give us reason to believe that as a fat reducing agent it is a weak preparation. We think in a general way that in myxœdema it is better to go slowly; the results will be obtained a little less rapidly perhaps, but they will not be the less brilliant for having been attained without danger. The etiology of this condition has been advanced through the researches of Reverdin, who has brought up a number of problems, however, which remain to be solved. Congenital atrophy, extirpation, functional suppression of the thyroid body bring about myxœdema; these are facts which we cannot explain. Does the thyroid body normally destroy a toxic substance which, after the extirpation of this body, accumulates in the blood? Or, on the contrary, does it secrete a substance necessary to nutrition, especially to that of the nervous system? These two hypotheses have been launched, but the fact that complicates research is the concomitance of myxœdema (the suppression of the thyroid body) and the disease of Basedow (hyperthyroidization), which is not impossible. In any case we cannot deny the importance of the thyroid gland in the nutrition of certain organs—that of bone, for example, as the occurence of dwarfishness proves in congenital myxœdema; in osseous lesions noted in animals deprived of their thyroid glands, to which Hofmeister calls attention; of the nutrition of the skin, either directly or more probably through the nervous system; such serious troubles being noted in subjects of myxœdema, in whom the ingestion of the thyroid body causes certain cutaneous affections. Hofmeister has also noted frequent lesions of the ovaries (atrophy or hypertrophy), which explains the entire absence of the menses in this disease. These facts suffice to show that in spite of the numerous works on this subject there is still a vast field for the study of the properties of the thyroid body open to the physiologist."

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, December 25, 1897.

LIVING WITHOUT A STOMACH.

In these days of rapid progress in surgery, hardly anything in the way of brilliant venture in operative procedure is beyond the possibility of triumphant accomplishment. The history of the past compared with that of the present leaves so little to be anticipated that the most visionary prophet is hardly astonished when his wildest dream becomes a veritable reality. Even apparent impossibilities are made to yield to actual demonstration, and still newer and more difficult paths are constantly opening for such as do and dare.

The report of the remarkable case of successful extirpation of the entire stomach, in this issue of the MEDICAL RECORD, is a case in point which merits more than a passing reference. By the courtesy of the operator and the enterprise of our representative at Zurich, Dr. E. C. Wendt, we are enabled to publish for the first time a full and detailed account of this unique and most remarkable surgical feat. At last accounts the patient is still in good physical condition, having survived the operation three months. The result, in view of our generally accepted notions concerning the real value of the stomach, its physiological place in the economy, and the essential vital functions so long claimed for it, will strike all with becoming astonishment. It is rather an unexpected slight to what has always been considered one of the essential organs of the body, and one governing all others with undisputed sway and unquestioned autocracy, to imagine that it may not be of much use after all. Its fabled quarrel with the other parts of the body, in the story of Æsop, would appear in the present light as scarcely more than the mythical hypothesis of a wild and unreasonable fabrication. Whatever we may venture pro or con on the question at issue, the fact appears to be proven that the human subject can live and be reasonably active for months at a time without any stomach whatever, and obtain all the necessary digestion and nourishment from what remains of the intestinal tract. Is it possible that the latter may have a new set of functions not yet understood, or has the importance of stomach digestion been misapprehended and overrated? In any event we are now brought face to face with a very curious demonstration, which destroys the validity of many preconceived opinions and in a great measure nullifies the results of many previous experiments.

In the matter of a brilliant achievement the operation takes a first rank, and the daring and brilliant surgeon will receive the well-deserved congratulations of his peers throughout the world. He has opened the first chapter in a new history of surgical triumphs.

RECENT PERSECUTION OF FRENCH PHYSICIANS AND THE IMPENDING CHANGE IN CRIMINAL LAW.

THE barbarous peculiarities of the French penal code, which still considers every accused person guilty until he has clearly established his innocence, have received a fresh illustration in the case of a prominent physician residing near Paris.

The unfortunate victim of this "simple judicial error," as the French papers flippantly announce, was imprisoned for months on the absolutely unsupported charge of a hysterical girl, that he had taken undue liberties with her. On mere denouncement Dr. Rémond was literally dragged by brutal "police officers" from his private office to the common jail. Then, without being given the opportunity of a hearing, and with no chance of communicating with his lawyers, he was transported to the prison of Mazas. The latter, as is well known, is filled with degraded criminals of the worst class. Finally, after weeks of cruel suffering, the doctor succeeded in obtaining a hearing before a higher court. He easily proved an alibi, having been engaged in actual consultation with several colleagues at the very time of the alleged offence. He was, of course, completely vindicated and honorably discharged. But the law of France apparently allows him no redress, either against the family of the girl who conspired to ruin him or against the magistrate who so unjustly ordered his incarceration.

Meantime the affair is being exploited by the sensational press of Paris, in the interest, not of justice to the wronged physician, but of piquant sensationalism for admirers of prurient details. Bearing in mind our own Barbara Aub case, we do not wish to be overcritical; but at least we have wide-awake medical societies in our country, which can be counted on to take decisive action when, as in this case, flagrant injustice has been inflicted upon an honorable member of the profession.

It remains to be said that this case is but one of several which have recently "happened" in France, and which have attracted the attention of other countries. Even the staid old *London Times* feels called upon to print editorial condemnations of so truly mediæval a state of affairs. However, all this is soon to be superseded by more enlightened and humane methods of procedure.

Dr. Marie Louise Benoit was recently appointed from the civil-service list a medical interne in the Craig Colony for Epileptics at Sonyea.

THE BOARD OF ESTIMATE AND APPORTIONMENT AND ITS RELATION TO THE TAXPAYERS OF NEW YORK CITY.

On the 8th of December, as is well known to the readers of the MEDICAL RECORD, a large delegation of the physicians of the City of New York, supported and assisted by representatives from the Deutsche Apotheker Verein and from the West Side Taxpayers' Association, went before the board of estimate and apportionment to protest against the granting of public moneys for the use of private institutions, notably those of a medical character, and especially such as are connected with medical colleges. Notwithstanding the cogent arguments presented by the spokesmen for these various organizations, the protest fell upon deaf ears; indeed, it would almost seem as though the arguments advanced might just as well have been addressed to the trees in the City Hall Park as to the board, for all the effect that they had upon that body. It becomes, therefore, an interesting point to consider the relation which this board bears to the taxpaying public. The MEDICAL RECORD believes that it stands in the light of a trustee for the city to see that the moneys raised by taxation shall be used for public purposes and not for private ends, no matter how worthy those ends may be. Suppose that any one of the worthy gentlemen composing the board of estimate and apportionment were the trustee of a private estate; the MEDICAL RECORD is loath to believe that he would give one cent of the funds of the estate to a single one of the private charitable institutions upon which the public money was so lavishly bestowed, merely because the institution was such a worthy charity or because the trustee knew the directors of the charity. And yet these gentlemen in their corporate capacity did precisely this thing, and the act, although a public one, is just as culpable as though it had been done in a private capacity. It is high time that attention should be called to the iniquity of this proceeding, which is deserving of reprobation even though the raid on the city's treasury is done in the name of sweet charity, and this action is doubly iniquitous because some of these institutions do not stand in need of the money. The MEDICAL RECORD trusts that the doctors of New York City will not allow the matter to rest here, but will persistently and temperately urge upon the public and the profession the necessity of a decided change in the manner of dispensing public funds for private charities.

PROFESSIONAL TRADES.

THE exact position in the social scale occupied by practising physicians has at last been settled—at least so far as England is concerned—by the courts. Medicine as a vocation has been decided to be a trade. This might have caused no little feeling of injured pride on this side of the Atlantic, were it not for a most timely intervention on the part of one of our leading luminaries in the law. Justice Edward Patterson of the supreme court has just handed down his decision that law is a trade, and not that alone, but that lawyers have degenerated. This is not a strictly *ex-cathedra* dictum and might even be regarded in the nature of a private opinion, since it was expressed in a speech at the Phi Delta Phi Law Club. Words from such an authority, whether delivered on or off the bench, must be taken at their full worth.

We are glad to know from so excellent a source that law too is a trade. Now let our friends of the cloth come out with equal candor and assure us that they too are pleased to keep us company. So much has happened to make the poor devil of a doctor believe that everything combined and conspired against his welfare and happiness that it is really cheering to read that "the lawyer of to-day is a small man, because there is no demand for large ones."

It is the fault of the times in which we live. Professions were a necessity in the good old days. The era of electricity and machinery has seemed to remove the *raison d'être* of much that was formerly useful and ornamental. Let us accept the inevitable and keep cheerfully at work with the sustaining consciousness that lawyers and clergymen are also buckling down to their respective business pursuits, and that when called to attend a judge, supreme court justice, bishop, or priest, we can say to him, "Sir, what is your trade?"

News of the Week.

Petition to Change the Name of the New York York Cancer Hospital.—At a recent meeting of the board of managers of the New York Cancer Hospital a petition was presented, signed by the entire visiting and consulting staffs, to change the name of the hospital in such way as would omit the very objectionable and unpopular word of "cancer" in its title. The appeal was respectfully received and there is a hope that the proper steps will be taken to make the change possible. This is as it should be. The name "cancer" is particularly odious to patients suffering from the disease, and there is no necessity for its application to one of the best equipped surgical hospitals in Greater New York.

Medical-Practice Law in Washington State.—Dr. F. H. Coe, secretary of the Washington State Medical Society, writes that all persons intending to practise medicine or surgery in the State of Washington are obliged to pass an examination before the State board of medical examiners. These examinations are held the first Tuesday in January and the first Tuesday in July. The January meeting is held on the west side of the Cascade Mountains, and the July meeting on the east side. No temporary certificates are granted by this board, and no exception is made to this rule.

Typhoid Fever in Paterson.—During the month ending December 15th the number of cases of typhoid fever reported in Paterson, N. J., was 109. An investigation by the board of health, as already stated, traced the epidemic to an infected milk supply. Seventy of the cases occurred in families supplied by milk from one dairy.

Mr. Ernest Hart, whose serious illness we recently noted with regret, is now, we are most pleased to learn, practically convalescent.

The Public Spirit of a Medical Man.—Mr. Jonathan Hutchinson, of London, who has been described, with much justice and quite seriously, as an "all-around specialist," does not confine himself to medical teaching, but seeks also to spread a knowledge of useful matters among the people. He built some time ago an educational museum at Haslemere, near which he has a country seat, and on Sunday afternoons delivers lectures on scientific subjects. A course recently delivered was on, 1, instinct and habits; 2, epochs in man's history; 3, Browning and his poetry; 4, improved chronology; 5, fungi; 6, life, death, and terrestrial immortality. He now proposes, it is said, to establish a similar institution at Selby, his native town.

Paris Schools.—The restrictions recently placed upon foreign students in the French medical schools have been rescinded and the former liberal policy has been reestablished. American students can therefore matriculate as in the past.

Approval of the Marine Hospital Service.—A resolution was recently adopted in the Georgia Legislature providing that in all future epidemics all quarantine matters be turned over to the United States Marine Hospital Service, and memorializing Congress to pass a national quarantine law.

Strange Action of College Authorities. — Winthrop College for girls at Rock Hill, S. C., has been closed indefinitely, because of the existence of smallpox in the town. It is incomprehensible that the authorities should prefer to break up a large school rather than protect the pupils by vaccination.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending December 18, 1897. Surgeon A. C. H. Russell detached from the *Lancaster* and ordered home on waiting orders.

Philadelphia Pædiatric Society.—A stated meeting of the Philadelphia Pædiatric Society was held on December 14th, the president, Dr. J. P. Crozer Griffith, in the chair. Dr. F. A. Packard reported a case of tetanus followed by recovery. The patient was a boy, twelve years old, and the source of the disease was not recognized, although the mouth was in an exceedingly bad condition and the possibility of infection through this channel was considered. Some of the symptoms were suggestive of hysteria, but after recovery there was no evidence of a neurotic state. Dr. Packard exhibited also two brothers with pseudo-hypertrophic muscular paralysis. Both displayed mental deficiency and it was thought also enlargement of the thyroid gland. Dr. Packard exhibited further a cretin, six years old. Dr. G. Hudson Makuen offered a communication dealing with speech defects in children and methods and results of treatment. He exhibited an interesting group of cases displaying most admirable results from intelligent educational treatment. Dr. E. R. Schreiner read for Dr. R. G. Curtin the report of a case of arsenical neuritis developing in the course of treatment of an attack of chorea with Fowler's solution. Dr. Clara T. Dercum reported a case of idiopathic multiple neuritis in a child five years old. Dr. M. H. Fussell described an otocephalic monster and exhibited the specimen. Nominations for officers for the ensuing year were made.

Obituary Notes.—Dr. G. Perry Reynolds, medical examiner for the town of Guilford, Conn., died on December 9th, aged sixty-eight years. He was a graduate of the New York University Medical School in the class of 1852.—Dr. James O. Van Hoevenberg died at his home on Staten Island, from the results of a paralytic stroke, on December 8th. He was seventy-six years of age.—Dr. Joseph R. Lewi, of Albany, N. Y., died at his home in that city on December 19th. He was born in 1820, and was graduated in medicine from the University of Vienna in 1847. He was attending physician to the Albany Hospital, a member of the New York State Medical Society, and a member and ex-president of the Albany County Medical Society. He leaves two sons, physicians, and one son, a pharmacist, as well as two daughters, who married physicians.—Dr. Joseph F. Edwards died at Atlantic City, N. J., on December 6th, of shock following an operation, necessitated by the result of a kick by a horse some two years ago. Dr. Edwards was graduated from the University of Pennsylvania in 1881, and became a resident physician in the Philadelphia Hospital. He was for three years State prison inspector at Trenton, N. J., and editor of the *Annals of Hygiene* and of the *Daily Lancet.*

Eastern Medical Society, New York.—The following officers were elected for the ensuing year: Dr. William S. Gottheil, *President;* Dr. A. Isaacs, *First Vice-President;* Dr. E. K. Browd, *Second Vice-President;* Dr. B. Gordon, *Treasurer;* Dr. S. Schaie, *Chairman of Committee on Admission;* Dr. R. Abrahams, *Recording Secretary.*

College of Physicians of Philadelphia.—A stated meeting of the section on general medicine of the College of Physicians of Philadelphia was held on December 13th, the president of the section, Dr. J. C. Wilson, in the chair. Dr. Alfred Stengel read a paper on "Delayed Resolution in Pneumonia, and Its Treatment." Dr. M. H. Fussell reported "Two Cases of Death without Discoverable Cause." In neither case did the conditions during life give rise to any anticipation of a fatal issue, and this remained unexplained by the conditions found post mortem.

"The Medical Times."—In the issue for December this excellent journal celebrates its silver anniversary. It was founded a quarter of a century ago, with the main object in view "to bring about a harmony in the medical profession, based upon toleration, upon freedom of thought, upon scientific investigation, and upon that mutual respect and courtesy which would naturally be expected in a learned profession where

there is so little really known and so much to learn." We congratulate our esteemed contemporary upon its twenty-five years of useful activity, and wish it as great success in the years to come as it has won for itself in the past.

Yellow-Fever Inoculation.—Dr. Domingos Freiere, whose claims of the discovery of a preventive and curative vaccine of yellow fever, made some years ago, were not substantiated, has been stimulated apparently by Sanarelli's alleged discovery to try again. The recent application of his serum in Rio de Janeiro has, he asserts, been most successful, having reduced the mortality in over thirteen thousand cases of yellow fever to about 0.5 per cent. In view of this experimenter's previous claims, it will be wise to await a more complete account of these trials before consigning yellow fever to the limbo of forgotten terrors of ancient days.

The Late Dr. William Warren Greene. — Dr. Charles Lyman Greene, of St. Paul, writes that he is making an effort to obtain a complete list of the articles published by his father, the late William Warren Greene, of Portland. The references are scattered and difficult to obtain, and he would therefore regard it as a favor if any of the old students or professional friends of Dr. Greene, who have reprints or references to articles, will kindly advise him concerning them.

The African Arrow Poison.—A British army surgeon, Dr. Macpherson, attached to a military expedition in the Uganda country, claims to have discovered that the injection of a solution of strychnine acts as an antidote to arrow poison, and he says that he has by this means saved many men who had been wounded by these weapons.

Yellow Fever in Jamaica.—It is reported that the epidemic of yellow fever in this island is practically at an end, although isolated cases are still reported in Kingston and some of the coast towns. The authorities are blamed for the severity of the visitation, which is attributed to the policy of belittlement and concealment which they adopted in the beginning, and abandoned only when the deaths of several prominent persons made further concealment impossible. It is said that it will be perfectly safe for Northerners to visit the island after the first of January.

An Example Worthy of Imitation.—*The Citrograph*, of Redlands, Cal., is a journal of a kind of which there are all too few. It refuses to disgrace its columns with medical advertisements of the indecent sort published in most of the secular papers. It is a lamentable fact that such virtue is so rare that examples of it, when discovered, are worthy of being recorded.

The New York Society for the Relief of Widows and Orphans of Medical Men.—The fifty-sixth annual statement of this society has recently been issued. The society took its origin at a social gathering of the profession at the house of Dr. Edward Delafield early in 1842, and a formal organization was completed at a meeting held November 26, 1842. At the close of 1843 the total number of members was sixty. In 1848 the membership was eighty, in 1858 it had risen to one hundred and ten, and in 1870 the roll of membership was one hundred and twenty-five. The members of the society now number one hundred and forty-five, of whom one hundred and eight are life and thirty-seven annual members. The first application for relief was in 1852, and at the present time the number of beneficiaries is nineteen. The funds of the society now amount to $225,615.44, securely invested, and the income for 1896–97 was $9,793.23. The society has extended aid to fifteen widows and four children of deceased members during the past year. Application for membership may be made through the president, secretary, or any member of the society. Under the present bylaws of the society the annuities allowed are: to the widow of a member an annuity of $400 a year, but for every ten dollars or multiple of ten of income an amount equal to fifty per cent. of said income shall be deducted from the annuity. Each child entitled to relief is allowed $100 per annum, subject to the same conditions as a widow.

The Charity Hospital Alumni Association.—The following officers were elected at a meeting of this association, held December 8, 1897: *President*, Dr. Walter B. Johnson; *Vice-President*, Dr. William Leland Stowell; *Secretary*, Dr. Charles J. Proben; *Treasurer*, Dr. Henry H. Schroeder; *Editor*, Dr. A. T. Muzzy.

Obituary.

J. BERRIEN LINDSLEY, M.D.,

NASHVILLE, TENN.

Dr. J. Berrien Lindsley died at his home in Nashville, Tenn., on December 7th, at the age of seventy-five years. He was born at Princeton, N. J., in 1822, his father, the Rev. Phillip Lindsley, having been at one time president of Princeton College and later of the University of Nashville. He received his medical degree from the University of Pennsylvania, in 1843, and immediately thereafter began to study for the Presbyterian ministry, being ordained in 1846. He preached for a time but his love for science was too great. He studied geology under Gerard Troost, and made an extensive geological survey of the Northern and Eastern States. Later he went to Europe and studied in the medical schools of Germany and France. He was one of the founders of the medical department of the University of Nashville. For the last twenty years he was very active in promoting public-health measures. In 1876 he was appointed health officer of Nashville; in 1880 he was elected to the chair of "State Preventive Medicine" in the medical department of the University of Tennessee; in 1877 he became a member of the State board of health.

At the time of his death Dr. Lindsley was a member of the Numismatic and Antiquarian Society, of Philadelphia; a charter member of the American Chemical Society; since 1851 a member of the American Medical Association; a fellow of the American Academy of Medicine; a director in the National Prison Association; a corresponding member of the National Prison Association of France; and treasurer and the Southern member of the executive committee of the American Public Health Association. Dr. Lindsley was the author of many treatises and shorter articles on medical, historical, and theological subjects. A widow and five children survive him.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MEDICAL COUNCIL, NEW PHARMACOPŒIA, PRELIMINARY EXAMINATIONS, UNQUALIFIED ASSISTANTS—ROYAL SOCIETY—UNIVERSITY—MEDICO-CHIRURGICAL SOCIETY'S DEBATE ON PREVENTION OF TYPHOID—CLINICAL SOCIETY'S ADJOURNED DEBATE ON POTT'S DISEASE—MAIDSTONE—SIR W. GOWERS—SIR H. BURDETT—DEATH OF MR. FREEMAN, OF BATH.

London, December 2, 1897.

The General Medical Council continued its sitting for the usual time, and a good deal of routine business was got through and a number of cases of alleged infamous conduct were tried.

More interesting to you will be the announcement that the new pharmacopœia is now only to be seen through the press and will be published early in the new year. The council was assured by those who had had a hand in it that the work will do them great credit, surpassing all its predecessors.

On the question of preliminary education the council proved weak kneed. It is there that more stringency is needed. Several of the preliminary examinations accepted by the council are mere school tests, quite inadequate for entrance to a profession. Dental matters took up a good of time on Tuesday.

The wail of the unqualified assistant is already audible and will no doubt soon be heard throughout the land. But the decision of the council cannot be appealed from, and his occupation is gone. It is admitted that a number of worthy men must suffer, but so it is in other reforms, and no one can dispute that the repression of all unqualified practice is for the good of the public as well as the profession. The council should now seek powers to put an end to the grosser frauds of druggists, abortionists, quacks, and other parasites of the profession.

Lord Lister presided at the annual meeting of the Royal Society, which was held on Tuesday, and at the dinner in the evening. Both functions were successful. The Duke of Devonshire delivered an important speech deprecating the divorce that has too long existed between science and politics, and intimating that the government (of which he is a member) will again introduce its measure for a teaching university in London. This will probably send the proposed Westminster University into the limbo of the score of forgotten schemes that have preceded it. The present London University, a mere examining body, must be propitiated or superseded. Its senate has already invited a conference of the educational bodies which were recognized in the last bill.

The discussion by the Medico-Chirurgical Society on the prevention of typhoid, though it has not added to our knowledge of the subject, has set in order some of the more important points, reinforced the convictions of many, and brought into focus the views of some of our most advanced sanitarians. The opening of the debate was committed to Dr. Vivian Poore, who holds very strongly that the proper way of dealing with sewage is to return the solids to the land and the liquid to our rivers. Having shown how easy it is for our water supplies to become polluted, he remarked that "public water supplies must be regarded as causes of the epidemicity of enteric fever." It must be admitted that when polluted they diffuse the poison with completeness and insure its being brought to our mouths. Hence he urged that as many subdivisions as possible should be arranged and the supplies from different sources should never be mixed. Dr. Poore was obliged to admit that towns would not readily abandon their waterclosets, and that for London it seemed impossible to do so. Nevertheless, he lamented that people were being taught that the most decent way of treating fæces is to mix them with water, whereas they ought to be applied to the land and become a source of wealth and beauty while safeguarding health.

Professor Gairdner said that of late years his experience in fevers had been small, as the Glasgow local authorities had taken over the fever hospitals. He remarked that even now polluted water did not account for all cases, milk being a frequent purveyor of the poison. He mentioned an epidemic among the students which was at once arrested by stopping the supply of milk to the restaurant within the university.

Sir Richard Thorne Thorne took up the cudgels on the part of the water system, and of course had no difficulty in showing the impossibility in large cities of returning all fæces to the soil. He admitted that with thorough tillage there was little danger in applying excreta to the soil—that is normal dejecta; but it remained to be seen whether specific excreta could safely be thus utilized. Dr. S. Martin had been investigating for the local government board the occasional persistence of typhoid in particular localities. He found that typhoid bacilli would grow for only a few days in sterilized virgin soil, but in soil containing sewage, sterilized in the same way, the growth went on for two hundred days. It had been shown by others that in soil containing sewage the bacilli would remain quiescent in the winter and begin to grow rapidly when warm weather returned. He admitted that burning was safer than burial for the disposal of typhoid excreta, and said the best way was to mix them with sawdust and paraffin and burn them.

Prof. Rubert Boyce, of Liverpool, pleaded for systematic bacteriological examinations as the best means of preventing typhoid. The contents of drain and water pipes as well as other possible causes he would have submitted to frequent bacteriological examination. Laboratories have indeed been established for this purpose by some medical officers of health, and their example ought to be generally followed.

Dr. D. S. Davies, of Bristol, gave an account of the recent epidemic at Clifton and Bristol, which he had shown within four days was due to one milk supply. That was cut off and the epidemic subsided. Some rather misleading cases had been shown to occur through other milk venders supplementing their supply from the polluted farm. Dr. Davies would like a law to empower sanitary authorities to inspect and license dairies.

The Clinical Society has devoted another evening to M. Calot's plan of immediate reduction of spinal curvature in Pott's disease. The president opened by reading a translation of the paper submitted by M. Calot, and the secretary followed with some remarks contributed by M. Redard, of Paris, who was prevented from being present. Dr. Redard is much in favor of the operation; he has performed it in forty cases, without a single mishap or any kind of complication. He, however, admitted that all cases were not amenable to the treatment, and he had restricted the operation to those in which reduction was easy. He was utterly opposed to any rough or violent manipulation, and to any attempt to correct ankylosed curvatures.

Mr. Watson Cheyne said he thought the subject was hardly ripe for discussion, and they had to deal not only with deformity but with a disease. There were plenty of cases recorded already to enable an opinion to be formed in due time, and until then he thought it would be better to suspend operating.

Differences of opinion on this matter were expressed by the surgeons present, and Messrs. Jones and Tubby

replied to the criticisms which had been offered on their paper. They both believe in the future of Calot's plan, and consider it the best means of remedying the deformity and, moreover, of treating the disease. Their experience has shown that the theoretical dangers anticipated need not be dreaded in proper cases. They promised to bring forward these cases at a later date, when judgment of the results may be more safely formed.

Maidstone is not yet free from the epidemic of typhoid. Two fresh cases were notified yesterday, bringing the total up to eighteen hundred and seventy-seven.

The dinner in honor of Sir William Gowers was a great success.

Sir H. Burdett maintains his attitude about hospitals, but the indignation of general practitioners is increasing.

Mr. H. W. Freeman, surgeon to the Bath Hospital, and author of the "Thermal Baths of Bath," died on the 21st ult., aged fifty-five years. He was an able and zealous surgeon. Bath delighted to honor him. He was mayor of the "City of the Warm Vale" in 1889. He had a rather rare hobby for a doctor—a studfarm of thoroughbred horses, at which he took a few hours' rest when practice permitted.

"HONOR TO WHOM HONOR IS DUE."

To the Editor of the Medical Record.

Sir: I believe in giving honor where honor is due. As 1897 is drawing to a close and the Medical Record is about to enter upon a new year of usefulness, I wish to thank you for your highly commendable policy in refusing to admit into your reading-pages any advertisements in disguise. I make no accusations. I do not say that the doctor who extols to heaven Blank's iron preparation, or relates his marvellous success with A., B. & Co.'s mixture, gets remunerated for his labor; he may, and then again he may not. He may write his article in perfect sincerity and good faith, simply wishing to render a service to his medical confrères in bringing to their notice the virtues of a valuable preparation. Nor do I say that the publisher necessarily gets a check for printing such articles. But why serve such articles under a heavy disguise? Why sail under false colors? Every one will admit that it is exceedingly disagreeable and trying to one's patience to be reading a presumably scientific article, perhaps to become interested in the course and the details of a severe disease —and then all at once to perceive that the whole thing is a carefully and shrewdly masked eulogy of some proprietary compound. I do not know how others feel about it, but I feel as if I had been imposed upon, as if I had been cheated out of time and mental labor. More than once have I hurled such a journal into the wastebasket.

A recent number of a reputable journal, for the erudition and professional standing of whose editor I entertain the highest respect, contained eight "original" articles. No less than seven contained recommendations for certain proprietary preparations. The eighth contained a recommendation of a newly introduced "modified milk." If this is not a flagrant imposition, what is it? The proper place for such contributions is in the advertising pages of the journals and in the manufacturers' monographs. But if for some reasons they must be printed in the body of a respectable journal, why not at least print them under their proper headings: "The Wonderful Effects of Blank's Iron Preparation in Anæmia and Chlorosis," etc.? Then the reader sees what he is getting, and he can have his choice—to read or not to read.

But the object of this communication was not to criticise others. It was to thank you for giving us a medical journal full of able reading-matter—and reading-matter only—and to assure you that the intelligent part of the medical profession is duly conscious and appreciative of your far-seeing policy.

William J. Robinson, M.D.

111 East One Hundred and Twenty-eighth Street,
December 15, 1897.

THE SPITTING-NUISANCE.

To the Editor of the Medical Record.

Sir: I am of the opinion that any wholesome idea which has for its purpose the benefit of the community at large will bear repetition until it reaches the ear, the eye, irritates all senses of those whom it should concern, and compels them to have this suggestion materialized and brought into life.

I was delighted with the able and timely letter of Dr. W. J. Robinson in your issue of last June, and was waiting to see the fruits brought about by his labors. But, alas! months passed—the hot, summer months—and the same nuisance continues, and no measures have been taken to exterminate it.

Our current medical literature teems with articles about sanatoriums for our tuberculous patients, recommends new methods and drugs, expounds new theories, how to do away with the unpardonable existence of the microbes—and here under our eyes the dissemination of germs of all kinds and denominations is going on without the least hindrance on the part of the authorities. I refer to the spitting-nuisance in our surface cars and other public places. Where shall one spit?

On entering the elevated and some of the cable cars, one sees a "warning" conspicuously displayed in some corner, "warning" us not to expectorate on the floor, and this is issued by the board of health. "It is a timely ordinance," one thinks to himself. But the same one becomes painfully disappointed when his wandering eye fails to discover any substitute which should have accompanied the above order. Where is the logic, the common sense?

This neglect in providing the public with such an indispensable utensil reminds me of an ancient story, which reads thus: "Marcus Licinius Crassus, the Rich, invited once upon a time the famous cynic philosopher, Diogenes, to his palace, with the intention of displaying before him his wealth. The latter accepted the invitation, and, while expressing to his host his admiration of all he beheld, he was taken with a fit of coughing—and spit his raised sputum into the face of the almighty First Triumvir Crassus. In reply to the indignant protest of the latter, the cynic said: 'Sir, this is the dirtiest place in your palace.'"

Now is not this "warning" alluded to above a mere mockery? Is this, again, a law or order imposed upon a public to be violated simply because it cannot physically abide by it? Where shall one spit when there are no spittoons to be found on the floor?

The act of expectorating on floors is so revolting to all senses of decency and propriety, not only to those who are, *nolens volens*, compelled to look at it, but even to the perpetrator himself, that were there any means on hand to avoid it every person of any degree of education would surely avail himself of it and not commit any nuisance.

Hundreds of invalids, afflicted with pulmonary or laryngeal tuberculosis, chronic bronchitis, syphilis, etc., are crowding daily the cars on their way to the large dispensaries—and these people must spit, they must dislodge their expectoration somewhere. They can't help it—this is their misfortune. Shall we

"warn" them not to expectorate, or provide them with properly adjusted spittoons in accordance with modern sanitary requirements? We believe that the latter would be the proper course to pursue. But then there would be no need of "warnings."

Physicians, the public's ever-ready sanitary guard, in their respective societies, and every public-spirited citizen individually, must see to it that charity begins at home; that inasmuch as sanatoriums are concededly an urgent necessity, there is a crying need to spare the community the spitting-nuisance. Half-measures are no measures. To enact laws without offering adequate means to carry them out is to educate citizens to violate laws unwittingly. And the remedy is so simple!

HENRY LEVIEN, M.D.

239 EAST BROADWAY.

VACCINATION BY THE HEALTH DEPARTMENT.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: Is it not possible to correct the abuses to which the profession and the people are subjected by the health department, or must we suffer in silence?

Is it not time that medical men should assert themselves when the health department assumes that the latter are as a body untruthful, and that the name of a reputable physician signed on a schoolboy's certificate of vaccination stands for naught, if not for a lie? Yet such is the fact.

In discussing the question of school vaccination and the inspection of schoolchildren, I learned to-day from one of the health-department vaccinators that they have received the following instructions from their superiors:

That they must vaccinate a certain number (seventeen) of children each day.

And that, as concerns certificates of satisfactory vaccination held by children who have received them from private physicians, they should first vaccinate the child and then look at the certificate!

As a physician and a gentleman I protest against any such high-handed and insolent disregard of a certificate given by me to a patient who pays me for the service, on the part of the health department or any one else. I protest against the injury done me when the health department says to a patient that my certificate is not to be respected, because doctors sign such certificates whether the case merits one or not. If they find any such case let them discipline the man at fault, instead of casting a slur on the profession at large.

As to the duty of vaccinating a given number of cases each day, it leads to an entire disregard of the right of parents to object to having their children vaccinated by the health department's irresponsible young men, who overlook the injustice they do to the people and the profession in their anxiety to draw their salary. It leads to the pitiful state of affairs, wherein a woman, holding in her arms an infant sick with vaccinia and a very sore arm—the result of a health-department vaccination—has her second child (two years old) vaccinated in spite of her earnest plea for a little delay, out of consideration for her difficulty in caring for the infant, because the vaccinator needed one more name to make up his seventeen. This case came within my observation, and I saw this poor woman, in the midst of her troubles, endeavoring to look after her home and care for the two children, both of whom had very bad arms. She told me this story with tears of genuine sorrow.

Have we, have the people, no voice in these matters, or must we bend the back and suffer?

WILLIAM J. GREANELLÉ, M.D.

UNIVERSITY HEIGHTS, NEW YORK CITY.

"SHOULD MINISTERS PAY DOCTORS?"

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: *A propos* of your query, "Should Ministers Pay Doctors?" I would like to relate an incident that happened several years ago in a small town something less than a thousand miles from here. I was summoned one morning to see the son of a local minister. The boy was an only child; he was the idol of his parents, and all their hopes were centred in him. His sickness developed into one of the worst cases of typhoid fever I have ever seen, and I attended him assiduously day and night; for weeks his life hung in a balance, and, in addition to being the physician in the case, I was called upon to do a large share of the nursing. Finally he began to improve, and with care and attention his recovery was assured. The minister and his wife could hardly find words with which to express their gratitude; they fairly wept for joy, and assured me that they were under everlasting obligations to me for having saved their darling. Some time after the case was discharged the minister called to see me and asked for my bill. I told him that I had no bill against him, and that I made it a rule not to charge the local ministers for my services. He left with the most profuse thanks and every assurance of gratitude, etc. Two or three weeks later I met him again: he said he had talked the matter over with his wife, and they had decided that it was nothing but just and right that I should be paid for having saved their precious boy; they were anxious to show their gratitude in a practical manner, and they would feel very much hurt unless I accepted something from them. I told him then to send me whatever he thought would be a proper fee for attending so grave a case, and that I would leave it entirely with him. A few nights after this I returned home from a long and tiresome drive in the country, and had sat down to a cold and scanty supper, when my wife smilingly brought forth a package carefully wrapped and tied, and addressed to me with the compliments of Mr. and Mrs. So-and-So. We were all agog with curiosity and excitement, and couldn't open that package fast enough; we didn't take time to untie the string, we cut it, and after removing sheet after sheet of wrapping-paper came to a pasteboard box—a shoe box. We lifted the lid carefully, and there in the bottom of that box reposed, not a gold watch and chain or a cut-glass vase, but a pineapple—a miserable, little, weazened, shrivelled-up pineapple, that could have been bought anywhere in that county for five cents! I learned afterward that my ministerial friend had been presented with a barrel of them. "Should ministers pay doctors?" They pay me.

JUNIUS F. LYNCH, M.D.

NORFOLK, VA., DECEMBER 13, 1897.

Placenta Prævia.—External version is recommended in placenta prævia, so that, the presentation being made pelvic, the hemorrhage may be arrested by drawing down and keeping up traction on a foot. The version is generally possible, as the placenta prevents the early engagement of the head; after it has been performed, if the os is not sufficiently dilated to admit two fingers, when bleeding begins one must apply a tampon and wait; if the genitals are relaxed, it is generally easy, even without an anæsthetic, to bring down a foot, and by moderate and steady traction to deliver the woman without further loss of blood. If the bleeding be severe and alarming, it is better to employ combined podalic version at once, or to apply a tampon before attempting external version. —BAUMM, *Centralb. f. Gynäkol.*, No. 39, 1896.

Therapeutic Hints.

Tuberculous Laryngitis.—A combination of lactic acid and carbolic acid in glycerin is recommended for tuberculous laryngitis, on the theory that there will be less irritation from the lactic acid, on account of the anæsthetic effect of the carbolic acid.—Dr. Botey, *Kansas Medical Journal*, May 1st.

Diseases of the Bile Ducts.—When it is borne in mind that the bile ducts have only a limited calibre, that the mucous lining is capable of swelling so as to occlude the passage, and that the secretion of bile takes place under very low blood tension (according to Naunyn one hundred and ten to two hundred and twenty millimetres of water), and is therefore arrested by slight backward pressure, it is easy to comprehend how catarrh in this situation should lead to jaundice, though absolute proof of the correctness of the theory is wanting, since simple catarrhal jaundice furnishes no post-mortem subjects.—Dr. Mayo Robson, *Lancet*, May 29th.

To Avoid Complications in Measles.—Take a flannel blanket, wring it out of water as hot as the hand can bear, and wrap the patient up in this with cold cloth on the head. Keep him in pack about twelve or fifteen minutes; then transfer to a dry blanket and allow him to cool gradually; this brings the eruption to the surface and relieves the mucous and serous membranes. If necessary, give antipyretics for fever and sedatives for cough. I have never had any complications with this treatment.—Merrimars, *Kansas City Medical Index*.

The Course of Bronchitis.—Recovery from bronchitis depends greatly upon two things: First, the condition of the bronchial lymphatics, and second, the condition of the nervous system. 1. When the mucus that is poured out in large quantities is not rapidly absorbed, then the case is apt to be prolonged because the reabsorbent glands are not active. In such cases it is a mistake to give remedies that will loosen the cough. A loose cough is apt to be a protracted cough. Lessen the inflammation, and the cough will usually subside. 2. When the nervous energies of the lungs are deranged, that would give us atelectasis in the young and old. Then we may expect a protracted case and complications like capillary bronchitis or broncho-pneumonia, or possibly an asthmatic attack. In true normal bronchitis, the appetite remains. In pneumonia it is lost. This is a diagnostic sign of value. The better the appetite, as a rule the shorter the attack. This fact, doubtless, gave rise to the saying: "Feed a cold, but starve a fever."—Duncan, *Medical Brief*, April, 1897.

Treatment of Nephritis in Children.—Calomel is indispensable. It stimulates the liver to action, and by the increased flow of bile the contents of the bowel are rendered more fluid and the elements to be excreted more soluble in the blood, thus proving less irritating to the kidneys. The salines are of great service as hydragogues. Hot-air baths must be relied upon for their diaphoretic action, as pilocarpine is very uncertain and not to be depended upon. The best method of applying heat is by using an apparatus which will supply hot air under the bedclothes. This can be used continuously, as it does not cause prostration. Liquor ammoniæ acetatis is an efficient remedy in the stage of convalescence, acting beneficially upon the kidneys and the skin. The high tension in the arteries can be combated more efficiently by blood letting than otherwise, its beneficial effect being seen upon the pulse, the nervous system, and the kidneys in the lowering of blood pressure. A very valuable agent is water, given perhaps plain after filtration or boiling, as young children take carbonated waters with reluctance. Given *ad libitum*, and at regular intervals if the patient does not call for it, it acts as a diuretic, without causing any irritation. If refused by the mouth, it acts well as enema if large doses are given. —Tuley.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 18, 1897:

	Cases.	Deaths.
Tuberculosis	181	93
Typhoid fever	26	13
Scarlet fever	215	6
Measles	306	12
Diphtheria	178	20
Laryngeal diphtheria (croup)	4	4
Chicken-pox	32	0

Pneumonia in Childhood.—The respiration in children suffering from croupous pneumonia assumes a peculiar type, being made up of a short rapid inspiration, a pause in the inspiratory position (absent only during rapid breathing), and a jerky, noisy expiration.—Eshner.

Limits of the Power of Hearing.—Lord Rayleigh observed, in a lecture at the Royal Institution on the limits of audition, that one of the latest determinations of the frequency of vibrations to which the ear is sensitive gave the lower limit as twenty-four thousand complete vibrations a second, and the upper as about twenty thousand. These limits are, however, very ill determined, because the matter depends largely on the vigor of the vibration and the individual ear. Old people do not hear high notes which are audible to young persons, and the speaker had reason to believe that infants hear notes which persons twenty or thirty years of age cannot detect. Experiments on the extent of vibration necessary to audition were described, which appeared to show that a vibration having an amplitude expressed in centimetres by a fraction having eight for its numerator, and one followed by eight ciphers for its denominator, could still affect the ear.—*Appleton's Popular Science Monthly*.

Health Reports.—The following statistics concerning yellow fever, cholera, and small-pox have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended December 18, 1897:

		Cases.	Deaths.
Yellow Fever—United States.			
Alabama, Flomaton	December 1st to 14th	2	1
Louisiana, New Orleans	December 5th to 11th	5	
Yellow Fever—Foreign.			
Brazil, Para	November 26th to 27th		14
Cuba, Havana	December 2d to 9th		2
Matanzas	December 2d to 8th		1
Regla	December 3d to 9th		3
Cholera—Foreign.			
India, Madras	October 30th to November 5th		2
Small-Pox—United States.			
Alabama, Birmingham	December 5th to 11th	17	2
Small-Pox—Foreign.			
Cuba, Havana	December 3d to 9th		6
England, Southampton	November 14th to 20th	2	
Russia, Odessa	November 21st to 27th	7	3
Scotland, Glasgow	November 21st to 27th	1	

INDEX.

A

Aaron, Charles D., stomach disturbances caused by hernia of the linea alba in the epigastrium, 736.
Abbe, Robert, the appendix in the interval—a new method of studying it, 37.
Abbott, Clarence G., death of, 673.
Abdomen, contusions of, with visceral lesions, 101; cysts in the wall of the, 500; imperfections in the diagnosis of conditions within the, 510; penetrating wounds of the, 464; stab wound of the, 170.
Abdominal effusions and growths, diagnosis of, 62; operations, local anæsthesia in, 427; retractor, a self-retaining, 71; tumor, removal of a cystic from a child aged seven months, 51.
Abnormalities, do they tend to die out in the course of transmission? 176.
Abortion, criminal, 32.
Absinthe, effects of, 216.
A. C. E. mixture, death from, 704.
Acetonuria, diacetonuria, and butyric acid in the gastro-intestinal troubles of infants and young children, 739.
Addison's disease, fatal case of, in a young girl, 668.
Adenoids, removal of, from the vault of the pharynx, 607.
Adolescence, insanity of, 610.
Adulteration of drugs, 892; of food, 135, 892.
Advertisements that are unfit to print, 707.
Advertising, medical, 397.
Aged, ovariotomy in the, 832; typhoid fever in the, 861.
Ager, Louis C., protection of the dispensary patient, 70.
Agnew memorial pavilion at the University of Pennsylvania, 635.
Aiken, S. C., 705.
Air passages, surgery of the, in children, 608; wounds of the, 686.
Alabama, health resorts of, 769.
Alabama City, Ala., 769.
Alcock, Sir Rutherford, death of, 797.
Alcohol, effects of upon longevity, 891.
Alcoholic drinks, comparative effect of different, 162; meningitis, 801, 825.
Alcoholism, chief nervous affections of, 759; in women, 699; legislation concerning, 175.
Allbutt, Thomas Clifford, notice of book edited by, 423.
Allen, Charles W., a new comedo extractor, 71; a school for favus children, 471; contamination of milk, 34; hygiene of the barber shop, 542.
Allen, George, death of, 749.
Allen, Harrison, obituary of, 749; resolutions on the death of, 856.
Allen, J. Q., gangrene of the leg following typhoid fever, 918.
Allport, Frank, a retinoscopic trial case, 904.
Alopecia, neurotic, 275.
Amazia, bilateral, 160.
Amblyopia, tobacco, 453.
Ambulance ships for the navy, 601.
Amenorrhœa, 785.
American Association of Genito-Urinary Surgeons, 21.
American Association of Obstetricians and Gynæcologists, 498.
American Electro-Therapeutic Association, 490.
American Medical Association, New York the birthplace of the, 288; section on anatomy and surgery, 94; section on obstetrics and diseases of women, 129; section on practice of medicine, 24, 58.
American Medical Temperance Association, 56.
American Public Health Association, 713.
American students in Germany, 672, 684.
Ames, Delano, phlegmonous gastritis following ulcus carcinomatosum of the pylorus, 365.
Amœboid bodies in the blood of vaccinated monkeys and children and in that of cases of variola, 524.
Ampliphone, 506.
Amputations for crushing injuries of the limbs, 284.
Anæmia, discussion on, 61; progressive, pernicious, and secondary, spinal lesions in, 524.
Anæsthesia, administration of, in Great Britain, 722; capitals operation without, 284; death from general, 632; ideal, 445; improvement of general, 835; paralysis, 697; the discoverer of, 790; war by, 528.
Anæsthetic, local, 758.
Anastomosis, intestinal, pathological histology of end-to-end approximation after the use of the Frank coupler, 401; uretero-ureteral, 905
Anatomy, some anomalies in, 484; some thoughts on teaching, 196.
Anderson, R. Harcourt, rough notes on some anomalies in anatomy, 484.
Aneurism at the apex of the heart, 320; deep-seated thoracic, treatment of, 758; dissecting, of the aorta, 31; of the internal carotid within the cranium, successful treatment of, by ligature of the common carotid, 887; of the internal maxillary treated by ligature of the common carotid, 434; of the middle cerebral artery, 716; of the sinus of Valsalva, 320; of the thoracic and abdominal aorta, 320; rupture of aortic, 679; treatment of, by increasing artificially the coagulability of the blood, 667.
Animals, cruel treatment of, in transportation, 565.
Ankle, the pegleg as a protective apparatus in diseases of the, 206.
Anthrax in Pennsylvania, 351; protective agency of serum of, 922.
Antisepsis and asepsis, difference between, 581.
Antiseptic, mustard as a, 788.
Antivivisection movement, immorality of the, 161; pledge, 508.
Antrum, empyema of the, 540; non-operative treatment of chronic suppurative disease of the, 437.
Aorta, aneurism of the thoracic and abdominal, 320; dissecting aneurism of the, 31.
Aortic regurgitation, different varieties of, 523; valve with two segments, 282.
Aphonia, hysterical, 86, 701.
Apoplectic attack, some unusual forms of the, 689.
Appendicitis, 358, 503; complicating pyosalpinx, 464; differential diagnosis of, 99; disposal of the stump in operations for, 828; frequency of spontaneous recovery from, 522; introducer of the term, 505; is free use of the knife necessary in the treatment of? 231, 243; modified incision at the outer border of the rectus muscle for, 837; operations for, 207, 566; pain, opium, 848; pathology of recurrent, 125; peculiar case of, 704; post-operative hernia after, 609; relapsing, 425; simulation of, by a pus collection in Meckel's diverticulum, 800; specimen of, 65; unusual cases of, 570.
Appendix, absence of the, 570; amputation of the, by gangrene, 566; and cæcum, intussusception of the, 360; curious condition of the, found at operation, 566; in the interval, new method of studying the, 37.
Aqua Tofana, 108.
Arizona, health resorts of, 770.
Arkansas, Hot Springs, 770.
